## Authors of Volume 12

**Dr W. E. Boles**

*Scientific Officer and Collection Manager, Ornithology Section, Australian Museum, Sydney, New South Wales, Australia.*

**Dr K. J. Caley**

*Evolutionary Biologist, School of Education, University of Nottingham, Nottingham, UK.*

**P. Clement**

*Field ornithologist and freelance consultant, Wisbech, Cambridgeshire, England.*

**Dr N. J. Collar**

*Leventis Fellow in Conservation Biology, BirdLife International, Cambridge, England.*

**Dr A. G. Gosler**

*Lecturer in Biological Conservation, Institute of Human Sciences, and University Research Lecturer, Department of Zoology, both University of Oxford, Oxford, England.*

**P. A. Gregory**

*Professional bird guide and field ornithologist, Field Guides Inc. & Sicklebill Safaris, Kuranda, Queensland, Australia.*

**Dr J. S. Matthew**

*Senior Ecologist, HLA-Envirosciences Pty Limited, Melbourne, Victoria, Australia.*

**Dr R. A. Noske**

*Senior Lecturer, School of Science and Primary Industries, Charles Darwin University, Darwin, Northern Territory, Australia.*

**C. Robson**

*Norwich, Norfolk, England.*

**I. Rowley**

*Formerly Editor Emu and Honorary Research Fellow, CSIRO Division of Wildlife & Ecology; Guildford, Western Australia, Australia.*

**Dr E. Russell**

*Formerly Honorary Research Fellow, CSIRO Division of Wildlife & Ecology; Guildford, Western Australia, Australia.*

**Dr H. S. S. Thompson**

*BirdLife Africa Partnership Secretariat, BirdLife International, ICIPE Campus, Nairobi, Kenya.*

---

*Archaeopteryx* is the archetypal 'primordial bird' of the Late Jurassic. This photograph shows the Berlin specimen, found in 1877, one of ten fossils that constitute all the known remains of the Solnhofen Archaeopterygidae. There has been debate as to whether the remains represent a growth series of a single species (as discussed in Chiappe & Dyke 2006) or constitute several different species, or even genera, within the family Archaeopterygidae (Elzanowski 2001, 2002).

## Foreword

## Fossil Birds

### Introduction

Today, there are estimated to be some 9800 species of birds on Planet Earth. This is only a window on the evolution of the class Aves. With those known in the fossil record, it can be increased to about 12,000 species, though about a third of these fossil species come from unknown lineages. Pierce Brodkorb estimated in 1959 that about 1,634,000 species of bird had existed over the 150 million years of avian evolution. We therefore know of well under 1%. However, our understanding of bird evolution is improving, particularly with the discovery of such fossil-rich sites as the Cretaceous deposits of northern China and the early Tertiary deposits of the Messel and Quercy, in Europe, and the Green River Formation of Wyoming, North America, while fossil collecting in other areas, such as Australia, has added to our knowledge of the diversity of the birds that once existed. What follows is a very brief summary of avian diversity, starting with the basal Urvögel, moving through the early Pygostylia and other non-carinate species, before ending with a broad survey of the modern birds—the Neornithes—which include all the bird species alive today.

Before beginning, special mention should perhaps be made of certain fossils that are regarded as contentious. Of particular significance is one such fossil, *Protoavis texensis*, as this species was hailed by its discoverer to be the primordial bird (Chatterjee 1994, 1995). Originating in the Triassic, it would have knocked the most famous of all basal birds, *Archaeopteryx*, off its pedestal as the oldest bird, predating it by over 100 million years. However, severe doubt has been cast as to its avian status, with indications that it is actually an early coelurosaur—just as significant palaeontologically, but not as a bird (Witmer 2002). *Archaeopteryx* is still holding onto its title of ‘the oldest fossil bird’—for now.

Time chart showing the major eons, eras, periods and epochs, with ages (after the UNESCO International Stratigraphic Chart). Added information includes the timespan of birds.

| Eon         | Era         | Period        | Epoch         | Age (Mya)       |       |               |

## Avian Origins

In 1861, a chicken-sized fossil from Bavaria turned the scientific world on its head. Named *Archaeopteryx lithographica*, this animal had the feathers and wings of a bird, but the body, tail and jaws of a reptile—even its wings had hands and claws, and so it was hailed as ‘proof’ that birds evolved from reptiles. It was not until much later that the true significance of *Archaeopteryx* was revealed, when comparisons were made with those of the coelurosaurian dinosaur *Compsognathus*. Indeed, so similar are these fossils that without its feather impressions, *Archaeopteryx* could have been regarded as just another compsognathid dinosaur, if a rather odd one. The discovery of *Archaeopteryx* spurred a debate over the origins of the class Aves that lasted until the late 1990s, when several small dinosaurs, from the primitive *Sinosauropteryx* to the dromaeosaurid *Microraptor*, were found in sites across northern China. Each dinosaur was covered by integuments that were obviously feathers (Chen *et al.* 1998, Xu, Zhou & Wang 2000, Xu, Zhou, Wang, Kuang *et al.* 2003). Thus, possession of feathers is not indicative of being a bird, but is a primitive (‘plesiomorphic’) state within the coelurosaurian theropods; even primitive relatives of *Tyrannosaurus* had proto-feathers (Xu *et al.* 2004). Rather, it is the possession of flight, contour and down feathers, and the combination of a variety of other skeletal modifications that separate birds from their closest relatives within the Dinosauria. *Archaeopteryx* and its kin still act as a morphological bridge, bearing a mosaic of primitive reptilian features such as teeth and the long bony tail without a pygostyle alongside more modern bird-like features, including asymmetrical flight feathers on the wings. The more we find out about dinosaurs such as *Microraptor* and its relatives, the more we realise that the distinction between birds and dinosaurs is an arbitrary line based on no single, unique feature. We know that the pygostyle is not a uniquely avian feature either and is found in a number of oviraptorosaurs as well (e.g. Barsbold *et al.* 2000). We know that the wishbone, or ‘furcula’, is found in many theropods, including *Tyrannosaurus*, one of the most advanced members of that group. There is also evidence that pneumaticisation of the bone—the evolution of hollow bones supported by internal struts—is a theropod characteristic, not a purely avian one. However, no non-avian theropod found so far has all these traits in one skeleton, while the fusion of the trunk vertebrae and the supporting struts of the ribs are uniquely avian. The closest relatives of the birds, the Dromaeosauridae, possess a suite of other features that can shed light on how birds themselves came into being. If we take a closer look at the arboreal *Microraptor gui*, for example, we find that not only does this tiny dinosaur have flight feathers, but it has them on all four legs. These feathers are asymmetrical in form, like those of modern birds. Yet, this is a bona fide dinosaur, not a bird. *Microraptor* has given credence to the ‘tree-down’ hypothesis of bird origins, which had floundered through the lack of examples of arboreal dinosaurs. Until *Microraptor* was discovered, the alternative theory, the ‘ground-up’ concept, was gaining favour, despite there being so many problems as to how this could be the accurate scenario, given that all modern species of flying and gliding organisms are plesiomorphically arboreal. It has since been suggested that the initiation to flying came through these tiny animals jumping about in the branches of the trees of their forest home, with the hindwings forming feathered ‘edges’, which aided lift. The four-winged approach to gliding in this dromaeosaurid came as a complete surprise and led to the re-examination of *Archaeopteryx* and later forms (Christiansen & Bonde 2004, Zhang & Zhou 2004), which revealed that their leg feathers still bore some similarities with those of *M. gui* rather than with the more typical contour feathers that we see today on the legs of birds. Although there are still several opponents to the ‘birds-as-dinosaurs’ theory, general opinion is that the evidence for birds being descendants of theropod dinosaurs is overwhelming.

Despite all of the recent discoveries in China, the Archaeopterygidae are still regarded as the oldest known group of birds, although they are not regarded as directly ancestral. There are still a large suite of reptilian features in the skeleton, including a reptilian physiology, a ‘reversed’ pelvis more similar to their Saurischian ancestors, an unfused rib cage, and a long, bony tail. Also unlike modern birds, the most notable feature is the lack of a horny beak. The recent description of a tenth specimen has revealed more about *Archaeopteryx* and may throw our interpretation of the evolution of birds through a new twist: this example reveals features not shown in the others, clarifying the position of the four toes in relation to each other and, more amazingly, the presence of a ‘switch-claw’, otherwise found only in the dromaeosaurs and the fossil bird *Rahonavis*. Cladistic study also indicates that this discussion on fossil birds should include the dromaeosaurs and the related troodontids as both would be classed as members of the Aves if this is defined as the clade including the ancestor of *Archaeopteryx* and the birds (Mayr, Pohl & Peters 2005, Mayr, Pohl, Hartman & Peters 2007), rather than lying outside the group phylogenetically (as per Sereno 1999),

Several tree-dwelling dinosaurs have been discovered recently in Cretaceous rocks in northern China (Xu, Zhou & Wang 2000, Xu, Zhou, Wang, Kuang et al. 2003; Zhang et al. 2002). Among the best preserved are those fossils of *Microraptor*, in particular *M. gui*. This tiny arboreal dromaeosaurid had a long tail with pennaceous feathers towards its distal end. Such vaned feathers were also present on the forelimbs and hindlimbs, giving the animal a four-winged mode of gliding, or even limited powered flight, between the branches in its forest home.

The members of *Archaeopteryx*, including *A. lithographica*, were birds found in tropical coastal scrubland surrounding extensive networks of coastal freshwater and brackish lagoons. The claws on its feet indicate that it spent much of its time on the ground below the shrubs and trees and that *Archaeopteryx* was, at best, a facultative percher.

*Confuciusornis sanctus*, collected from Liaoning Province in northern China, is remarkable for a number of features, from its comparatively short bony tail to its horny beak. This species may have shown sexual dimorphism, with males (above) perhaps being larger and having long tail streamers.

although there is still debate as to whether this is an accurate interpretation (Corfe & Butler 2006, Mayr & Peters 2006). *Archaeopteryx* itself had poorly-developed flight muscles and could not fly as well as modern birds. Its long tail shifted its centre of balance behind the wings, again unlike modern species. Its claws tell us two different tales. Those on the wings were adapted primarily for climbing, while those on the hindlimbs suggest a ground-based animal. Current consensus is that *Archaeopteryx* was primarily terrestrial, but may also have been a facultative percher, if it perched at all (Mayr et al. 2005). *Archaeopteryx* inhabited a coastal scrubland of low-growing conifers, cycads and similar species, intermingled with more tree-like species such as firs and ginkgos. This vegetation was concentrated around shallow coastal lagoons that abounded in Europe in the Late Jurassic. It may be that, at the coastal edge, as around Solnhofen, the habitat was more open than that known to exist further 'inland' during the period. *Archaeopteryx* may have utilised its limited flight capabilities in the open spaces, adopting a ground-hugging flight pattern (O'Farrell et al. 2002). *Archaeopteryx* was also unable to perform a sudden halt, instead needing a short runway to come to a stop. All this suggests that *Archaeopteryx* flew between areas of vegetation, landed on the ground, then clambered into the bushes to reach food, or to escape predators.

For more than 100 years, *Archaeopteryx* was the only basal bird known to science. Then, in 1995, news came out of Liaoning Province, China, of Early Cretaceous birds that bore many similarities to *Archaeopteryx*, but had just as many differences. These were named *Confuciusornis sanctus*. About the size of the Eichstätt specimen of *Archaeopteryx*, these new birds were toothless, with evidence of jaws covered by a horny beak, while they possessed a short tail. Feather impressions were preserved around many of these fossils, revealing two types of tail feather: many had short tail feathers, but some had long strap-like tail streamers. These may represent immatures and adults or, the more popular interpretation, they represent females and males, respectively: *C. sanctus* may therefore be the oldest species of bird known to show sexual dimorphism. Like *Archaeopteryx*, *Confuciusornis* had forelimb claws, but in this species they were relatively more robust, although its climbing abilities have been questioned (Chiappe et al. 1999, Peters & Ji 1999). There are further modifications to the hand, in that digits I and III are strengthened, while digit II is more slender, probably being used in life to facilitate the bird's gliding ability, suggesting that the species was better adapted to flight than *Archaeopteryx*, although neither had the capabilities of modern birds. Hundreds of specimens of *Confuciusornis* have now been found at the sites. It is known that the area of Liaoning was an extremely turbulent place in terms of volcanic activity during the Early Cretaceous, and it may be that a mass-mortality event has been preserved in the fossil record. Alternatively, this collection of fossils may represent a colony, indicating that *Confuciusornis sanctus* was, in fact, gregarious. A second, smaller, species, *C. dui*, has also been described, and is the earliest fossil bird recovered with its keratinous bill intact. Two others were also described within the genus, but reanalysis of the family has concluded that these were misinterpretations of fossils of *C. sanctus* (Chiappe et al. 1999). *Confuciusornithidae* does contain one other species that has stood up to analysis. In fact, it has been classified as separate generically: this is *Changchengornis hengdaoziensis*, from the Chinese Late Cretaceous (Ji et al. 1999). This family was recovered from deposits within what is known as the Yixian formation (Chiappe et al. 1999, Zhou et al. 2003). These deposits, together with those of the Jiufotang deposits, constitute the 'Jehol Biota' and cover much of eastern Asia. The palaeoecological picture of the region is one of a diverse biota, with a large variety of vertebrates and early forms of flowering plant. These are preserved in ways that suggest that they lived in a predominantly marshland or wet-forest environment and that, in some areas, for instance around Liaoning, catastrophic mass-mortality events occurred that allowed the preservation of whole communities. These Cretaceous deposits provide evidence for the co-existence of different higher groups of birds, exhibiting a mosaic of avian features that constitute different degrees of evolution. Contemporaneous with *Confuciusornis*, for instance, were: the basal enantiornithine *Protopteryx*; its more advanced relatives, such as *Jibeinia*; basal carinate (modern-type) species, such as *Liaoningornis*; and the more advanced wader-like *Hongshanornis*. Meanwhile, the more derived *Changchengornis* of the Late Cretaceous lived alongside primitive basal birds like *Jeholornis*.

Perhaps special mention should be made of two of the basal birds, namely *Jeholornis prima*, and another, rather enigmatic, basal 'bird' from Madagascar, *Rahonavis ostromi*. While the exact position of *Jeholornis* within the class Aves has been questioned, the identity of *Rahonavis* even as a bird has come under scrutiny. Today, there are two camps, one which regards it as a bird (Chiappe 2002, Chiappe & Dyke 2006, Forster et al. 1998, Zhou & Zhang 2002b) and one which feels that it is better placed immediately outside this grouping (Holtz 2000, 2001), possibly within *Dromaeosauridae*.

itself (Clark *et al.* 2002, Makovicky *et al.* 2005). Some have suggested that dromaeosaurs may be more closely related to *Confuciusornis* and all other 'Pygostylia' than they are to *Archaeopteryx*, putting them within the radiation of what we call 'birds' (Mayr *et al.* 2005). Both birds had wing-claws and long reptilian tails, but there the similarity ends. The Chinese *Jeholornis* had a primitive lower torso, but possessed an advanced scapula similar to modern birds, suggesting a better capability of flight than *Archaeopteryx*. It was probably an arboreal species. The stomach contents are well preserved in this fossil, and indicate that *Jeholornis* fed on seeds (Zhou & Zhang 2002b). The remains of *Rahonavis* include a remarkable sickle-like claw on the second toe of the foot (Forster *et al.* 1998). At the time of discovery, this claw added a major feature to the debate on bird origins, for the only other animals that had been found with such a claw were the dromaeosaurs. It has now been described for the most recently discovered specimen of *Archaeopteryx*, providing more evidence for a relationship between the two groups (Mayr *et al.* 2005). The only other elements of *Rahonavis* to have survived are the basal vertebrae of a long tail and the upper arm bones of the right wing. Therefore any reconstruction of this species is purely supposition, although it might not be too far-fetched to suspect that the species was predatory.

### The 'Opposite Birds'

In 1981, Walker described a new major radiation of Cretaceous birds, which he called the Enantiornithes. He also nicknamed these the 'opposite birds', as one insignificant-looking, but immensely important, skeletal characteristic separates the enantiornithines from all other birds: the nature of the fusion of the tarsometatarsus. In modern birds, the fusion occurs towards the foot (distal) end, rather than the body end, i.e. it shows a 'disto-proximal' fusion. In the 'opposite birds', the fusion occurs at the body end, i.e. the opposite way round. Like the Urvögel and confuciusornithids, the Enantiornithes possessed wing-claws and a reptile-like growth-rate and physiology, both of which caused earlier researchers to group these three lineages into the Sauriurae. However, this interpretation was in error: the Enantiornithes are, in reality, the sister-group to a lineage containing all modern birds as well as such famous toothed species as *Ichthyornis* and *Hesperornis* (Chiappe & Dyke 2002). The phylogenetically important Enantiornithes are also important ecologically, for they were the dominant avian group in the Cretaceous. In their heyday towards the end of that period, the Enantiornithes occupied as diverse a set of niches as modern birds, while they were also distributed across every continent. The most primitive member of the group, the starling-sized *Protopteryx fengningensis*, was discovered in the same Early Creta-

Enantiornithes (opposite birds)

The Enantiornithes, or 'opposite birds', were a major constituent of the bird fauna in the Cretaceous, and were the most speciose group of Early Cretaceous birds in China (Chiappe & Dyke 2006). However, they had completely disappeared by the beginning of the Tertiary. Early enantiornithines were small, toothed arboreal birds. One of the Chinese species, *Protopteryx fengningensis* exemplifies these early species, but in addition has some unusual features, such as the two tail-strap 'ribbons'.

ceous formations as the confuciusornithids (Zhang & Zhou 2000). Other primitive enantiornithines are known from Spain, including the thrush-sized *Iberomesornis romeralli* (Sanz *et al.* 1988) and the goldfinch-sized *Eoalulavis hoyasi*, and Australia, in the form of *Nanantius eos* (Molnar 1986). The enantiornithines possessed a mosaic of primitive and modern characteristics, a common feature among basal birds. Even *Protopteryx* exhibited a mosaic of features, including wing claws, and a keel and procoracoid to which powerful flight muscles were attached, and asymmetrical flight feathers (Zhang & Zhou 2000). However, *Protopteryx* is marked out among the Enantiornithes by the possession of some very unusual, barbless, strap-like tail feathers, the nature of which has been found in only a few other species, most notably as the elongated central tail feathers in *Confuciusornis*, whilst something superficially similar is found in a few members of the modern Paradisaeidae. Like *Confuciusornis*, the tail ribbons of *Protopteryx* may have had the primary role as a counterbalance to the body, as both birds possess remarkably short tails otherwise. It is possible that they may also have been used for display. What *Protopteryx* does share with other early enantiornithines is its small size, few small teeth, fairly well-developed wing-claws and a perching habit. Later species were much larger: for example, *Enantiornis leali* from the Late Cretaceous of Argentina had a wingspan of about 1m (Walker 1981). They were also toothless and had reduced wing-claws—in *Halimornis thompsoni*, a seabird of the Cretaceous American Interior Seaway, these claws were so reduced as to be vestigial (Chiappe *et al.* 2002). A few enantiornithines have provided us with direct evidence of their diet. *Eoalulavis*, for instance, as well as being celebrated as the earliest bird with an alula, is also the earliest bird so far discovered to still contain the remains of its last meal in its stomach, in this case small, aquatic, crustaceans (Sanz *et al.* 1996). For the majority, however, we have to look at their skeletal morphology and compare it with modern examples to work out what they may have fed on and how they lived generally. For instance, the possession of small teeth in some of the more primitive species may signify an insectivorous diet, as may have been the case with, for example, *Protopteryx*. Other species, such as *Sinornis santensis* and *Boluochia zhengi*, both from Cretaceous China, had adopted a raptorial lifestyle, and may have occupied the niche held today by shrikes and small falcons (Hou 1996, Zhou 1995).

### Other Toothed Birds

Early Ornithurae  
38 species, 34 genera

Among the early Ornithurae were a group of flightless, possibly fish-eating, seabirds known as the Hesperornithes. Although diver-like in morphology, they were not related. They are thought to have possessed lobed feet, which were capable of rotating sideways, as with the modern grebes (Feduccia 1996). *Hesperornis regalis* was one of the largest in the group, and lived in the Cretaceous Middle American Seaway.

Another group of birds arose in the Cretaceous that differed from their contemporaries through the lack of growth rings in their bones: in other words, their physiology was not of the reptilian type characteristic of the Enantiornithes, confuciusornithids and Urvögel, but was more avian in form (e.g. Chinsamy *et al.* 1998). These primitive 'Ornithurae' belonged to a new radiation that included the ancestors of the Neornithes, or modern birds. They contained some of the most famous of bird fossils other than *Archaeopteryx*, namely *Ichthyornis* and *Hesperornis*. There are a plethora of forms in addition to these marine species, among which are included *Apsaravis ukhaana*, from semi-arid dune systems of Mongolia, *Patagopteryx deferrariisi*, a flightless bird from Argentina (Chiappe 1996, Chiappe & Dyke 2006), and *Gargantuavis philoinos* of Europe, comparable in size to an ostrich (Buffetaut & Le Loeuff 1998). These toothed birds died out by the end of the Cretaceous. The most recent of the group, listed purely by its museum number, was a Belgian specimen dating from 800,000 years before the Cretaceous-Tertiary (or 'K-T') boundary. It was similar in form to *Ichthyornis*, if somewhat larger, but it was too fragmentary for proper placement (Dyke *et al.* 2002). *Ichthyornis* is perhaps the archetypal toothed flying bird. In a monograph on fossil birds in 1880, Marsh listed seven species in the genus, but these were based on a set of rather arbitrary decisions, one of which involved size differences between the specimens. The first major revision of the genus was performed by Julia Clarke in 2004, when she reduced these seven American species to one, namely *I. dispar*. At the same time, she showed that some of the bones attributed to the genus came from birds more closely related to modern birds than they were to *Ichthyornis*. Indeed, one specimen may be a close relative of the Galliformes, and therefore within the neornithine radiation, the more remarkable given its Late Cretaceous age. The interpretations of the general morphology of *Ichthyornis* remain similar to those described by Marsh, although it is now recognised that the American species was quite variable in size. In summary, *Ichthyornis* was a small Cretaceous toothed seabird with tern-like proportions, including powerful, elongate wings, an elongate bill and small legs and feet. Whether it was a pelagic species of the Cretaceous North American seaways, or whether the bodies merely floated to these deep sea positions from more coastal origins, remains a matter of conjecture. *Ichthyornis* has been described from the Old World and

as far south as Antarctica (see Feduccia 1996), but as yet these specimens have not been compared directly with the American skeletons, so no conclusions can be made as to their relationships or even specific identities. The other major grouping, the Hesperornithes, were also marine birds, like *Ichthyornis*, but there the similarity ends. These were foot-propelled divers, and those so far discovered were all flightless, with vestigial wings and the lack of a sternal keel. The hesperornithids and their kin ranged in size 'from that of a large grebe to the largest of the living penguins' (Feduccia 1996): the American *Hesperornis regalis* has been estimated at 1.5m in length, while *H. rossicus*, from Kazakhstan and Sweden, was even larger. These birds have been likened ecologically to divers, with a diver-like morphology, similar postures, poor mobility on land and a fish-based diet. However, they also differ in a number of ways. For instance, they had a toe rotation convergent on that of the grebes and, like them, probably had lobed feet, rather than webbing. Unlike either group, the hesperornithines were more marine, possibly nesting in colonies on islets and isolated coastlines. Their flightlessness also sets them apart from the divers and most grebes: their bones were more dense than these neornithines, making them better adapted to diving. It may have meant that the birds 'sat' in the water lower than most modern birds, with comparisons being drawn with the subsurface swimming technique of anhingas. The hesperornithines included several species from a number of families, the most familiar of which is the American *H. regalis*, but with more slender relatives such as the Baptornithidae and the primitive *Enaliornis*. Although they disappeared at the end of the Cretaceous, their place was rapidly taken by diving birds from the neornithine groups in the early Tertiary, if not at the end of the Cretaceous.

*Ichthyornis dispar* represents an alternative Cretaceous seabird morphology to that of the flightless hesperornithine form. Recent reconstructions reveal an elegant, long-winged toothed bird that probably dipped after surface prey as it flew close to the surface of the sea (Clarke 2004).

### Neornithes: Modern Birds

Of the modern bird orders, the ratites and tinamous, also called 'palaeognaths', are regarded as the most basal divergence (Dyke & van Tuinen 2004). However, evidence suggests that their age as a group is comparable to that of many groups of so-called 'neognathous' birds, which makes unravelling their history complicated. The most ancient palaeognaths come from at least the early Paleogene of North America and Europe, in the form of the Lithornithidae (Houde 1988). The fossil evidence to date suggests that palaeognaths originated in the Northern Hemisphere and is thus in contrast to evidence from the modern distribution of the ratites and tinamous, and also *contra* molecular studies (e.g. Cooper *et al.* 2001). When the genomes of two species of moa are included, the origins of the ratites are pushed back into the Cretaceous. The fossil Lithornithidae are an enigmatic group whose relationship to the other palaeognaths is poorly known, although they may have been related to the ancestor of the modern ratites (Dyke & van Tuinen 2004). The Lithornithidae *sensu* Houde (1988) is divided into two grades (see also Davies 2002). One, the *Lithornis-Pseudocrypturus* grade, consists of *Pseudocrypturus cercanaxius* from the Middle Eocene of Wyoming and six species of *Lithornis* from the Eocene of Europe (exemplified by *L. vulturinus*) and the Paleocene and Eocene of North America (e.g. *L. promiscuus*). Specimens have also been found in rocks of putative Late Cretaceous age from New Jersey, USA (Parris & Hope 2002), pushing the origin of this family back into the Cretaceous. These birds were superficially tinamou-like, but they differed in many ways, having a moderately long, sensitive bill and relatively long legs with four toes, the hallux (or 'hind toe') being well developed and adapted for perching. They also possessed an unreduced keel, indicating that they were capable of sustained flight, unlike any modern palaeognath. The second grade consists only of *Paracathartes howardae*, a much larger bird, more heavily set, and evidently a poor flier, adapted for a more cursorial way of living, and possessing a reduced hallux. Recent work on the lithornithids has confirmed their status as palaeognaths through observations on their eggshells (Grellet-Tinner & Dyke 2005), whilst new discoveries indicate that lithornithids are closely related to tinamous, rather than their similarity being purely a consequence of similar lifestyle (Leonard *et al.* 2005). The Lithornithidae died out by the Middle Eocene, when the only palaeognath present was the European *Palaeotis weigelti* (family Palaeotidae), a more advanced species related to extant forms such as the ostriches (Houde & Haubold 1987), if not to all modern ratites (Dyke & van Tuinen 2004). Like the modern species, *Palaeotis* was flightless, had long legs and lacked a hallux, consistent with a cursorial way-of-life. It also possessed a narrow bill, similar to that of a cassowary. *Palaeotis* was similar in size to a small modern crane (Olson 1985). Originally described as a bustard, *Palaeotis* was later redescribed as an ostrich, when it raised the possibility that the ratites were, in fact, offshoots of some neognathine lineage, with their resultant primitive states being the result of extreme neotony (retention of juvenile features into adulthood). Even the palaeognathous palate has been

---

Unassigned Neornithines  
22–23 species are unassigned even to order.

---

Palaeognaths  
62 fossil species, 35–36 genera

Although the Lithornithidae had an appearance reminiscent of the Neotropical tinamous, they differed in a number of ways, most notably in the their perching foot and the ability to perform sustained flight. *Pseudocrypturus cercanaxius* was found in Middle Eocene deposits of Wyoming, USA. A putative *Pseudocrypturus* has also been suggested from Europe (Houde 1988).

suggested to be a result of neotony. However, the discovery of the lithornithids and a reanalysis through morphological and molecular studies have revealed no relationship with modern neognathous birds.

Combined fossil and Molecular studies suggest that the oldest 'modern' group of ratites are the rheas of South America (Cooper *et al.* 2001), with the moas of New Zealand being the next offshoot. However, other studies differ: in those that incorporate molecular and fossil work, the old associations reappear, although in a different ordering, with the ostrich/rhea partnership being the most recent split, the kiwi/moa partnership the oldest, and the cassowary/emu partnership splitting off somewhere in-between. In this scenario, *Palaeotis* evolved from the ancestor of all modern ratites (as per Dyke & van Tuinen 2004), and is not directly related to the ostriches, while the lithornithids would be ancestral to all of the above, with the tinamous being the most ancient group. This last is at odds with the fossil evidence for tinamous alone, as the oldest species found are Miocene in age (Bertelli & Chiappe 2005). The one drawback with the second molecular study is that the associated details that would allow us to see if this was a better phylogeny have not been published as yet, while arguments as to why the study differs from that of Cooper *et al.* (2001) have not been put forward. These are only two examples of the arguments currently raging over the origin of ratites, but what these studies have done is instigate debates about the need to link known fossils into molecular calibrations. Obviously, they have also highlighted the problems of ratite biogeography. If the ratites are of northern origin, as the discovery of *Palaeotis* suggests, why are all modern ratites found on the remnants of Gondwana, with no relatives in Europe today? Conversely, if the ratites are of southern origin, as the molecular information suggests and which seems to be the more plausible explanation, where are the Gondwanan fossils? There is still a huge gap in the fossil record with respect to early Tertiary ratites. At least one of the mysteries in ratite evolution has been resolved recently, namely the origins of the two-toed ostriches of the genus *Struthio*. For a long while, the only early *Struthio* fossils known came from the Miocene of Moldavia, in the form of *S. orlovi* (see Feduccia 1996), while there was an extensive record of ostriches from the Pliocene and Pleistocene of Europe and Asia, including the widespread *Struthio asiaticus*, the European *S. brachydactylus* (which may also have existed in the Late Miocene), and the giant Georgian *S. dmanisensis* from the Early Pleistocene. At the same time, only thickset, graviportal ostriches (originally thought to belong to the Aepyornithidae), such as *Diamantornis*, were found in African deposits. It was theorised that *Struthio* had evolved in the grasslands of Asia and Europe, and that it was only later that it spread into Africa, when the graviportal species disappeared. Then, in the 1990s, a Lower Miocene ostrich, *S. coppensi*, was described from Namibia (Mourer-Chauviré *et al.* 1996), while a biostratigraphic series from the early Neogene was described from the same area, showing changes in egg type from 'aepyornithoid' (i.e. *Diamantornis*) to 'struthioid' (i.e. *Struthio*). Thus, one graviportal ostrich at least was the direct ancestor of a modern *Struthio* (Senut *et al.* 1998). These discoveries have turned the older theories on their head, for now it is possible to state that the gracile, two-toed ostriches did originate in Africa, migrating out into Eurasia in the Late Miocene to take advantage of the spreading grasslands that subsequently dominated through the Pliocene and Early Pleistocene. The early fossil record of the other living ratites is not as full. Only the rheas have a fairly substantial record, mainly of Pliocene forms such as *Hinasuri nehuensis* and Pleistocene representatives such as *Heterorhea dabbeni* (Tambussi 1995). Possibly related to these are the Opisthodactylidae from the Upper Paleocene to Miocene, members of which include *Diogenornis fragilis* from southern Brazil and *Opisthodactylus patagonicus* from Argentina, but the fossils of many of these are rather fragmentary. All rheas are South American, so it is reasonable to assume that they originated there, rather than evolving elsewhere then migrating into South America. Likewise, the cassowaries and emus originated from within the range they occupy now, in Australia. However, they have a very limited fossil record, with a pygmy cassowary, *Casuarius lydekkeri*, from the Pleistocene of New Guinea and a number of emus from Australia (Vickers-Rich *et al.* 1988). The emus are of particular interest, as there exist two species that share characters of both the forest (cassowary) form and the bush (emu) form, namely *Emuarius gidju* and *E. guljaruba*, from the Oligocene. These are probably close to the basal stem lineage before the cassowaries and emus split and adapted to different habitat types (Boles 1992, 2005a; see also Feduccia 1996).

Three modern ratite families are now extinct, namely the Aepyornithidae and the two families within the order Dinornithiformes. The elephantbirds (Aepyornithidae) were formerly thought to share a close relationship with the ostriches (see Feduccia 1996), but molecular techniques have pointed at a more derived ancestry with the kiwis, cassowaries and emus, and that the graviportal ostriches of Africa were probably not of this family, the Aepyornithidae being endemic to Madagascar (see Davies

2002). The family consisted of seven species in two genera: three species in *Mullerornis*, which died out during the Pleistocene, and the four larger species in *Aepyornis*, ranging from the Pliocene to early Holocene. These were heavy-bodied birds, but only one reached elephantine proportions, namely *A. maximus*, the Vouronsatrana (Marden 1967), standing at 2.7–3 m and estimated at 418–457 kg (Amadon 1947), making it the heaviest bird known: the largest extant ratite by comparison, the Ostrich (*Struthio camelus*) weighs a mere 100–135 kg. Like all the larger ratites, the aepyornithids were herbivorous browsers (Wetmore 1967); the giant size of the largest may have allowed it to graze the higher branches of bushes and small trees, out of reach of its smaller relatives. The last of the aepyornithids, *A. maximus* itself, disappeared at a time coincident with human arrival on the island, eventually becoming extinct by the end of the 16th century. It seems that human overexploitation of the environment caused its downfall, rather than direct persecution (Burney 1993, Burney *et al.* 2003).

The speciose moas of New Zealand also succumbed to human colonisation, but in their case it was a combination of Maori hunting pressure and loss of habitat that wiped out most of the species by the 14th century (Holdaway 1989, Huynen *et al.* 2003, Worthy & Holdaway 2002). One species, *Megalapteryx didinus*, may have survived just long enough to be seen by the first European settlers. However, doubt has been cast on the reliability of these sightings, while archaeological evidence associated with Holocene moa bones indicate that moas were wiped out long before the European colonisation (Anderson 1989). The plethora of moa bones and the presence of mummies has meant that the Dinornithiformes have been extensively studied and written about, both in terms of their evolutionary history and ecology (see Worthy & Holdaway 2002). Although the oldest known moa fossils date to only 2.5 million years ago (mya), at the end of the Late Pliocene (Worthy *et al.* 1991), their DNA indicates that these flightless giants diverged from the other 'modern' lineages more than 80 mya, in the Late Cretaceous (Cooper *et al.* 2001). These studies also suggest that ratites invaded New Zealand on two different occasions, rather than the moas and Kiwis sharing a common ancestor. The 10–11 species of moas are divided into two families: Emeidae (synonym: Anomalopterygidae), consisting of the majority of species, generally robust in form; and Dinornithidae, containing only the two species of tall moas, exemplified by the North Island *Dinornis novaezealandiae*, (which includes *D. giganteus*). The two families split from each other about 18 mya, when much of New Zealand became submerged, while the major diversification of species occurred about 4–10 mya, when New Zealand was experiencing major geological upheavals in combination with climatic cooling (Baker *et al.* 2005). Both moa groups are characterised by a great variation in size within the species, which has been attributed to reversed sexual dimorphism, for example in *Pachyornis*, *Emeus* and *Megalapteryx* (Worthy 1987, 1988), culminating in a recent combination of morphological and molecular analyses which have shown that, in *Dinornis* at least, the females were as much as twice the size of the males (Bunce *et al.* 2003). This has led to immense confusion over the number of species in the past, with up to 38 being recognised, a problem confounded by the lack of understanding that moas had a slow growth rate when compared to other birds (Turvey *et al.* 2005). Despite their ancient demise, moa signs can still be seen in New Zealand today, from (probable) ancient trackways (Horn 1989) to the better substantiated effects of these herbivorous birds on the evolution and ecology of many of New Zealand's native plants (see, e.g., Bond *et al.* 2004, Greenwood & Atkinson 1977). The picture emerging is one of differing habitat and feeding preferences, with some species, such as *Dinornis robustus* and *Pachyornis mappini*, being widespread in a variety of habitats, the former primarily feeding on coarse twigs and fibrous shoots, the latter on tough leaves, while others, such as *Anomalopteryx didiformis* (another specialist of tough leaves) and *D. novaezealandiae*, were species dominating in the more heavily forested regions. Some, for instance *Megalapteryx didinus*, foraged along upland forest edges as well as in high-altitude grasslands (Worthy 2002). Finally, *Euryapteryx* and *Emeus* contained shrubland species that fed primarily on soft leaves and berries.

Whilst the evolution of the ratites is tied up with the land, that of the next few groups is linked with water, in particular the sea. The 'seabird' morphology has occurred several times in the fossil record. We have already seen this in the toothed birds, where there are long-distance fliers, such as the enantiorn *Halimornis*, and diver (= gaviiform) types, such as *Hesperornis*, *Baptornis* and relatives. Even the gull morph has occurred several times, first in such toothed birds as *Ichthyornis* and later with the true gulls and within the Pelecaniformes. In addition, several seabird species, ancient and modern, have evolved heightened swimming skills at the cost of flight, itself an energy-costly form of locomotion. The most famous of this last group are probably the penguins. Today there are about 20 living species, but over 50 additional species are found in the fossil record, with many coming from South America and Antarctica,

Females of the *Dinornis* moas were almost twice the size of the males: sexual dimorphism in the other moa species was not so extreme. Compared to other ratites, the dinornithid moas were huge, only exceeded by members of the Aepyornithidae. Current opinion is that there were only two species of Holocene dinornithid, *D. novaezealandiae* (shown here), on the North Island, and *D. robustus*, the South Island equivalent.

---

*Sphenisciformes* (penguins)  
52–55 fossil species, 33–35 genera

The Plotopterids, like this Japanese species, *Copepteryx titan*, were large cormorant-like birds related to boobies and gannets. Flightless, they possessed a feature that today is only seen in the penguins (*Sphenisciformes*): an advanced flipper-like wing. Inhabiting the north Bering Sea, these large birds appear to have been the ecological equivalent of the Southern Ocean penguins. Indeed, one authority (Mayr 2005d) has even pointed at a possible sister-relationship between the two groups.

Gaviiformes (divers)  
16–18 fossil species, 5–7 genera

the majority originating from the early Tertiary. The oldest-named species, *Waimanu manneringi*, comes from the late Early Paleocene of New Zealand (Slack *et al.* 2006). At an estimated height of 80 cm, this species was about the size of a Yellow-eyed Penguin (*Megadyptes antipodes*). However, unlike that species, but like other ancient penguins, *Waimanu* possessed an elongate skull and bill. Other ancient penguins are renowned for their large size. The Late Paleocene *Crossvalia unienwillia*, for instance, was a penguin 1.4 m tall from Seymour Island (Tambussi *et al.* 2005), a place that has revealed 28% of the known fossil penguin species. The largest species, however, must be *Anthropornis nordenskjöldi*, from the Late Eocene of Seymour Island, and *Pachydyptes ponderosus* a Late Eocene New Zealand penguin. George Gaylord Simpson (1946) estimated that these birds had a maximum standing height of 5'4" (1.6 m), although he admitted that there was a large degree of error involved in the sorts of estimates undertaken. These early penguins were similar in general appearance to modern species, and some species were already highly colonial, like their modern counterparts. Penguin relationships to other birds are, however, still ambiguous, with suggested connections with the tubenoses (*Procellariiformes*), through similarities of fledgling nasal morphology combined with other osteological features. More recently, G. Mayr (2005d) has suggested a possible close relationship between the penguins and an extinct group of cormorant-gannet relatives, the Plotopteridae, an amazing northern Pacific family of large to gigantic seabirds that, although cormorant-like in many respects, bore flipper-like wings similar to those of the penguins and which have been considered ecological equivalents since their discovery. The first species to be described was the Early Miocene *Plotopterus joaquinensis* of California, the coracoid of which Hildegard Howard (1969) recognised as coming from an as yet undescribed form that 'flew' through the water. However, she could not state emphatically that the birds were flightless, although she did infer it. She estimated the size of the bird, likening it to Brandt's Cormorant (*Phalacrocorax penicillatus*). Several more fossils have subsequently been described from sites in Japan (Olson & Hasegawa 1979), including the largest species, the Late Oligocene *Copepteryx titan*, estimated at 1.8 m in total length. However, the earliest species, *Phocavis maritima*, was found by Goedert (1988) in Late Eocene deposits in Oregon. The demise of the group in the Early Miocene has been attributed to the rise of the sea mammals, the proliferation of which may also have caused the extinction of the giant penguins in the Southern Hemisphere (Simpson 1971). However, rising sea temperatures may also have contributed to the extinction of these giant diving birds (Goedert 1988).

The divers have also been suggested as the northern sister-group to the penguins through similarities in the bill morphology of some fossil penguins. However, like other groups, there are no intermediate forms that would suggest such a relationship. A substantial number of Gaviiformes have been recorded from the Miocene and Pliocene of Europe and North America. Many of these are currently placed in the genus *Gavia*, but Mayr (2004e) states that some of these birds are 'clearly stem group representatives of the Gaviidae'. The marine *Colymboides* are the earliest definitive divers, with a range extending from the Eocene to the Early Miocene. They include the teal-sized *C. minutus* from the Late Oligocene/Early Miocene of France. Although these birds were recognisably divers, their leg morphology was less adapted to foot-propelled swimming than modern species. Indeed, R. W. Storer, who studied *C. minutus* in 1956, pointed out that the differences observed between *Colymboides* and *Gavia* have a lot to do with the smaller size of *Colymboides* and its lesser degree of specialisation. Even so, a species found in Germany, *C. metzleri*, has revealed that even this primitive marine genus specialised on a diet of fish. Two putative divers, *Neogaeornis* and *Polarornis*, are of particular interest as they come from Upper Cretaceous deposits in Chile and Antarctica respectively (Chatterjee 2002, Olson 1992a); they may even be the same species (Mayr 2004e). The former consists of a single tarsometatarsus, while the remains of *Polarornis* are more extensive. However, even here, the reconstruction of much of the fossil has been questioned, whilst five of the six characters used to assign it to within the Neornithes are also found in more primitive Mesozoic birds. The relationship of *Polarornis* and *Neogaeornis* with the Neornithes, let alone the Gaviidae, is therefore still debatable and awaits further analysis, particularly given their physical location well outside the distribution of all other known divers.

The next group in traditional classifications, the boobies, cormorants and darters, have a strong fossil record, with a total of about 80 species, examples coming from all continents except Antarctica. Of the three groups today, only the darters are primarily freshwater, and while the cormorants have freshwater examples, the boobies are exclusively marine. Although the similarity in habitat type is true for the fossil record for two of these families, the earliest species of sulid, *Masillastega rectirostris*, from the Middle Eocene of Messel, Germany, was at least partially freshwater. If this is indeed a sulid, it would be the only member of the family known from freshwater deposits

Pelecaniformes and Odontopterygiformes  
125–129 fossil species, 46 genera,  
12 named families

(Mayr 2002d). Known from a single skull, *Masillastega* possessed a longer bill in relation to other features than its modern counterparts; this is probably due to the specialization of modern species to the plunge-diving technique so characteristic of the Sulidae. The next oldest is *Sula ronsoni*, from the Early Oligocene of France, some 15 million years later, but this is a marine species, more typical of the family. The identity of other species in the family is not so controversial, yet they still reveal interesting facts. One is that the north Pacific had its own group of gannets (as opposed to boobies), although that lineage ended with the Californian *Morus reyanus* in the Late Pleistocene (see Olson 1985). The majority of fossil sulids come from the USA and Europe, although a few, for instance *Ramphastosula ramirezi*, have been discovered elsewhere (in this case, Peru). The discovery of cormorant fossils has also shown a concentration of specimens, and therefore species, in Europe and North America, although species have also been found in Africa, South-east Asia and Australia. The Phalacrocoracidae are remarkable in their overall similarity to each other, and such authorities as Feduccia have noted the lack of morphological diversity within the family, with the only bizarre species being the modern Galapagos Flightless Cormorant (*Phalacrocorax harrisi*)! The fossil darters are more interesting. The earliest purported species is *Protoplotus beauforti*, from the Eocene of Sumatra: this was a small bird, but already with the slender darter-like bill (Lambrecht, cited in Martin & Mengel 1975). However, it differed from modern anhingas in its limb proportions and small size, which contribute to its position outside of what we would term an 'anhinga' (Vickers-Rich, cited in Olson 1985) and has led to it being assigned its own family, Protoplotidae (van Tets *et al.* 1989). The next oldest, 'true' darters are *Anhinga subvolans* and *Meganhinga chilensis*, from the Early Miocene of Florida and Chile respectively. *A. subvolans* was originally described as a cormorant (Brodkorb 1956), but the condition of the humerus was noted as being similar to that of the darters, a group that tend to soar more than the cormorants (Becker 1986a). *M. chilensis*, on the other hand, was a flightless, giant species, like many of the Miocene anhingas from the Americas, which have also been placed in genera other than *Anhinga* by Noriega and his colleagues in papers from 1992 to 2004 (e.g. Noriega 1992, 2001, Noriega & Alvarenga 2002, Noriega & Piña 2004, Rinderknecht & Noriega 2002). The largest darter found to date is *Macranhinga paranensis*, another Upper Miocene species, this time from Argentina. Weighing an estimated 5.4 kg, it was almost four times the size of the modern American Anhinga (*A. anhinga*). Intriguingly, *M. paranensis* is thought to have hunted using a pursuit-diving technique like that of cormorants, rather than the more typical stalking style of other darters, while it also converged on the cormorants in terms of its flapping flight (Noriega 2001). It should be pointed out that whilst the anhingas listed here are all South American, fossil species are also known from North America, Africa and Australia.

There are a number of other small families within the Pelecaniformes *sensu lato* that deserve some mention. More recent cladistic analyses indicate that their placement within the order is purely through overall similarity of form, rather than any true phylogenetic relationship. This is complicated by the lack of early fossils, so that we are still in the dark as to what the 'proto-sulid' or 'proto-pelican' looked like. What we do find, though, are some tantalizing windows into an alternate world, where freshwater gannets lived, and where brackish-water, gull-like frigatebirds foraged on lakes in North America. One such frigatebird was the North American *Limnofregata azygosternon*, which fed on the fish of deep lakes in what is now Wyoming (Olson 1977). It is proposed that, like gulls today, an assemblage of different species of *Limnofregata* existed, taking advantage of the huge numbers of fish in this giant lake system (Olson & Matsuoka 2005). To date, we only know of two species in this genus, the afore-mentioned, short-billed *L. azygosternon* and the larger, longer-beaked, *L. hasegawai*, both of which are Lower Eocene in age. Their wings were not as long as modern species and, although these birds possessed reduced feet, they were not as small as in modern frigatebirds. Also unlike the marine frigatebirds, the toes were long and well-developed, indicating that *Limnofregata* was able to paddle, probably scavenging fish from the lake surface as many gulls do today. Several factors have been put forward for the extinction of these inland frigatebirds. One is the cooling of the climate that occurred in the early Middle Eocene, another, the infilling and desiccation of the Green River lakes, while the arrival of potential competitors such as the gulls may have been the final element that pushed frigatebirds into the pelagic niche that they occupy now. As old as the frigatebirds are the tropicbirds, constituting the families Prophaethontidae and Phaethontidae. For a long while, the only fossil species known was the Lower Eocene *Prophaethon shrubsolei*, first identified in the late 19th century from southern England, and reappraised by Harrison & Walker in 1976, when it was identified as a new family. Very recently, a new, Paleocene, species has been discovered, therefore older than *Prophaethon*, but equating to the age of other

*Osteodontornis orri* is a member of a group of birds (Odontopterygiformes or Pelagornithidae), the like of which has no counterpart today. At one time, representatives could be found over the seas as far apart as Europe, South America and the Australian Antarctic. These were generally huge birds, with long albatross-like wings, but their main feature was the large bill with its bony 'teeth', probably used to sweep up squid and similar animals from the surface of the world's oceans.

Procellariiformes  
49–51 fossil species, 17–19 genera

tentative prophaethontid fossils found in North America. This new species, *Lithoptila abdounensis*, extends the fossil family biogeographically, as it was found in phosphatic deposits of the Ulen Abdou basin in Morocco; it is also the earliest African neornithine bird fossil discovered to date (Bourdon *et al.* 2005). Other tropicbirds, of the Phaethontidae, are putatively identified from Miocene deposits on both sides of the Atlantic. Although tropicbirds have a similar overall appearance to gannets, this may be purely a result of the plunge-diving technique that these birds specialise in, for the studies of Bourdon and her colleagues point to a relationship between the phaethontid lineages and the Procellariiformes, not the Pelecaniformes—something that has been suggested by a number of other studies. If the recent molecular analyses are correct, then even the pelicans do not belong with this grouping, being the most derived family within a lineage that includes the Shoebill and Hamerkop, usually considered Ciconiiformes (see van Tuinen *et al.* 2001). While there is some evidence for this in the osteology of modern species, the fossil representatives of these other families are too similar to modern forms to shed light on the relationships between the three groups. The fossil record of the pelicans themselves reveals a number of small species from the Tertiary, and several species from the Miocene and Pliocene: the Pelecanidae were widespread early in their fossil history.

Often portrayed as pelican-like, but in reality the most unusual group associated with the Pelecaniformes, is an extinct lineage known as the 'pseudodontorns', a name given to them because of the bony, tooth-like projections along the cutting edges of their immense mandibles (Feduccia 1996). These were giants among the seabirds, yet they were incredibly light, with elongate bones and wings specialised for gliding. For instance, *Osteodontornis orri*, from Late Oligocene and Miocene water off California, had a wingspan of 5.5–6 m (Olson 1985), whilst the smallest species were about the same size as modern albatrosses. This may not be a coincidence, for Olson suggests that, like extant albatrosses, pseudodontorns were probably pelagic species. According to Zusi & Warheit (1992), these gigantic gliding birds fed by taking prey on or from just below the surface whilst they were in flight, using a downward nod of the head, similar to the surface-plucking behaviour of frigatebirds, or sitting on the surface, using a lunging behaviour that can be seen in modern pelicans: the tooth-pegs on the bill may have enabled the birds to hold on to soft-bodied prey such as squid. The pseudodontorns first appear in the fossil record with *Pseudodontornis tenuirostris* from Late Paleocene deposits in the British Isles and *Odontopteryx* species from the Late Paleocene/Early Eocene of Morocco. The first Pacific records come from Middle Eocene deposits in Washington State (Bourdon 2005, Warheit 2002). These birds spread throughout the Atlantic and Pacific oceans very early in their history, and were found as far south as Antarctica. Their reign lasted 57–59 million years, with the last representatives of the group, members of the genus *Pelagornis*, coming from the Pliocene. Like the Pelecaniformes in general, there is a lot of controversy over the phylogeny of the pseudodontorns. They have been assigned to a separate order, the Odontopterygiformes, with an association with the Procellariiformes and Pelecaniformes, or as a separate suborder (Odontopterygia) within the Pelecaniformes itself. Within the latter, most recent authors list the species under one family, the Pelagornithidae, but with the proviso that the exact relationship to other Pelecaniformes is uncertain. Given that the Pelecaniformes are now generally regarded as being polyphyletic, it is perhaps no surprise to find other proposals have been put forward. The most recent cladistic analysis, for example, suggests that the pseudodontorns (as the order Odontopterygiformes) are the sister-taxon to the Anseriformes (Bourdon 2005). However, there are some problems with this study, as other anseriform relatives such as the gastornithids were not included in the analysis, which might have clarified the degree of this relationship.

The earliest fossils of the Procellariiformes come from the Cretaceous and Paleocene, but most are too fragmentary for proper identification, and thus are deemed unassignable (Dyke & van Tuinen, 2005). An isolated humerus from New Jersey Greensand deposits (Lower Paleocene) was listed as *Tyttostonyx glauconiticus*, and is regarded as *incertae sedis* by Kenneth Warheit (2002), although assigned to the family Tyttostonychidae and tentatively placed in the Procellariiformes by Olson & Parris (1987). The earliest definable procellariiform species in Europe are members of the Diomediodidae, reported from the Lower Oligocene of Germany, France & Belgium, as well as from Iran (Mayr *et al.* 2002, Peters & Hamedani 2000). However, it is not known to which of the extant groups they were most closely related. Beautifully preserved specimens of *Diomedoides brodkorbi* (Germany, Early Oligocene) show a peculiar foot morphology most similar to the modern storm-petrel, *Nesofregata*. Although twice the size of the latter, these birds may have shared similar feeding habits, flying into the wind and trailing their feet in the water as they searched for surface prey. All other tubenose fossils belong to extant families, some of which fill anomalies in their distribution. The Diomedidae, for example, are absent today from the

north Atlantic. However, at least five species existed there in the Pliocene, including *Phoebastria/Diomedea anglica*, also found in the Pacific, and *P. rexsularum*, endemic to the north Atlantic (Olson & Rasmussen 2001). A species known as *P. howardae* was also described, but this has since been synonymised with the Short-tailed Albatross (*Phoebastria/Diomedea albatrus*), and accounts for one of three modern species whose ranges extended into the north Atlantic. Bermuda records of this species are particularly interesting as they show a healthy colony existed until the Middle Pleistocene, when a momentary 20 m rise in sea level caused its extinction (Olson & Hearty 2003), thus removing albatrosses from the north Atlantic avifauna. The Procellariidae are the most speciose fossil-wise of the other tubenoses. The coast of Miocene California has been particularly fruitful in searching for procellariiform fossils, and several species of the modern genus *Puffinus* have been uncovered, while the genus *Fulmarus* was also more speciose during this period than it is now. Like fossil members of the Hydrobatidae and Pelecanoididae, these birds are generally indistinguishable from modern genera even if, at the species level, they can be separated.

The long-legged waders are usually the next group in traditional classifications. However, special mention should be made of one group that is usually placed alongside the divers and penguins at the beginning of traditional classifications, namely the grebes, primarily because recent molecular and morphological studies suggest that they are closest to the flamingos and relatives (Mayr 2004f, Manegold 2006, van Tuinen *et al.* 2001), a group traditionally associated loosely with the Ciconiiformes. The grebes have a poor fossil record that sheds little light on any relationship. The earliest described species is *Miobaptus walteri*, from the Early Miocene of Czechoslovakia (Švec 1984), but this is already a typical grebe, as are the several species of *Podiceps* and *Aechmophorus* from the North American Pliocene. If correct, and given the fact that even flamingos swim on occasion, and that their closest fossil relatives, the Palaelodidae, were better adapted to swimming, it is suggested that the ancestor of the Phoenicopteriformes + Podicipediformes was aquatic, rather than a wader. However, the earliest members of the flamingo group, *Juncitarsus gracillimus*, from the Eocene of North America and the contemporaneous *J. merkei* of Europe, were small, colonial, wader-like birds inhabiting saline environments (Feduccia 1996). Mayr suggests that further study may reveal the juncitarsids to be the sister-group to the flamingos + grebes, rather than being ancestral, if they are closely related to these two groups at all. The next oldest in terms of fossils are the Phoenicopteridae, with representatives in the Early Oligocene of France. The most surprising discovery, however, is the existence of several species in Australia, as well as a species of *Phoeniconaias* (*P. siamensis*) from the Miocene of Thailand. An Australian species which also belongs in this genus, *P. gracilis*, lived in the Lake Eyre region in the Early Pleistocene, and is the youngest flamingo known from that continent. Another Australian flamingo, the Late Oligocene/Early Miocene *Phoenicopterus novaehollandiae*, was a member of the most widespread genus today. *Phoenicopterus*, is the most speciose genus in the family generally, including several fossil representatives in the New World. Flamingos can be recognised by their extraordinary long legs and neck combined with a deeply decurved bill specially adapted to filter-feeding. In contrast, the closely-related Palaelodidae possessed a short, straight bill. Like the Phoenicopteridae, they were probably planktivores, but had a more primitive morphology. In some areas, the palaelodids were extremely common and, like the Phoenicopteridae, were highly colonial. For instance, at least 477 individuals of *Palaelodus ambiguus* have been recovered from the Miocene deposits of St Gerand-le-Puy, France, along with large numbers of bones of three other species (see Feduccia 1996). Also like the Phoenicopteridae, the Palaelodidae have been found in Australia (*P. kadimakari*), in Europe and in North America, where the second genus in the family, *Megapalaelodus*, also existed.

The other long-legged waders are collected in the order Ciconiiformes. The most distinctive are probably the herons, the earliest fossils of which are already characteristically ardeid; these are *Proardea amissa* from the Upper Oligocene of Europe (Mayr 2005a), and *Calcardea juniei* from Eocene deposits in North America. Two other families, described as 'aberrant African forms' by Feduccia (1996), the Hamerkop (Scopidae) and the Shoebill (Balaenicipitidae), may actually be close relatives to the pelicans (Mayr 2003c, van Tuinen *et al.* 2001), rather than having a close relationship with other Ciconiiformes (*contra* Feduccia 1977). The fossil record of these two families lends nothing to the debate: that of Balaenicipitidae is too fragmentary, although one species, *Paludavis richae*, does extend the family's range into the Oriental region (Harrison & Walker 1982); that of Scopidae consists of one Early Pliocene species from South Africa, *Scopus xenopus*, 'slightly larger than the living species' (Feduccia 1996). Within traditional classifications, it is the Ciconiidae that are regarded as the closest relatives of the Shoebill, while the Hamerkop is of unknown relationships.

---

#### Podicipediformes

17 fossil species, 7 genera

---

#### Phoenicopteriformes

34–35 fossil species, 12 genera

Flamingos have undergone radiations of two rather different body forms. One group, the Phoenicopteridae, exhibits long legs and neck combined with a highly modified, bent bill containing a specialised sieving mechanism. The other group, the Palaelodidae, had a straighter bill and were better adapted to swimming, although they still had a comparatively long neck. Several species are known, from different continents. The discovery of bone beds of the European *Palaelodus ambiguus* shows another side to the palaelodids: like their extant cousins, they appear to have been highly colonial birds, probably often mixing with other members of the Phoenicopteriformes at particular sites.

## Ciconiiformes

72–75 fossil species, 59–60 genera

Originally misidentified as a shorebird, *Rhynchaetites messelensis* is now regarded as the oldest substantiated fossil ibis, with several specimens known from the Middle Eocene of Messel. It differed from modern species in many ways, including the morphology of the chest bones and its very short tarsometatarsi, as well as its very small size.

## Anseriformes and relatives

187–195 fossil species, 78–80 genera

The Hawaiian Islands were at one time home to ducks that had evolved into giant, flightless, goose-like birds. The most widespread of these 'moa-nalo' was *Thambetochen chauliodous*. There is evidence that these birds occupied a specialised browsing niche, indicated by the unusual morphology of the jaws, in that they had bony pseudo-teeth and modifications to the head and neck (Olson & James 1991).

The storks themselves are also suggested to be derived relatives of the cathartid vultures. The earliest species of stork known to date, *Palaeoephippiorhynchus dietrichi*, comes from the Late Eocene to Late Oligocene deposits of the Fayum series of Egypt (Boles 2005b, Feduccia 1996, Mayr 2005a); the exact age of this species appears to be contentious. Likewise, the Middle Eocene Chinese 'stork', *Eociconia sangequanensis* (Hou 1989), needs confirmation before it can be claimed as the earliest ciconiid (Unwin 1993), while a number of other potential 'storks' are too fragmentary to be identified properly. Of the later species, *Leptoptilus falconeri* is of particular interest, as the distribution of this giant marabou stretched across north Africa, Eurasia and into India. At 2 m in height and weighing an estimated 20 kg, this was one of the largest of the storks. Being predominantly terrestrial, *L. falconeri* probably had slightly reduced forelimbs, leading to a marginal reduction in flight ability (Louchart, Vignaud *et al.* 2005). Another giant stork, originally described as a *Mycteria*, is *Ciconia maltha*, a North American species from the Upper Pliocene and Pleistocene that possessed a large size range, from smaller than the wood-stork to larger than the Jabiru (Miller 1932). Fossil ibises are equally spectacular, with those of particular interest originating from the extremes of the fossil and subfossil record. The earliest identifiable ibis, the German *Rhynchaetites messelensis*, is also the smallest member of the family. This species is famous for its short metatarsus, which it shares with another, as yet, undescribed species from France (Mayr 2005a). At the other end of the timeline are a number of insular flightless species, with *Xenicibis xympithecus* from Jamaica (Olson & Steadman 1977) and two species of *Apteribis* (*A. glenos* and *A. brevis*) from the Hawaiian Islands. These ibises had short stout legs and, when their bones were first discovered, their identity as members of the Threskiornithidae were obscured; indeed, *Xenicibis* was originally described as a relative of the sloths and anteaters, rather than a bird! When the bones of the Hawaiian species were first examined, they were said to resemble most closely kiwis: it is thought that these birds searched the leaf litter for invertebrates much in the way that kiwis do today.

Another waterbird group, Anseriformes, is one of the best represented orders in the fossil record, with nearly 200 described fossil species of ducks, swans and geese. It is also one of the most widespread orders, with examples from all over the globe and from as far back as the Cretaceous. Early species were comparatively small, duck-like animals, while later species often became gigantic and flightless, particularly island forms. The earliest representatives are clustered within the Presbyornithidae, and bear many superficial similarities with the whistling ducks. The skull of *Presbyornis* bears a close resemblance to *Stictonetta*, a basal species within the Anatidae (Olson & Feduccia 1980). Like many early groups, their relationships have come under severe scrutiny, with affiliations suggested with the flamingos, and the shorebirds and even such enigmatic groups as the Graculavidae, which led Feduccia to conclude that Early Paleocene birds all stem from a possible shorebird mosaic group with morphological similarities to a number of modern orders, be they ducks (as in the case of *Presbyornis*), ibises (for example the Messel 'rail-ibis', *Rhynchaetites*), or even flamingos (*Juncitarsus*). However, such a proposal has been rejected by many in the palaeontological and molecular communities (e.g. Dyke & van Tuinen 2004, Paton *et al.* 2002, van Tuinen *et al.* 2003), although Feduccia has since countered these arguments (Feduccia 2003a, 2003b). Even so, recent studies have moved the Presbyornithidae into the Anatoidea, as a group basal to the Anatidae (Ericson 1997), which must cast further doubt on this 'transitional shorebird' hypothesis. Presbyornithids were a widespread group, with examples from sites across the Northern Hemisphere. The most abundant fossils are of *Presbyornis pervetus*, a colonial, sexually dimorphic species from Eocene deposits of Utah and Wyoming (Ericson 2000). Another species, *P. isoni*, was a giant relative. Originally described from a single humerus from the Upper Paleocene of Maryland, it has now been found at other sites in North America and possibly also Britain (Benson 1999, Olson 1994). *Teviornis gobiensis*, another giant presbyornithid, but from Upper Cretaceous deposits in Mongolia, is also worth mentioning as it pushes the group—and, indeed, the Anatoidea generally—back before the infamous K–T boundary, thereby presenting important evidence that the Neornithes do have origins in the Mesozoic, rather than appearing after the K–T cataclysm (Kurochkin *et al.* 2002). Other ducks have been described from this period, most notably *Vegavis iaai* from the Antarctic Peninsula. However, these Cretaceous fossils are all very fragmentary, and can provide only 'tantalising indications', rather than irrefutable evidence (Clarke *et al.* 2005, Dyke & van Tuinen 2004, Noriega & Tambussi 1995).

The other notable proliferation within the fossil Anseriformes is of flightless forms. Many are island species, such as the giant swan *Cygnus falconeri*, uncovered from the European Pleistocene (Northcote 1982), but coastal examples also exist, for example the Californian 'diving goose' *Chendytes lawi* from the Late Pleistocene (Howard

1947, Miller 1925). New Zealand had a number of recently extinct anatids, many of which, again, were flightless. This avifauna included two *Cnemiornis*—giant, 1-m tall, goose-like birds—of the North (*Cnemiornis gracilis*) and South Islands (*C. calcitrans*), possibly related to shelducks, but with their modern ecological equivalent being the Cape Barren Goose (*Cereopsis novaehollandiae*) of southern Australia. However, it is the islands of Hawaii that have revealed the most bizarre forms. Here, primitive dabbling ducks (Anatinae) radiated through the early islands, evolving into large flightless, terrestrial ‘geese’ (Sorenson *et al.* 1999). Called ‘Moa Nalo’ in the native Hawaiian, these birds foraged in the forests, feeding on a variety of herbage. Four species have been described, belonging to three genera, including *Thambetochen* and *Ptaiochen*, with *T. chauliodous*, the most widespread species, from Molokai, Oahu and Maui, a related species, *T. xanion* found only on Oahu, and *P. pau* from Maui (Olson & James 1982). One species, *Chelychelynechen quassus*, had a bill particularly modified for such browsing, to the extent that it resembled more the jaws of a turtle than a duck’s bill, hence the popular name for the species, ‘Turtle-billed Moa-nalo’ (Olson & Wetmore 1976). Like 90% of the birds that were found on the Hawaiian islands, their demise occurred with colonisation by the Polynesian people. The Moa Nalo, like many island species worldwide, such as the Dodo (*Raphus cucullatus*), had no experience of such a successful terrestrial predator as *Homo sapiens*, nor of the other threats that came with him, so they had no way to cope with the onslaught; as a result, many species were wiped off the face of the earth within comparatively few years.

In 1881 a very different type of bird was described by Lemoine from Paleocene/Eocene deposits in France. Although missing much of the skeleton, he concluded that this was a huge animal, taller than a man. This he named *Gastornis parisiensis*. However, his reconstruction included a substantial amount of material that was not even avian (Martin 1992). For a long period, these birds were considered relatives of the terrorbirds—giant predatory ‘seriemas’ in the order Gruiformes from the Americas. It was not until a century after Lemoine’s description that his species and its relatives, known collectively as the Gastornithidae, were placed close to the Anseriformes (Andors 1991) and were identified as sharing a close relationship with the American *Diatryma* (Olson 1985)—so close, in fact, that the latter is now included in *Gastornis* (Buffetaut 1997). *Gastornis* (*‘Diatryma’*) *gigantea*, the most famous of the group, was a giant flightless bird, at least 2 m tall, found in North America during the Early Eocene, 58–51 mya, while its relatives lived in Europe throughout the Late Paleocene to Middle Eocene, 62–43 mya, at least. Fragmentary fossils indicate that gastornithids may have survived until about 40 mya. Examples were also present in Eocene Asia, in the form of *Zhonguanus xichuanensis* (Hou 1980), but this bird was a more primitive form to that of its larger cousins (Andors 1992). As much controversy surrounds how the birds lived as with their relationships. They were originally portrayed as terrifying giant predators that ran down and fed on the various mammals that were around during the early Tertiary. In 1991, Andors cast doubt on this long-held portrayal, pointing at the absence of a hook on the huge beak, the short toes and a physical appearance that made the animal far too heavy and large to be able to run down anything (Andors 1991, 1992)! Instead, he presented the bird as a particularly large browsing animal, feeding on bushes and shrubs in the lowlands and floodplains, comparing it in part with modern herbivorous species such as New Zealand’s surviving Takahe (*Porphyrio mantelli*), which also has a large bill. Even so, counter-arguments still exist suggesting that this was a giant predator that, although slow compared to modern predators, was still able to tackle those animals not in the prime of life through age, sickness or injury, whilst also scavenging on their remains (Witmer & Rose 1991). The same arguments also surround the mihirungs or ‘thunderbirds’ (Dromornithidae), another group of giant flightless birds rather ratite-like in form, and also now thought to be early offshoots of the Anseriformes (Murray & Megirian 1998), although their exact relationships with other basal groups, namely the Magpie-goose (*Anseranas*) and the screamers (Anhimidae), are still under question. The mihirungs occurred only in Australia, occupying a variety of niches (Murray & Vickers-Rich 2004). To date, eight species have been described, the youngest being the Pleistocene *Genyornis newtoni*, the oldest being the Late Oligocene/Early Miocene *Barawertornis tedfordi*. Trace and fragmentary fossils indicate that the dromornithids may have been around at least since the Eocene. The mihirungs included amongst their number one of the largest birds that ever lived, *Dromornis stirtoni*, standing at 3 m in height. Two species within this family are particularly interesting: one, *Genyornis newtoni*, may have come into contact with modern humans, with its extinction being connected with the spread of the aboriginal peoples through Australia. The other is the 15 million year old *Bullockornis planei*, because a lot of work has gone into examining whether this giant-billed animal fed on meat or plant material. Indeed, the latter species has been labelled in the popular press as the ‘Demon Duck of Doom’ (Pain 2000, Wroe 1999)!

The Gastornithidae and Dromornithidae were two families that contained giant, heavyweight birds with very large heads, huge beaks and powerful mandibular muscles, as seen in *Gastornis gigantea* (syn *Diatryma gigantea*), a species 2 m tall, found in the Eocene of North America (above), and *Bullockornis planei* (below), a dromornithid standing 2.5 m tall, from the Pliocene of Australia. The major authors in the field regard the Dromornithidae as being primarily herbivorous, a view that has been mirrored by studies on the gastornithids by Andors (1991, 1992).

The Du, *Sylviornis neocaledoniae*, was a giant 'megapode' from the island of New Caledonia. Described as a ratite by François Poplin in 1980, it was likened in size to a small emu, with ornamentation on its head 'like a cassowary's' (although not shown like this in the sketches of later publications). It was not till the mid-1980s that its identity as a megapode was realised (Mourer-Chauviré & Poplin 1985, Poplin & Mourer-Chauviré 1985). Its extinction is thought to have been at the hands of the human inhabitants of this island.

However, Murray and Vickers-Rich have maintained that because the mihirungs are basal anseriforms, they must have been predominantly herbivores. They argued that the mihirungs grew huge in response to the need to travel large distances between food patches. Physical evidence for their herbivory exists in the possession of large gizzard stone sets, together with, at best, a small terminal hook, both features that indicate a herbivorous, rather than carnivorous, diet (Murray & Megirian 1998). So, instead of meat, they may have fed on twigs, fibrous vegetation and hard-shelled seeds. The most unusual feature of the family are their toe claws, which have been drastically modified, becoming far more nail-like than any other bird species. These are not the raptorial claws of predators. The modification is so extreme that these 'nails' have been likened to the hooves found on cattle, with the mihirungs often being described as the only hooved birds on the planet (Vickers-Rich 1980).

There is general agreement among palaeontologists and molecular biologists that the Galliformes are the closest living relatives of the wildfowl and their kin. Like that group, the Galliformes have an extensive fossil record. The earliest examples were members of the now extinct Gallinuloididae, a group of basal 'landfowl' found across North America and Europe. Of these birds, the most intensively studied is *Gallinuloides wyomingensis*, even though it is known from only two specimens, both from the Lower Eocene deposits of the Green River Formation of Wyoming (Mayr & Weidig 2004). This was a small bird, about the size of a quail, but with relatively long legs and which probably had the appearance of a small cracid in life, as comparisons have been made in the past with that family (e.g. Olson 1985), even to the point of *Gallinuloides* being included in the family (e.g. Tordoff & Macdonald 1957). However, these characteristics are currently regarded as primitive traits in the Galliformes, rather than showing a true relationship between the two groups (Dyke 2003, Mayr 2005a, Mayr & Weidig 2004). A related species, *Paraortygoides messelensis*, has revealed two features about the gallinuloidids (Mayr 2006a): first, they are the sister-group to all other galliform birds, living and extinct; and, second, a large crop, characteristic of all other Galliformes, is absent in gallinuloidids. This latter feature—or, rather, its absence—suggests that the gallinuloidids fed only on soft plant material, rather than seeds and other coarse matter. Another basal galliform group, the Quercymegapodiidae, were also misinterpreted at one time as belonging to an extant group, in this case the primarily Australasian Megapodiidae. However, like the Gallinuloididae, the traits suggesting this relationship are now interpreted as plesiomorphic, and that there is no basis for the suggested relationship, other than that they are both galliform. Currently, members of the Quercymegapodiidae are known from Europe, from where the type genus *Quercymegapodius* was described, as well as from deposits in the Miocene of Brazil. A number of present-day groups within the Galliformes are also of interest, including some members of the more primitive groups, Cracidae and Megapodiidae. One of these is the famed Du (*Sylviornis neocaledoniae*), a flightless giant 'megapode' from New Caledonia; although usually included in Megapodiidae, it is regarded as being so aberrant as sometimes to be placed in its own family, Sylviornithidae. Reconstructions of the species show a bird almost three times the size of the modern Malleefowl (*Leipoa ocellata*) with a comb wattle on its head, the latter feature gleaned from the oral tradition of the islanders (see Feduccia 1996). This species was exterminated in the early Holocene by the first human colonists, like so many other island species in the Pacific and elsewhere. It was not the only giant megapode, as these existed elsewhere in Australasia at about the same time, with the flightless *Megavitiornis altirostris* from Fiji rivalling *Sylviornis* in size (Worthy 2000), and *Leipoa gallinacea* from Australia itself. While the story of the megapodes is one of expansion and diversification on many different islands and within Australia, that of the cracids of the Americas is one of a northerly origination, followed by a retraction, perhaps due to competition with other Galliformes, into the Neotropics. *Procrax brevipes*, for instance, was a bird from the Lower Oligocene of South Dakota (Tordoff & Macdonald 1957). The genus *Ortalis* was present in the Lower Miocene of Nebraska, through *O. tantala*, a small guan half the size of the modern species *O. vetula*; and the Middle Miocene of South Dakota, through *O. pollicaris*. Of the other Galliformes, it is perhaps surprising to discover that there was an abundance of turkey species in the past, including some tiny species. The miniature turkey *Rhegminornis calobates*, for instance, was so small that when it was discovered in Florida it was described as a jacana (Wetmore 1943a), and it was not until 1974 that its true identity as a Lower Miocene turkey was announced by Olson & Farrand. Other species within the group included members of *Proagriocharis* and *Parapavo*, as well as additional members of the two modern genera, together raising the family diversity to about 11 species. The Phasianidae and Tetraonidae also have many fossils, but these consist mainly of range extensions for genera still present today: for example, members of the genus *Gallus* have been discovered as far west as the Caucasus, in Georgia, while the genus *Pavo* had a repre-

sentative, *P. bravardi*, in the European avifauna during the Upper Pliocene (Boev 2002, Mourer-Chauviré 1989a).

Raptorial birds have evolved several times throughout the fossil record, both within the toothed birds (e.g. *Boluochia* of the Enantiornithes) and within modern birds. The most obvious of these latter groups are the so-called 'raptors', currently within the order Falconiformes. However, this grouping is artificial, forcing together two groups of birds of very different origins. That of the Accipitridae and their relatives is still ambiguous. In the case of the Cathartidae, both molecular and morphological work point to an ancestry shared with the storks (Ciconiidae), rather than falconiform raptors. The oldest fossil in the group, that of the small *Diatropornis ellioti*, comes not from the Americas, but from the Quercy Fissure deposits of France, and is Late Eocene to Early Oligocene in age (Cracraft & Vickers-Rich 1972, Mourer-Chauviré 2002). Two other species come from early in the history of the Cathartidae: one, *Phasmagyps patritus*, originates from the Early Oligocene of Colorado, and therefore comes from within the range of modern species. The other, *Oligocathartes olsoni*, is from the Lower Oligocene of England. However, Mayr (2005a) regards the latter as too fragmentary to be identifiable and perhaps this species should be removed from the Cathartidae. Although the origins of the family may not have been in the New World, or, at least, their origins may have been shared with Europe (as seems to be the case with many groups), the majority of species are from the Americas. *Hadrogyps aigialeus* represents a small stocky 'condor' from the Middle Miocene of California and was probably a coastal species (Emslie 1988), while the next 'large condor' is the Late Miocene/Early Pliocene *Perugyps diazi*, from the Pisco formation of Peru. Together, this suggests that condors evolved in North America and spread to South America by the Late Miocene (Stucchi & Emslie 2005). Cathartid vultures were at their most diverse in the Pleistocene, when several species of condor existed in North America. The formerly widespread *Gymnogyps californianus*, which we call the 'California Condor', had a range that stretched throughout the USA in the Late Pleistocene, but its range contracted with the progressive extinction of the North American megafauna (Steadman & Miller 1987). Another species, *G. kofordi*, was described from the Early Pleistocene of Florida, while a larger form of the modern species, *G. californianus amplius*, was exhumed from the La Brea tar pits, California. In addition, a closely-related condor, *G. varonai*, was found in Late Pleistocene deposits of Cuba. Alongside the Cathartidae in the Americas was another vulture-like group, the teratorns (Teratornithidae). Three of the four species were North American, the exception being *Argentavis magnificens*, whose fossil was discovered in Late Miocene deposits of Argentina, and which must have been a huge bird, with a wingspan of 6–8 m. Indeed, *A. magnificens* is considered to be the largest flying bird ever to have lived. Not only was this the largest of the teratorns, but it was also the oldest (Campbell & Tonni 1983), although it was not the first species in the family to be described. That honour goes to *Teratornis merriami*, which was also the most abundant of the group. *Teratornis* was a species whose temporal range extended from the Pliocene until the Late Pleistocene. It is probably typical of the group in many ways. Merriam's Teratorn, as it has been named, was also a large bird, but only half the size of *Argentavis*, having a wingspan of a mere 3–4 m; if one compares this with the Andean Condor (*Vultur gryphus*), which can attain a span of about 3.2 m, one can begin to see the true size of these birds. Traditionally, the teratorns have been portrayed as giant versions of the Cathartidae, even sharing their scavenging habits, a perception reinforced by the shape of the skull and by discovery of over a hundred individuals of *T. merriami* in the asphalt deposits of La Brea, a site that has produced hundreds of fossils of raptors and vultures, all thought to be attracted to the animals that became trapped there. However, instead of being scavengers, teratorns are now considered to have been active hunters, with *T. merriami* being a fish-eater and facultative scavenger (Hertel 1995). In the air, these birds may have soared like condors, but on the ground they were apparently more agile: in the smaller teratorns such as *T. merriami*, this agility may have helped them in their attempts to take off. How the giant *A. magnificens* took off is a matter for conjecture, but the age of the deposits in which it was found and the geographical position of the site indicate that its flight was enabled by the constant strong winds that crossed the South American plains in the Late Miocene, unhindered by the Andes, which were, at the time, undergoing upheaval. Another deduction from the age of this specimen is that teratorns probably evolved in South America, later spreading north into North America, before finally dying out at the end of the Pleistocene.

Just as cathartids have been found in the Paleogene deposits of Europe, so have true vultures been discovered in North America. The most diverse of these New World 'Old World' groups were the neophrons (*Neophrontops* spp.). Fossils of *Neophrontops americanus*, the first species to be described, have been found in Middle and Late Pleistocene deposits of western North America. It is one of the most recent species in

---

Cathartidae & Teratornithidae  
21–22 fossil species, 16–18 genera

---

The most famous of the fossil cathartids is the Upper Pleistocene La Brea Condor (*Breagyps clarki*). This was one of the larger members of the New World vulture guilds and may have survived into the early Holocene. It is thought that *Breagyps* represents one of the 'gulper' type vultures, and is therefore a guild equivalent to the contemporaneous California Condor (*Gymnogyps californianus*) and the unrelated African White-backed Vulture (*Gyps africanus*).

*Teratornis merriami* is the best known and commonest of the Teratornithidae. With a wingspan of 3.5–3.8 m, it dwarfed its cathartid cousins, yet was one of the smallest members of its own family. Reconstructions of teratorns have shown the birds as giant condor-like birds, because they were originally thought to be close cathartid relatives, with a similar predilection to scavenging. However, recent papers have shown that these birds—or, at least, *T. merriami*—were more likely to be predatory birds, while, phylogenetically, Campbell & Tonni (1983) point out that they might be just as closely related to storks as they are to the New World vultures. Both factors would alter the interpretative reconstruction of the teratorns, giving them a more distinctive look than has previously been portrayed.

Falconiformes (excluding  
cathartid vultures and teratorns)  
121–122 fossil species, 60–61 genera

---

the group: the oldest is probably *N. vetustus*, from the Middle Miocene of Nebraska (Wetmore 1943b), which is also the smallest. *N. americanus* is fairly typical of the American Neophrons and suggests that they were most similar to, and probably ecological equivalents of, the Egyptian Vulture (*Neophron percnopterus*), with *N. americanus* being very similar in size to the modern *Neophron*. Feduccia goes further than this, stating that the Egyptian Vulture's lack of a fossil record and the similarity between the two genera 'strongly suggests that the genus' [= *Neophron*] 'is derived from an invasion of the Old World by New World *Neophrontops* stock, possibly as late as Pleistocene time' (Feduccia 1974). While *Neophron* may be of American origin, that of the other Old World vultures can equally be American or Old World: the oldest fossils for the group include *Palaeohierax gervaisii* from the Oligocene/Early Miocene of Europe and *Palaeoborus rosatus*, from the Early Miocene of South Dakota. Apart from *Neophron* and its relatives, vultures are among the largest of the living raptors. However, there are notable examples in the fossil record of eagle-like forms of gigantic proportions, truly terrors of the air! Among these, and probably the most famous, is Haast's Eagle (*Hieraaetus moorei*) from the South Island, New Zealand (see Worthy & Holdaway 2002, for an extensive description). Until recently, the species was listed as *Harpagornis moorei*, but recent molecular research (Bunce *et al.* 2005) has shown that the closest relatives among those eagles studied were the Booted (*Hieraaetus pennatus*) and Little Eagles (*H. morphnoides*), the latter an Australo-papuan species with a wingspan of only about 1 m and a weight of 0.5–1.3 kg. *Hieraaetus moorei*, on the other hand, had a wingspan of 2–3 m, with females weighing 10–15 kg—an order of magnitude larger than extant *Hieraaetus*, and 30–40% larger than the Harpy Eagle (*Harpia harpyja*), the largest extant eagle. The main reason why this bird became so large becomes apparent when examining the ecology of prehuman New Zealand, for this was a land without any land predators and with only a few bird predators, included among diurnal species being an endemic species of harrier (*Circus eylesi*), also now extinct, a hawk and a falcon (Holdaway *et al.* 2001). Additionally, without mammalian predators, the herbivorous birds of New Zealand grew to massive proportions, most notable being the moas. Thus, the eagle's huge size was a response to a combination of competition with the resident raptors, a lack of competition with mammalian predators and the size of prey potentially available. Marks on the bones of moa up to 200 kg suggest that the eagle ambushed these large birds in forested and scrub areas, striking and gripping the moa's pelvic area, then killing with a single strike of the powerful foot to the neck or head. Giant eagle-like raptors have been found on islands elsewhere, for example *Stephanoaetus mahery* of Madagascar, which, like *H. moorei*, was present until fairly recent times, and the appropriately named *Titanohierax borraasi* of Pleistocene Cuba. In each case, it is the lack of large mammalian predators and the availability of large prey that induces the evolution of gigantism in the respective avian top predators. The fossil record reveals several other hawks and eagles, from island forms to species in genera that today are regarded as tropical or southern endemics but which were found much further north in the past, for instance, in the Americas, *Spizaetus* and *Buteogallus*. This is also the case with the secretarybirds (Sagittariidae), in which two of the three fossil species known, *Pelargopappus schlosseri* from the Middle to Late Oligocene and *P. magnus* from the Early Miocene, were found not in Africa, as one would have expected, given the distribution of the extant species, but in France, indicating the modern species to be relictual (see Mourer-Chauviré 2003 for the first African birds). Compared to *Sagittarius*, the foot bones of *Pelargopappus* were more accipitrid-like in form. Mayr (2005a) has suggested that this is because the Sagittariidae are derived from the same ancestral group as the Accipitridae, and that the accipitrid characteristics observed are due to the more primitive nature of this genus, although Mourer-Chauviré & Cheneval, 1983 had previously considered the genus to be too advanced to be the ancestor of recent Sagittariidae. The morphology of the Sagittariidae, with their long legs and eagle-like bodies and head, is fairly bizarre, even when accounting for their rather specialised hunting strategy, but it is not unique: similar morphology was exhibited by an American accipitrid, *Apatosagittarius terrenus*, the fossils of which were uncovered from the Miocene of Nebraska (Feduccia & Voorhies 1989), suggesting that this species had adopted similar hunting methods.

Unlike the accipitrids and sagittariids, the origins and diversity of the Falconidae appear to be American, with a caracara-like falcon, *Badiostes patagonicus*, known from the lower Miocene of Patagonia, while several species belonging to the modern Polyborinae and Falconinae have also been described from North America. The earliest European record is of a species of *Falco* from the Late Miocene. A close relative of the Falconidae, *Pediohierax ramenta*, is known from the Middle Miocene of Nebraska. The falcon-sized *Horusornis vianeyliaudae*, described from the Upper Eocene of the Quercy Fissure Formations of France (Mourer-Chauviré 1991) brings up an interest-

ing conundrum. Ecologically, it occupied the same niche as *Polyboroides* of Africa, *Geranospiza* of the Neotropics and *Pengana* from Tertiary deposits in Australia in that it could flex its leg backwards, thereby enabling it to 'grope around in tree cavities or hollows for nestlings or small mammals' (Feduccia 1996). From the evolutionary standpoint, its relationship to the other falconiform groups is ambiguous, as *Horusornis* shares features of its wing bones with the Accipitridae, and derived characters of its foot bones with the Accipitridae and Falconidae. These features alone would suggest that *Horusornis* is derived from the same ancestor as the Accipitridae and Falconidae. However, the distal end of its tibiotarsus bears similarities to that of owls, which clouds the issue. Such 'mosaic species' are, however, not that unusual.

The unique Hoatzin is one such species and consequently has had a chequered history with respect to studies on its phylogenetic relationships. It has been described as a primitive galliform, a member of the gruiform radiation, placed in its own order and has even been connected with the cuckoos. Recently, Hughes (2000) has suggested that the turacos (Musophagidae) should be placed alongside the Hoatzin in the order Opisthocomiformes: they are the only extant families in which the young of some species have a well-developed wing-claw. Hughes also remarked that the Lower Eocene *Foro panarium*, a ground-based bird found in Wyoming, seems to confirm this placement, as this species 'has a skull and mandible most like the Hoatzin, but shows some similarities to turacos in postcranial skeletal elements'. However, she suspected *Foro* to be a separate lineage that may stem from the same ancestor as the cuckoo and hoatzin + turaco lineages, which would agree with Olson's placement of the bird in its own family, Foratidae (Olson 1992b). True hoatzins are South American and are found much later in the fossil record, with the Miocene *Hoazinoides magdalenae* not only laying claim to being the first hoatzin fossil to be described (Miller 1953), but also representing the most westerly occurrence in the family. Unfortunately, only part of the skull was found and, although very hoatzin-like in form, little else can be told of the bird, other than that it was less specialised than the modern species.

The Gruiformes are another group in which the relationships are not at all clear. Unlike the Opisthocomiformes, their fossil record is extensive, with several families present only as fossils. The Gruiformes have their fair share of giants, with the peculiar adzebills of New Zealand, and the aptly-named terrorbirds of the Americas. Possibly unsurprisingly, there are also a large number of fossil and subfossil rails, many of which disappeared at the hands of humankind. Among the earliest of the Gruiformes are the Messel-rails (Messelornithidae), which Mayr (2004g, 2005a) regards as related to the finfoots (Heliornithidae) and rails (Rallidae). Earlier authors (e.g. Hesse 1988, Livezey 1998) included them alongside the Sunbittern (*Eurypyga helias*) of the Neotropics. The family includes four species, the earliest of which, *Messelornis russelli*, occurred in the Upper Paleocene of France (Mourier-Chauviré 1995a). The family also occurred in North America, in the form of *M. nearctica* (Hesse 1992). The most famous member of the group, described in a monograph by A. Hesse in 1988, is *M. cristata*. This bird is known from a large number of fossils, originating from various Eocene/Oligocene sites in France and Germany, including Messel itself. Some of the articulated fossils of this species include a fleshy or horny crest preserved as an impression. None of the other species have shown the possession of a crest.

The adzebills (Aptornithidae) of New Zealand are another enigmatic group, but of much more recent occurrence. In fact, these birds existed until as recently as 1000 years ago; like so many Polynesian species, they succumbed upon the arrival of humans and their animal associates (Gill & Martinson 1991). These flightless giants have been portrayed as bizarre takahe-like "rails" with large, downcurved bills and stout feet that enabled them to dig out petrel burrows, turn over litter, tear open rotting logs etc. in order to feed on large invertebrates, lizards and even tuatara and petrels (Holdaway 1989), or feed on berries, dig up tubers (Gill & Martinson 1991), or tear off pieces of tussock-grass (Feduccia 1996). In summary, they possessed a variable diet that changed between inland, montane and coastal sites. Two species are recognised, one for the North Island (*Aptornis otidiformis*), occurring in vegetation mosaic areas of open scrub, forest and grassland (Worthy 1999, Worthy & Swabey 2002) and a larger species (*A. (o.) defossor*) from more open, scrubland, sites on the South Island (Holdaway 1989, Worthy 1998, Worthy & Holdaway 1995). The latter species stood at 80 cm in height, roughly the same size as a male Great Bustard (*Otis tarda*) and that of *Pachyornis*, the second largest of the moas. It is the bill that has attracted the most interest, and has given the two species their common name, due to the very superficial similarity to the carpenter's tool of the same name. The most recent study (Houde *et al.* 1997) indicates that the adzebills may be basal to the rail lineage, although other studies suggest relationships with the Kagu of New Caledonia. Aptornithidae is one family whose position is still unclear: one study has even come up with the suggestion

---

Opisthocomiformes and Foro  
3 fossil species, 3 genera

---

Gruiformes  
221–225 fossil species, 109 genera

The Messelornithidae of the early Tertiary were, until recently, thought to be related to the Sunbittern of the Neotropics. However, Gerald Mayr (2004g) of the Forschungsinstitut Senckenberg considers the group to be most closely related to the finfoots and rails. Of the four species so far identified, *Messelornis cristata* is the only one known to possess a fleshy or horny comb.

that they may not be gruiform at all, but, instead, may be distant relatives of the Anseriformes and Galliformes (Weber & Hesse 1995).

The Cariamoidea would also appear to be an aberrant offshoot within the Gruiformes. However, this is deceiving, for, as well as being as old as the Messelornithidae, the fossil record shows a group that was more speciose than the two species we see now. The group consists of four families: Cariamidae (the only extant family); Idiornithidae; Bathornithidae; and Phorusrhacidae. Cariamidae has one valid species in the fossil record: *Chunga incerta*, from the Pliocene of Argentina. An Oligocene species has also been listed, but its relationship with the Cariamoidea has been called into question (Mourer-Chauviré 1981, Olson 1985). The Idiornithidae, predominantly from the Middle Eocene and Early Oligocene of Europe and Asia, and the Bathornithidae, from the Late Eocene and Early Oligocene of North America, are two associated groups that have been treated as subfamilies of the Cariamidae (as per Mourer-Chauviré 1981). The Bathornithidae have a chequered history, with the original specimens being allotted to the Cathartidae, Rallidae and Burhinidae, only being combined and elevated to family status in 1933 (by the original author, A. Wetmore). It was not until 1968 that the family finally found its proper placement alongside the Seriemas (see Olson 1985 for a more complete summary). The Bathornithidae includes two genera: *Bathornis*, which includes *B. grallator* from the Late Eocene of Wyoming, a bird originally described as a 'terrestrial vulture' by Wetmore in 1944; and *Paracrax*, including *P. gigantea* from the Late Oligocene of South Dakota. Within the related Idiornithidae, the genus *Elaphrocnemus* is of particular interest, as the wing elements were 'almost perfectly intermediate between the seriemas and hoatzins' (Olson 1985), leading to his conclusion that the Opisthocomidae and the Cariamoidea were related, a conclusion also reached by Mourer-Chauviré (1981). The Cariamoidea evolved on open grasslands as predatory birds, running down smaller prey from reptiles and other birds to mammals of various types. Some species may also have scavenged. The elegant, long-legged seriemas are one end of the extreme, while the phorusrhacid terrorbirds are the other, some reaching gigantic proportions, their most notable feature being a large head and high-ridged bill. Alvarenga & Höfling re-examined the classification of the terrorbirds in 2003 and concluded that the Phorusrhacidae occurred purely in the Americas. Most of the 17 species so far identified were South American, the majority inhabiting the pampas and dry grasslands of Argentina and Brazil; the exception is *Titanis*. Their origins are suggested to be in the Late Cretaceous or Early Paleocene, when South America was still an island continent. However, the earliest known species is the turkey-sized *Paleopsilopterus itaboraiensis* from the Middle Paleocene of the Argentinian Pampas, which suggests that other species are yet to be discovered. The family lasted until the Late Pliocene, when they had reached as far north as Florida and Texas, through the 2-m tall *Titanis walleri* (MacFadden *et al.* 2007). In the past, the family was also thought to have examples in Europe. However, these two fossils, *Ameghinornis* and *Aenigmavis*, have been removed from the Phorusrhacidae. The former was redescribed as a probable idiornithid and the latter as 'Aves: *incertae sedis*', with the suggestion that *Aenigmavis* was an arboreal, rather than a purely terrestrial, species (Mourer-Chauviré 1981). This observation in itself should have made people suspicious, given the terrestrial nature of the rest of the family. Gerald Mayr (2005b) has since reidentified both these specimens as belonging to *Strigogyps*, a member of the owl radiation, and therefore not even a cariamoid, although this has been countered by Peters (2007). Problems with identification aside, the phorusrhacids have proven to be an interesting family of predatory birds. As with others in the group, these ground-birds were generally built for speed, with members of the subfamily Phorusrhacinae being the top predators of the grassland and sparse scrubland areas they occupied. Those of the Brontornithinae were at least partial scavengers. Studies examining the locomotory abilities of these animals have estimated that the giants of the family, the Phorusrhacinae, could attain speeds of up to 50 km/hour (31 mph), while smaller species, such as the Argentinian *Mesembriornis milneedwardsi* from the Upper Pliocene, may have been even faster, with an ability to run at up to 97 km/hour (60 mph), although probably only for short bursts (Blanco & Jones 2005): these speeds may seem incredible, but today's fastest cursorial bird, the ostrich, can attain similar speeds (see Folch 1992). One particular surprise has come with the discovery of the North American giant, *Titanis walleri*, in that it shows major modifications to the wing. Instead of the reduced wing one would expect in a flightless bird, its forelimbs were surprisingly well developed and equipped with manipulative thumb-claws, providing the adult bird with a two-clawed 'hand', possibly utilised in manipulating prey. Whether other members of the family possessed this adaptation or not is still unknown (Chandler 1994). Thus, *T. walleri* is the only species of bird known to date in which the adult possessed such a two-clawed 'hand', even though a few other, modern groups, namely the Hoatzin (*Opisthocomus hoazin*) and certain turacos, have wing-claws when young.

The family Phorusrhacidae was a widespread group, with representatives throughout Central and South America and with at least one species (*Titanis walleri*) reaching into the southern USA. The most obvious characteristic of the family is the deep, raptorial bill, giving the birds a large-headed appearance quite unlike that of any large flightless bird today, as seen in this reconstruction of *Paraphysornis brasiliensis*.

A further three groups of 'runners' were related to the cranes and rails (Gruides). These were families whose members occupied the grasslands of the Northern Hemisphere from the Eocene to the Early Pliocene: the Geranoididae, a North American radiation in the Eocene and a family that we know little about; the Eogruidae, their contemporaneous Palearctic equivalents, of which one species at least, the Late Oligocene *Sonogrus gregalis* from Outer Mongolia, showed sexual dimorphism in size; and the Ergilornithidae, highly specialised forms from the Oligocene to Pliocene of the Central Asia steppes. These crane-sized birds were highly cursorial, so much so that they were probably flightless or nearly so (Olson 1985). More amazingly, ergilornithids show an evolutionary trend in the reduction of toes, to the extent that species such as the Late Miocene/Early Pliocene *Amphipelargus maraghanus* had just two toes on each foot, a feature shared only with the modern ostrich (Harrison 1981). This remarkable example of co-evolution is an adaptation for running at speed on open terrain, and such a reduction in toes is also shown by plains mammals, most notably the horses (Equidae). In life, these birds must have been amazing to watch, while the habitat that they occupied would have been all the more extraordinary, given that they shared their steppe home with an ostrich.

The origins of the Gruides as a whole are in the Eocene, if not the Paleocene. The cranes are represented in the fossil record by at least 20 species. However, many of these have been described only from fragmentary tibiotarsi, which makes their reconstruction difficult, to say the least. Indeed, the fossil record of the Gruidae is so poor for the early part of their history that doubt has been cast even over some of those bones that are accepted currently as gruid (Mayr 2005a). The oldest recognised cranes include *Geranopsis hastingsiae* from the Upper Eocene of southern England. Even this may turn out to belong to a different group: resemblances have been shown between the coracoid of this species and those of *Anserpica kiliani*, a possible magpie-goose from the Upper Oligocene of France. Modern cranes belong to two subfamilies, the Balearicinae and the Gruinae, and it is thought that these split at a very early stage in the evolution of the family. Today, the Balearicinae are restricted to two African species of Crowned Crane. However, the subfamily was at one time more widespread and more diverse. *Balearica exigua*, smaller than the modern species, was present in North America during the Miocene, alongside the member of another genus, *Probalearica crataegensis*. A member of this second genus, *Probalearica mongolica*, occurred during the Upper Miocene in Europe and the Pliocene of Asia. *Probalearica*, or at least *P. crataegensis*, was described by Olson (1985) as being similar to *Balearica* and he suggested that it may be part of that genus. Of these 'crowned' cranes, *B. exigua* is perhaps the best preserved, with several almost complete fossils uncovered from the ancient damp grassland beds of Nebraska, showing that the habitat for this species was similar to that of the African species (Feduccia & Voorhies 1992). Although the habitat may have been similar, no inferences can be made with regards to the plumage of these ancient balearicine cranes. Whether they bore the tufted crests of today's species or not is unknown; it is more likely that this is a feature of the modern *Balearica* species through the isolation of their ancestor in the Afrotropics. Like these balearicines, the fossil Gruinae show many skeletal similarities with their extant relatives, although the Upper Miocene *Camusia quintanai* from the Mediterranean island of Menorca shares a number of plesiomorphic traits with the Balearicines, despite being placed in the Gruinae (Seguí 2002). Endemic island species have been found elsewhere, with the Pleistocene species *Grus melitensis* from the islands of Sicily and Malta and the Caribbean *Grus cubensis*, another Pleistocene species, but one distinguished by its flightlessness. The origins of the Gruidae remained a mystery until 2005, when Gerald Mayr published a paper describing what he called a 'crane precursor', *Parvigrus pohli* (Parvigruidae), from the Lower Oligocene of Lubéron in southern France, a time when southern Europe was a place of tropical forests (Mayr 2004c). To date, this is 'the most substantial Paleogene fossil record of the Grues' (i.e. limpkins and cranes), 'and [is] among its oldest representatives'. Unlike modern cranes or limpkins, this chicken-sized fossil had a short beak and rail-like limb proportions. *Parvigrus* possesses many features shared with either the cranes or the limpkin and was what can best be described as a mosaic of the two groups. The paper also hints at the evolution of the cranes and limpkins, suggesting that the former evolved into the giant long-legged form that we know today as an adaptation to life on the grasslands and damp marshlands that appeared and spread towards the end of the Oligocene and throughout the Miocene (Blondel & Mourer-Chauviré 1998), while the limpkins evolved in response to a specialised niche, as an adaptation to eating snails in marshland conditions. Within the Gruidae, *Parvigrus* shares most features with the Balearicinae, adding further credence to the perception that this latter subfamily is the more primitive of the two living groups.

The last two groups to discuss are the Otidides and Ralloidea, and these are vastly different in the number of fossil and subfossil representatives they possess. The few

representatives of the bustards are Palearctic in distribution. The greatest number is listed for the Pliocene, for example *Otis paratetrax* from Moldavia and the tentative bustard *Gryzaja odessana*, from the Ukraine, while at least one species is listed for the Miocene of Europe. The Ralloidea may incorporate the Messelornithidae (already described), as well as the Heliornithidae (finfoots) and the Rallidae (rails) (Houde *et al.* 1997, Livezey 1998, Mayr 2005a). Heliornithidae is known only from single fossils of members of extant genera from the Miocene of the USA and the Middle Miocene of Chad. The latter is a species closely related to the Asiatic Masked Sungrebe (*Heliopais personata*), indicating a more widespread distribution for that genus in the past (Louchart, Mourer-Chauviré *et al.* 2005). Rallidae has a more substantial fossil record, although many species are known only from a few bones, so little can be diagnosed as to their living form. The earliest species are known from the Eocene, and include members of the genus *Quercyrallus* from France (Cracraft 1973) and a variety of American species, such as *Eocrex primus*, a relative of the gallinules from Colorado, and *Palaeorallus troxelli* from Wyoming (Wetmore 1931). More substantial records are known for later, European, genera, with, for example, *Rupelrallus* and *Belgirallus* from the Lower Oligocene (see Mayr 2005a, 2006b). The major groups such as the coots, gallinules and marsh-rails had evolved by the start of the Pliocene (Feduccia 1968, Wetmore 1957). A substantial number of these rails were flightless or nearly flightless, especially subfossil species from island habitats. Like so many island species, these Holocene rails fell to the advance of humans and their exotic familiars. Most notable among these were the giant coots of New Zealand and the Chatham Islands (*Fulica prisca* and *F. chathamensis*, respectively), and the Takahes, including the subfossil North Island form, *Porphyrio m. mantelli*, which Trewick lists as a species separate from the surviving South Island form *hochstetteri* (Trewick 1996, 1997). Europe also possessed at least one flightless island endemic whose extinction may be related to the colonisation of its island by early humans during the Pleistocene or early Holocene, namely the Ibizan *Rallus eivissensis*, closely related to *R. aquaticus* (McMinn *et al.* 2005). Other flightless rails have been described from the Americas with members of the genus *Rallus* in Bermuda (Olson & Wingate 2000, 2001) and members of the genus *Nesotrochis* from the Caribbean (see Livezey 1998).

---

Turniciformes  
2 fossil species, 2 genera

Before we leave the gruiforms and their relatives, we should perhaps mention the enigmatic buttonquails (Turnicidae), with their mosaic of characteristics. There is not much to tell fossil-wise, as no turnicid fossils have been found apart from Neogene examples of modern species. In 2000, Mayr described a stem group, the Turnipacidae, from Lower Oligocene deposits at Céreste, France. Two species were listed, *Turnipax dissipata* and ('tentatively') *Cerestenia pulchrapenna*. Evidence indicates that these two families may be an early offshoot of the Charadriiformes, rather than derived from Gruiformes or other ancestors.

---

Charadriiformes  
99–102 fossil species, 61 genera

One theory on the evolution of the neornithines pivots around the existence of a group of birds with a mosaic of characteristics—the so-called 'transitional shorebirds' (Feduccia 1996)—and their subsequent diversification at the start of the Tertiary (Feduccia 2003a). This has drawn major disagreement from many phylogeneticists, particularly because of its reliance on 'a limited fossil record of neornithine birds from the Cretaceous and Paleocene, classified to within just a handful of the modern orders' (Dyke & van Tuinen 2004). Recent work combining the fossil and molecular records suggests that this may be a real phenomenon rather than an artefact of the fossil record (Ericsson *et al.* 2006). One such group that Feduccia included in the transitional shorebirds is the form-family Graculavidae, a globally widespread assemblage that show certain similarities to the modern Burhinidae. However, many examples are fragmentary, while the family has not yet been examined cladistically, which would reveal the relationships within the group and would provide evidence as to whether the Graculavidae should be included in the Charadriiformes in the first place. Whilst other charadriiform fossils have been described for the Paleogene, Mayr (2005a) states that, in Europe at least, modern-type Charadriiformes are not known before the Oligocene. When they do appear on the scene, the majority of these waders closely resemble modern forms, to the point that several belong to modern genera.

For the more unusual diversifications within the order, one has only to examine the Alcidae, a group of pelagic species adapted to underwater pursuit diving, often at the expense of their flying capabilities. The auks, possibly because of their more robust skeletons, have a much stronger fossil record than most other charadriiform families, and have definitive examples as far back as the Middle Miocene. Even at this time alcids were present in both the Pacific and Atlantic oceans. Earlier fossils attributed to the group, namely *Hydrotherikornis* and *Petralca*, are considered by some authors to be of doubtful affinities, with *Hydrotherikornis* closer to the Procellariiformes and *Petralca* being too poorly described to justify inclusion in the Alcidae (see Warheit 2002). Another fossil with alcid affinities, as yet undescribed, has been found in the

Lower Eocene deposits of England and, if this does indeed turn out to be an alcid, would be the earliest member of that group so far found. The major radiation of the auks occurred in the Late Miocene, with the appearance of several genera, modern and fossil. Most of these were Pacific species, including several from the upwellings off the coast of California. Like other seabird groups, flightlessness has occurred in more than one lineage within the family. Many are familiar with the Great Auks (*Pinguinus* spp.) of the north Atlantic, in particular the last species of the group, which was forced into extinction within the last 200 years (see Fuller 2002). However, there is a much older group, from the Late Miocene to Late Pliocene of the Pacific, so distinct that they form a separate subfamily, Mancallinae; indeed, Miller (1946) considered them a separate family, Mancallidae. These auks included *Mancalla californiensis*, a species from California about the size of the Great Auk that showed a more advanced state of evolution towards the penguin-like anatomy of underwater 'fliers' than was evident in the Atlantic *Pinguinus*. Warheit lists three genera in the mancalline radiation: *Mancalla*, with five named species, ranging from the Late Miocene to the Late Pliocene; *Praemancalla*, a less advanced group consisting of two, possibly three, species; and the primitive *Alcodes*, a poorly known mancalline progressing towards flightlessness that was found in the coastal region of California during the Middle to Late Miocene. It is not known why the mancallines became extinct, although a number of possibilities have been suggested, one being extinction through unsuccessful competition for breeding space and food with the Otariidae, the eared-seals, which were becoming abundant during this period (Konyukhov 2002).

Sandgrouse have also been connected with the Charadriiformes, although their fossils do not give us any clues as to whether they are more closely related to the shorebirds or to the pigeons. Indeed, few fossil species have been recorded. The earliest described comes from Upper Oligocene deposits in France. These belong to two genera, *Archaeoganga* consisting of three species, and the more modern *Leptoganga*, with the species *L. sepultus*, from the Upper Oligocene/Early Miocene (see Mourer-Chauviré 1993). Nor can we look to the Columbidae to find these connections, as their early fossil record is also scant. The earliest definitive member of the Columbidae is *Gerandia calcaria*, a small dove from the Miocene of France. Another dove, *Microena goodwini*, was described from the Lower Eocene of the London Clay deposits (Harrison & Walker 1977), but this specimen consists solely of a tibiotarsus, which makes its identification difficult (Dyke & van Tuinen 2004). Indeed, Mayr regards it as a member of the swift/nightjar radiation, rather than a dove (Mayr 2005a). The later record of the Columbidae is more substantial, with a number of subfossil species recovered from Holocene archaeological sites in the Pacific. The giant *Nutunaornis gigoura*, from the island of Viti Levu (Fiji), characterizes the extinct pigeons of the Pacific in that it was the largest of its group; similar trends can be seen with the extinct *Caloenas canacorum* and *Gallicolumba longitarsus* from New Caledonia and *Ducula davidi* from Uvea. *Nutunaornis* is known from a number of bones, including leg and wing bones and part of the beak, from which it can be estimated that the bird was 30% larger than its nearest relatives, members of the genus *Goura*: this species approached the Mauritius Dodo (*Raphus cucullatus*) in size (Worthy 2001).

The cuckoos are another enigmatic group. They have been associated most often with the turacos in modern classifications, and with the occasional inclusion of the Hoatzin, although this is not widely accepted (see Sibley & Ahlquist 1990). The most recent (morphological) analysis of the cuckoos, Hoatzin and turacos, however, placed the last two together with the cuckoos on a separate lineage, but related through a distant ancestor, *Foro*, which may have been predominantly terrestrial in form (Hughes 2000). The fossil record of the Cuculidae itself is too scanty to support or refute this. Although the oldest confirmed species are two small North American species, *Eocuculus cherpinae*, an arboreal cuckoo from the Late Eocene of Colorado (Chandler 1999), and *Neococcyx macrorquodalei*, from the Early Oligocene of Saskatchewan, there are other, Old World, contenders for the title, including *Dynamopterus* from the Eocene/Oligocene of France (Mayr 2006c). However, because this genus is represented by two humeri, one at least (that of *D. boulei*) probably being a member of the raptor genus *Aquilavis* (Olson 1985), more skeletal elements are required before their identity as cuckoos can be corroborated (Mayr 2005a). Another relative of the cuckoos, *Proculiculus minutus*, has been identified from Early Eocene deposits from the south of England, but its placement within the order is also only putative. As we see with so many groups, the difficulties of identification, either through interpretation of the fossils, the need to examine fossils using modern techniques, or even just the fragmentary nature of the fossils themselves, all lead to a confusion of phylogenetic identity. Such is the example of the Parvicutulidae, initially placed alongside the cuckoos, then moved to the catch-all zygodactyl family Primobucconidae in the 1980s, before the realisation that, in fact, they may be relatives of the caprimulgine radiation.

The Mancalline auks show a predominant evolution towards flightlessness, with the last members of the group, the four species within the Pliocene genus *Mancalla*, having flipper-like wings. These early-radiation auks showed adaptations to underwater 'flying' far more advanced than any other alcids, living or extinct, including the famous Garefowl or Great Auk (*Pinguinus impennis*).

---

#### Pterocliiformes

4 fossil species, 2 genera

---

#### Columbiformes

25–26 fossil species, 17–18 genera

---

#### Cuculiformes and Musophagiformes

11–14 fossil species, 10–11 genera

The Eocene fossil *Foro panarium*, discovered in the Lower Eocene Green River Formation of Wyoming, shares characteristics with three groups of birds: the turacos (*Musophagidae*) of Africa; the South American Hoatzin (*Opisthocomidae*); and the more cosmopolitan cuckoos (*Cuculidae*). This mosaic of features has influenced the suggestion that the three groups are related, with *Foro* being another lineage originating from a basal cuckoo-turaco-Hoatzin ancestor.

Psittaciformes  
28 fossil species, 24 genera

What is probably more interesting—a better word may be ‘odd’—is that the majority of known cuckoo fossils are American, when the group is thought to have originated in the Old World. Indeed, according to Hughes (2000), the most primitive extant species come from South-east Asia in the form of the ground-cuckoos of the genus *Carpococcyx*. This new classification is different from that of the Peters *Check-list* used as the starting point for HBW, and the DNA–DNA hybridization classification, but the former makes assumptions as to the evolution of the zygodactyl foot and the occurrence of terrestriality in the family, while the latter had major omissions in its pair-wise comparisons: the studies of Hughes, admittedly, lack molecular work, so may also have flaws in the decisions made, even if it does make a convincing case. If we do assume that Hughes is correct, it is probably to the Old World tropics, with a focus on the east, that one would have to look in order to find early fossils relating to the group. Of the more modern, post-Oligocene, fossils, it is perhaps worth mentioning two in particular. One is the ground-cuckoo *Cursoricoccyx geraldinae* from the Lower Miocene of Colorado (Martin & Mengel 1984), which is the most northerly species of the Neomorphine cuckoos found to date, although this hints more at the climate in North America at the time rather than being a truly remarkable record. The second, *Geococcyx (californianus) concklingi*, is of a Pleistocene relative of the Greater Roadrunner (*Geococcyx californianus*), first found in the Donna County caverns of New Mexico by Hildegard Howard in 1931. This was a large species, which, if the measurements she provides are typical, was more than 10% larger than the modern form of *G. californianus*. However, its wing bones, or, rather, the dimensions of the ulna, are 24% larger, the proportions to the rest of the fossil elements inferring that this bird was perhaps less adapted to cursoriality than is the modern form, with which it was contemporaneous.

The turacos are younger than the cuckoos and are known from as far back as the Lower Oligocene, with an unnamed species listed for Bavaria (Ballmann 1970). Oligocene fragments from Egypt have also been assigned to the family, but Olson (1985) regards this evidence as unreliable. Further species are known from the Lower Miocene of Kenya (*Musophaga africanus*) and contemporaneously from France (*M. meini*). Thus, despite the fossil record for the *Musophagidae* being so meagre, we find that they had an ancient range that included Europe as well as Africa. This may be a surprise to many, until one realises that the early Paleogene was a warmer period than now, with extensive tropical forests across Europe, and elsewhere. *Promusophaga* from the Late Eocene of the USA and London Clay was also considered to be a turaco, but is in fact an example of *Lithornis vulturinus*, and is therefore a member of the palaeognathous family *Lithornithidae* (Leonard *et al.* 2005, Olson 1985).

The parrots have been associated with both the Columbiformes and Cuculiformes or with a number of other zygodactylous species, in particular the Coliiformes, but their actual origins remain unclear (Mayr 2002b). Until recently, very few fossils were available, except for modern parrots from archaeological sites, which did shed some light on the diversity of Pacific parrots prior to human colonisation: for instance, the lorries *Vini sinotoi* and *V. vidivici* from the Marquesas Islands (Steadman & Zarriello 1987), and some modern genera and species from Miocene and Pliocene sites in the Americas and Australia (see Mayr & Göhlich 2004 for a brief review). However, in recent years, parrot-like fossils have been discovered from the Eocene of Europe and North America. Some of these are reanalyses of known, but enigmatic, species, such as ‘*Primobucco*’ *olsoni*, formerly placed in the Piciformes alongside the *Galbuli* (Feduccia & Martin 1976, Houde & Olson 1988): Mayr points out that this species may be better listed as ‘*Pulchrapollia olsoni*’, owing to its possible conspecificity with *Pulchrapollia gracilis* (Mayr 2002b). Some of the new fossils may belong to the *Psittacidae*, e.g. *Xenopsitta fejfari* from the Czech Rebulic (Mlíkovský 1998). Others represent Eocene species from more primitive families. *Pseudasturidae*, for instance, is a group with representatives in Europe and the USA (Mayr 2002b; see also Dyke & Cooper 2000), for example *Pseudasturides* (formerly *Pseudastur*) *macrocephalus*, a Middle Eocene ‘parrot’ from Germany and the type species for the family (Mayr 2002b, 2004a), while others, such as *Bavaripsitta ballmanni* from the Middle Miocene of southern Germany (Mayr & Göhlich 2004), are as yet of unknown affinities. The oldest representatives of the *Psittaciformes* so far known thus occur in Europe and North America, rather than the Southern Hemisphere as one may have expected given the distribution of the majority of extant species. The most remarkable feature of the complete specimens of *pseudasturids* (‘*Primobucco olsoni*’, *Serudaptus pohli* and *Pseudasturides macrocephalus*) is the lack of a parrot-like beak. Instead, they possess something more general in form, which explains the previous confusions. Another family, the *Quercypsittidae*, are known from the Upper Eocene of France (Mourer-Chauviré 1992), but the beak of this family is not known. Given that they are regarded as another family of primitive parrot-relatives, it is not illogical to suppose that these

birds also possessed a generalist unhooked beak, rather than one resembling that of modern-day species. Other species included in the Psittaciformes at one time or another have now been assigned to other groups. Included among these is *Palaeopsittacus* from the London Clay (Harrison 1982): currently regarded as *incertae sedis*, this species shows similarities with the frogmouths (Mayr 2003b). One problematic find is that of a jaw fragment from the Cretaceous of Montana (described by Stidham in 1998). However, its identity as a bird, let alone as a parrot, has been contested by Dyke & Mayr (1998).

Owls were also thought to have fossil representatives in the Cretaceous. However, these have since been shown to belong to a group of theropod dinosaurs! Currently, the honour of 'oldest owl' belongs to the Paleocene *Ogygoptynx wetmorei*, described from a fossil tarsometatarsus found in SW Colorado (Vickers-Rich & Bohaska 1976) and *Berruornis*, a large owl originally described from the Upper Paleocene of France. Both belong to fossil families, the Ogygoptingidae being monotypic, while *Berruornis* joined several other owls in the Sophiornithidae, a European family that existed from the Upper Paleocene to the Oligocene, and included the Eocene/Oligocene *Sophiornis quercynus*. The fossil record of owls is fairly extensive compared to other land groups, with at least six families present, consisting of about 90 species. Several species come from the Paleogene of Europe and North America, including members of the family Protostrigidae, whose type genus, *Protostrix*, was synonymised with *Minerva* (Mourer-Chauviré 1983). The protostrigids are thought to be the sister-group to the tytonid and strigid lineages (Mourer-Chauviré 1987). *Minerva* spp. were large owls, about the size of *Bubo*, for which members of the genus were originally mistaken. The relationship among the different owl groups, particularly between these ancient groups and the modern families, still needs to be understood properly. What can be said is that owls were far more diverse in the early Paleogene than they are now. Recently, the supposed Eocene raptor *Messelastur* from Europe has also been connected with the owls, being similar to *Tynskya eoceana*, an 'owl' from the Green River Formation of Wyoming: together, they constitute a sister-group to the Strigiformes, rather than being ancestral to them, and, controversially, unite the clade (Messelasturidae + Strigiformes) as the sister-group to the raptors (Falconidae + Accipitridae) (Mayr 2005h). Of the modern families, Tytonidae is the older, and was more diverse during the Paleogene, with two subfamilies in existence prior to the modern subfamilies. The *Necrobyinae* consisted of *Nocturnavis incerta*, a species from the Eocene and Oligocene deposits of the Quercy Fissures in France, and *Necrobyas*, also from Quercy (Mourer-Chauviré 1987; see also Bruce 1999). The tarsometatarsus of these owls is similar to that of the modern barn-owls, but is shorter and stockier. Several other 'modern' owls have been described from Paleogene Europe, mostly from Quercy, including *Selenornis henrici*, member of a second tytonid subfamily, Selenornithinae. Modern-type tytonids are not known until much later, with the majority of species coming from the Pleistocene and Holocene. Sexual dimorphism existed in at least some of these fossil *Tyto*, for instance the Pleistocene *T. neddi* from the Caribbean island of Barbuda (Steadman & Hilgartner 1999), and *T. mourerchauvireae*, a large owl from the Middle Pleistocene of Sicily (Pavia 2004). Several of these extinct tytonids, including the Pleistocene *T. balearica* of the western Mediterranean, were giants in the family, while some were merely large versions of the typical barn-owl type. Studies on sites where groups of tytonid species existed suggest that competition between the different species caused them to evolve into different size-class niches, a phenomenon that also involved the related strigid owls. For instance, during the Pleistocene, Cuba possessed three *Tyto* owls, one being *T. alba*, one substantially larger (*T. noeli*) and the last, *T. riveroi*, being a true giant, the size of an eagle-owl. Also present in this 'series' was a truly huge, probably flightless, strigid owl, *Ornimegalonyx oteroi* (Arredondo 1976, 1982). Gigantism therefore is not restricted to the Tytonidae, and nor are they all fossils, for they include such species as the Great Grey Owl, *Strix nebulosa*. Most famous of these giants is probably the La Brea Owl, originally described as a form of the Great Horned Owl (*Bubo virginianus*) but later recognised as being a species in its own right, not related to *Bubo*, but to the Barred and Spotted Owls, with which it was compared (Howard 1933) and thus given the name of *Strix brea*: to date, it does not seem to have been compared with the even larger *S. nebulosa* (Feduccia 1996). There is one special group of 'normal-size' owls that were specialist hunters of birds. These were members of the genus *Gallistrix*, which inhabited the islands of Hawaii until fairly recently. They possessed short, rounded wings and long legs similar to those of an *Accipiter*, occupying the niche these hawks would have occupied had they been on the islands. Each of the major islands had its own species of *Gallistrix*, with *G. auceps* on Kauai, *G. erdmani* on Maui, *G. geleches* on Molokai and *G. orion* on Oahu. As with so much of the avifauna of the Hawaiian Islands, human colonisation was their downfall, despite their abundance in the fossil deposits. Today, only two owl species exist

#### Strigiformes

84 fossil species, 29–30 genera

*Ornimegalonyx oteroi* was a huge, possibly flightless, strigid owl from the Late Pleistocene of Cuba, its measurements suggesting a bird about twice the size of the modern Eurasian Eagle-owl (*Bubo bubo*). Among its most notable features are its long heavy toes armed 'with the most powerful claws possessed by any strigiform bird' (Arredondo 1976). Given the virtual absence of mammalian predators on the island (with the exception of a fossil dog), this owl must have been one of the top predators, and the scourge of the larger herbivorous mammals.

---

Caprimulgiformes and relatives  
23 fossil species, 19 genera

on the islands, the Hawaiian endemic subspecies of the Short-eared Owl (*Asio flammeus*), thought to be a recent colonist (see, e.g., Burney *et al.* 2001 and Olson & James 1982), and the introduced Common Barn-owl (*Tyto alba*).

The superficially owl-like Caprimulgiformes are also an ancient lineage, with the oldest current examples originating from the Eocene. The Paleogene saw the existence of species belonging to modern families as well as others that have no modern equivalents. Included among these are the enigmatic Fluvioviridavidae, consisting of two species from the Eocene of North America and Europe (Mayr 2005i, Mayr & Daniels 2001), although these have still not been placed definitively in a known order. An extinct group of definite nightjar-relatives, the Archaeotrogonidae, were found in European deposits. Assigned to the trogons from the initial description of *Archaeotrogon* in 1892, similarities with the Caprimulgiformes were noted in 1980, when Cécile Mourer-Chauviré described the family as *incertae sedis*. It was not until 1995 that she moved the family into the Caprimulgiformes. Archaeotrogonidae consists of five small species. Four belong to the genus *Archaeotrogon* of the Quercy fissures, with *A. venustus* having the greatest temporal range, from the Late Eocene to the Late Oligocene, the other three being restricted to the Oligocene (Mourer-Chauviré 1995b). The fifth species is *Hassiavis laticauda*, a putative *Archaeotrogon* from the Middle Eocene of Messel, and, at about 13 cm in length, the smallest as well as the oldest species in the group. This last species already showed adaptations to catching insects on the wing. In particular, it had a short, wide beak, most similar to that of the owlet-nightjars, although this may be the expression of plesiomorphic characteristics, rather than any sign of direct relationships (Mayr 2004c). Additionally, *Hassiavis* is preserved with its feathers, and those of the tail are distinctly barred, as in the majority of modern Caprimulgiformes. Paleogene Europe hosted species of at least two other extant families, both now restricted to the tropics. Three species of potoo (Nyctibiidae) have been recorded from Europe, with *Euronyctibius kurochkini*, identified from an incomplete humerus from the Upper Eocene/Oligocene deposits of France (Mourer-Chauviré 1989b), and members of the genus *Paraprefica* from the Middle Eocene of Germany (Mayr 1999b, 2005m). The latter have a mosaic of characters, with the derived skull and tarsometatarsus of modern species, but otherwise showing a more primitive structure, and thus indicating their status as stem-lineage representatives. The only other nyctibiid fossils are of a modern species, within the current, South American range of the family. A similar tale can be told for the frogmouths (Podargidae), with two age groups of fossils, one from Quaternary deposits of Australia, the other from the early Paleogene of Europe. The European frogmouths consist of two species, with an additional species regarded as 'putative'. The first of these three to be discovered was originally considered to be a parrot. However, *Palaeopsittacus georgei*, as it is known, may be a stem-lineage representative of the Podargidae and is very similar to the French *Quercypodargus olsoni*, which is a primitive frogmouth. Paleogene fossils pertaining to the oilbirds and owlet-nightjars have also been putatively identified from isolated bones from Europe. However, further specimens are required to confirm their presence. The only confirmed oilbird fossils (*Prefica nivea*) come from the Lower Eocene of the Green River Formation of Wyoming.

The earliest confirmed representative of the Aegothelidae is a small, partially associated specimen from north-west Queensland. However, it is during the Quaternary that we find some surprises pertaining to this family, including a species from the Pleistocene of New Zealand, *Aegotheles novaezeelandiae*, a more terrestrial species than those that remain today, although it is similar to, but longer legged than, the New Caledonian Owlet-nightjar (*A. savesi*), an endangered, species also known from a few Pleistocene fossils. As with many of New Zealand's birds, *A. novaezeelandiae* became extinct with the advent of Polynesian colonisation, although its actual demise seems to have been due to the introduction of the Pacific rat (*Rattus exulans*), which initiated its decline 1000 years prior to widespread Polynesian settlement (Holdaway *et al.* 2002). The most widespread and speciose of the families today is the Caprimulgidae. However, this family has a very poor fossil record, and little can be said as to the evolution or even prehistorical extinctions within the group.

---

Apodiformes  
22–24 fossil species, 14–16 genera

The origins of the Caprimulgiformes have recently been discovered to be closely tied to the evolution of another aerial group, the Apodiformes. The major twist in the story came when Mayr (2002a) discovered that the owlet-nightjars may be more closely related to the Apodiformes than they are to the other caprimulgiform families. The discovery began with the analysis of an Eocene family of basal swifts, Aegialornithidae, which bore striking resemblances to recent Caprimulgidae and Aegothelidae, as well as resembling another contemporaneous 'caprimulgiform' family, Archaeotrogonidae. The close relationship of the whole clade, Cypselomorphae, has been further bolstered by the discovery of the aerial-hawking *Protocypselomorphus manfredkelleri* from the Messel; it appears to sit phylogenetically outside this clade as its sister-taxon

(Mayr 2005j). The phylogenetic position of Archaeotrogonidae, however, remains uncertain. Both the Aegialornithidae and Archaeotrogonidae were amongst the most abundant small birds in the Upper Eocene of Europe. Temporally, they existed from the Middle Eocene to the Lower Oligocene, with fossils found in Germany and France (Mayr 2003a, Mourer-Chauviré 1980, Peters 1998); indeed, their temporal range may even have extended as far back as the Early Eocene, as recent finds in North America suggest (Olson 1999). The early swifts, such as *Aegialornis gallicus* of the Quercy fissures, were similar to modern tree-swifts in general form (Mayr 2003a). At least two other groups of swifts overlap with these birds. One, *Eocypselus vincenti*, is a tiny species known from an incomplete specimen from the Lower Eocene London Clay. It is one of the most primitive swifts, and is placed in its own family, the Eocypselidae, although it has also been placed alongside the Hemiprocnidae (Mourer-Chauviré 1988): like the aegialornithids, this latter resemblance may be more due to superficial, plesiomorphic similarities than to any true relationship. The Apodidae have records in the Early Eocene of Denmark and the Middle Eocene of Germany, in the form of *Scaniocypselus wardi* and *S. szarskii* respectively. Like modern species, these birds (or, *S. szarskii*, at least) had long wings and a short tail that was hardly forked. Given their structure, they probably hunted much in the way of modern species. However, the most remarkable discovery has to be that hummingbirds and at least some of their ancestors existed in Europe in the Paleogene, if not elsewhere in the Old World. Primitive hummingbirds were first described in the late 1980s from a tiny bird discovered in Lower Oligocene deposits in the Caucasus. This was named *Jungornis tessellatus*, and allotted a new family, Jungornithidae (Karhu 1988); another specimen of *Jungornis* was recently discovered dating to the Late Eocene of France, extending both the temporal and geographical ranges of the genus (Mourer-Chauviré & Sigé 2006). Since then, other species have been described, for instance *Argornis caucasicus*, from the Upper Eocene, a less specialised bird than *Jungornis*, and *Parargornis messelensis* from Germany. These were initially placed in the Jungornithidae, but doubt has been cast over this: they may represent separate lineages on the evolutionary line towards modern-type hummingbirds. Other than *Parargornis*, these stem-hummingbirds are known only from wing bones of single specimens. The *Parargornis* fossil is particularly striking, as it is a fully feathered specimen (Mayr 2003), and thus can be used to gain a lot more information about these tiny 'micro-swifts'. *Parargornis* had a swift-like bill, but a long tail like that seen in some modern hummingbirds. However, its wings were broad and rounded, unlike any other apodiform known. At a length of 13 cm (with the long tail feathers), this bird was tiny, like others in the group. What is apparent from the wing and tail is that the bird was not adapted to gliding, although it may have captured insects on the wing. The suggestion is that *Parargornis* fed in dense vegetation and may have adopted a flycatcher-like hunting strategy, with the tail enabling great manoeuvrability. None of these, though, are true hummingbirds. The modern, trochilid, nectar-feeding hummingbirds probably diversified in the Neotropics in the Late Miocene (as per Bleiweiss 1998a, 1998b), but their origins are thought to extend back to the Paleocene (Bleiweiss 1998c). However, in 2004 a totally unexpected find was described from the Early Oligocene of Germany (Mayr 2004d), when a 'basal hummingbird' was described and given the rather appropriate name of *Eurotrochilus inexpectatus*. Other than a few bones from the late Quaternary, this is the only other fossil that can be attributed to the family. About the size of a Rufous-breasted Hermit (*Glaucis hirsutus*), *Eurotrochilus* resembled modern hummingbirds in several ways, not only in size, but in bill type and wing form, together inferring nectarivory over other forms of foraging, although it must be stressed that there is no direct evidence to 'confirm' this observation (Mayr 2007). What this fossil does do is provide an Old World origin for the Trochilidae, contrary to what their current distribution would suggest, and it brings into focus the possibility that some Old World flowers of ancient lineage may have evolutionary traits related to a co-evolution with hummingbirds, for example the ericaceous *Agapetes* from the Himalaya (see Mayr 2004d).

Evidence from Europe and North America suggests that during the early Tertiary the passerines were largely absent. Consequently, the niches that they would subsequently take over were open to occupancy by other, non-passerine, groups for at least 30–40 million years before their arrival and domination. One group, that including *Parargornis*, had moved into a niche now occupied by flycatchers and some warblers: *Parargornis* may even have foliage-gleaned, much as the prediction for the original proto-hummingbird has been described, hovering below and around the leaves, picking off the insects it found. A myriad of zygodactyl forms and other so-called 'near-passerines' occupied other 'passerine' niches. This diversity of small birds can be exemplified best through exploration of the mousebirds (Coliiformes), which today contains a single family (Coliidae) of only six species, all confined to the continent of

The enigmatic mousebirds of the family Coliidae represent a relictual lineage of a group of arboreal birds. In the early Tertiary, their diversity in form was much greater, with icterid-like members and birds with a more generalist bill, as seen in this *Sandcoleus copiosus*. Like modern colies, it was capable of a zygodactylous grip, as well as pointing all toes forward, an adaptation that would help it get purchase on twigs and branches as it clambered about in the canopy.

Africa. However, the fossil record lists 15 species, in two main families, from the Eocene of Europe and North America. The second family is the Sandcoleidae, originally described from the Paleocene and Lower Eocene of North America (Houde & Olson 1992), when the several species, including the Lower Eocene *Sandcoleus copiosus*, were given a family, and order, of their own. One of their number, *Eobucco*, was a ubiquitous genus in North America, with *E. brodkorbi* from the Middle Eocene (Feduccia & Martin 1976) and at least two other species from Wyoming (Houde & Olson 1988). These birds bore many mousebird-like features, from the long, tapered tail without strengthened shafts to a large pygostyle (a unique feature of the Coliiformes). Like *Sandcoleus*, *Eobucco* had a slightly curved beak, larger than that of modern colies, giving both genera a superficial resemblance to some cuckoos. Sandcoleids, like the Coliidae (see de Juana 2001), were notable for their foot structure, as it is thought that they could rotate their toes either into a pamprodactyl position (like many swifts, probably as an aid to clinging onto vertical surfaces) or have their toes in a zygodactyl, 'yoke-toed', position. In general, the sandcoleids were generalists feeding on seeds, fruits and similar items. Of particular interest is *Chascacocolius*, described as a sandcoleid, but with some osteological differences to the type genus, and possessing two known species, one, *C. oscitans*, from the Lower Eocene of Wyoming (Houde & Olson 1992), the other, *C. cacicrostris*, a larger bird recently described from the Middle Eocene of Messel, Germany (Mayr 2005f). Only the latter is represented by a complete, articulated, skeleton: it reveals that at least *C. cacicrostris* possessed a pointed, conical bill most similar in form to modern icterids such as the caciques (*Cacicus* spp.). It may be that the species fed in the same way, plunging its bill into fruit and then opening it slightly (a method known as 'gaping'), thereby breaking it open. Several other coly-like birds are known from Eocene and Oligocene Europe. *Selmes absurdipes* has been described from a number of specimens from Middle Eocene deposits of Messel, including two articulated skeletons as well as numerous isolated bones (Mayr & Mourer-Chauviré 2004a). This species has a generalised beak, as in the Sandcoleidae, and a more elongate foot than modern colies, although it is thought to possess the same grasping ability. Originally, it was described as a sandcoleid (as per Peters 1999), but Mayr and Mourer-Chauviré have since indicated that this is a primitive mousebird closely related to the Coliidae. *Oligocolius brevitarisus*, is also closely related to modern mousebirds. This species, from the Lower Oligocene of Germany (Mayr 2000b) has more strongly developed wings than modern mousebirds and a shorter tarsometatarsus: together, these suggest a bird adapted for a more arboreal lifestyle, with adaptations towards more sustained flight than modern species. Other coliids recorded include *Masillacolius brevidactylus*, a pamprodactyl species from the Messel, two species in the genus *Primocolius* (*P. minor* and the larger *P. sigei*) from the Quercy deposits of France, while the only fossil representatives of modern genera are found in Africa, coming from the Early Pliocene (Vickers-Rich & Haarhoff 1985).

Trogoniformes  
4 fossil species, 3–4 genera

The trogons are another group where there are several examples in the fossil record, but their origins are not clarified by their early Tertiary representatives, even though these are close to the origination time of the group. Nor do they clarify their relationships with the Coraciiformes (within which they are sometimes placed), nor with the Coliiformes nor the Steatornithidae, with both of which they have recently been linked. Also, contrary to what one would expect given the modern distribution of the family, the oldest fossils known are European. The oldest articulated specimen was from the Middle Eocene of Messel, Germany (Mayr 2005e), and was tentatively placed in *Primotrogon*. This species, *P. pumilio*, resembled modern trogons in its overall morphology and in possessing a heterodactyl foot, in which the second toe is permanently turned backwards: this unique foot structure is found only in trogons. This species is very similar to *Primotrogon wintersteini*, from the Middle Oligocene of France. However, the two species differ in size, with *P. pumilio* being about 10 cm long, and therefore the smallest member of the Trogoniformes, and *P. wintersteini* being roughly 120% larger. They are separated not only by a considerable period of time (some 16 million years), but also by habitat, the former occurring in tropical forest, the latter living in arid woodland or scrub: further studies may reveal that they belong to separate genera. The skulls of these early trogons differ significantly from their modern counterparts: in particular, that of *P. wintersteini* is narrower, with a narrower beak and smaller eye-sockets, suggesting that the bird was less adapted to foraging on flying insects than modern species (Mayr 1999). *P. wintersteini* is generally similar to the Asian trogons, which are also less reliant on insects, and which take a substantial amount of fruit in their diet, unlike the more specialised African species (Collar 2001). A much larger species, *Septentrogon madseni*, has been found recently in the deposits of the Fur Formation of Denmark, dated as latest Paleocene to earliest Eocene (Kristoffersen 2002), but this bird consists only of part of the skull, enough of which

exists to ascertain that the species was also different from modern forms. There are a number of later examples of trogons, but these are very similar to modern species. Trogons do not occur in the Americas until the Pleistocene, which is in agreement with the suggestion that the Neotropical species are the most derived of the group.

The Coraciiformes *sensu lato* are regarded by many as a polyphyletic group. For instance, HBW divides the Coraciiformes into the Trogoniformes and Coraciiformes, while Sibley, Ahlquist and Monroe went further, splitting from the latter the Bucerotiformes, Upupiformes and Alcediniformes (Sibley & Ahquist 1990, Sibley & Monroe 1990). Mayr has suggested that the Cuckoo-roller (Leptosomidae) should also be removed from the Coraciiformes (Mayr 2002c). It is argued that the roller-like appearance of the Leptosomidae is more to do with the expression of a 'generalist, primitive-percher' morphology than being an indication of true close relationships within the order. The current distribution of the Leptosomidae, the island of Madagascar, is relictual, as its ancient distribution stretched at least as far north as Europe. Including these fossils, Leptosomidae consists of two genera, the extant Malagasy *Leptosomus*, and the European *Plesiocathartes*, the first species of which, *P. europaeus*, was originally described in 1908 as a cathartid vulture from an incomplete tarsometatarsus from Middle Eocene to Oligocene deposits of France (Mayr 2002c). It is only recently that other specimens of the genus have been discovered, *P. kelleri* from the Middle Eocene of Messel and *P. gaillardii* from the Early Miocene of Spain, plus isolated bones from elsewhere in Europe. The most basal group within the Coraciiformes, however, is the Primobucconidae. This is an enigmatic family whose scientific history is fairly complex. Its establishment in the mid-1970s saw the inclusion of many small arboreal species from the Eocene of North America, most of which (with the exclusion of *Primobucco mcgrewi*) have since been removed to families as diverse as Sandcoleidae and Pseudasturidae. The primobucconids were considered by the original authors to be related to the puffbirds (Feduccia & Martin 1976), but they were moved to the Coraciiformes in 1988, being placed close to the ground-rollers (Houde & Olson 1988). Currently, studies indicate that the primobucconids were a primitive family of tiny rollers (Mayr & Mourer-Chauviré 2004b). The most recent discoveries, two specimens of the Middle Eocene species *P. frugilegus* from Germany, show that at least this species was a seed-eater, all the more remarkable considering that modern rollers are all carnivorous. However, there are indications that the primitive trait within Mayr's Coraciiformes and 'Alcediniformes' is of a generalist feeder, rather than a carnivore: primitive members of the kingfisher radiation, the motmots, incorporate vegetable material (in this case fruit) in their diet, while the other basal roller family, Eocoraciidae (the Messel *Eocoracias brachyptera*), was a seed-eater. One more family of rollers existed, again in Europe: these were the Geranopteridae, whose members extend from the Late Eocene to the Early Miocene. Like the Eocoraciidae, these birds bore a mosaic of roller and ground-roller characteristics, although, in this case, there are more similarities to the latter (Mayr & Mourer-Chauviré 2000).

The fossil record of the alcedinidine and meropine groups in comparison is poor. The earliest fossil that can be attributed to them is *Quasisyndactylus longibrachis*, a tiny Middle Eocene tody-like bird from the Messel (Mayr 2004c). This fossil bears a mosaic of characters, some of which are shared with the kingfishers and their kin, others shared with the related Coracii. Its tody-like bill, however, is probably due to convergence with the todies rather than to any direct relationship, as a similar bill type has evolved independently among the motmots. Fossils of 'true' todies (Todidae) are present in the early Tertiary, but not from the current range of the family. Rather, they come from: North America, in the form of *Palaeotodus emryi*, from the Lower Oligocene of Wyoming; and from France, with *P. escampsiensis* from the Upper Eocene, and *P. itardiensis* from the Oligocene, the identity of this latter group requiring further study. These birds were larger than modern species, with *P. emryi* having proportionately longer wings, suggesting a greater power of flight than in *Todus* (Feduccia 1996). The Lower Oligocene *Protornis glarniensis* from Switzerland was another member of what is today regarded as a purely Neotropical group. Formerly considered a motmot, this species is now interpreted as belonging to a more primitive lineage, related to both the todies and the motmots (Cracraft 1980, Mayr 2005a). True motmots are known only from the Americas, with a Miocene record of a humerus that is indistinguishable from three of the six currently recognised genera, while fossils of modern species have been discovered from prehistoric sites in the Neotropics (Becker 1986b). Of the other groups, the true kingfishers (Alcedinidae) possess a number of ancient examples. For example, the oldest halcyonine, which might even be a member of the modern genus *Todiramphus*, was discovered recently in the Miocene Riversleigh deposits of north-west Queensland (Boles 1997).

The final coraciiform families to consider are the hornbills and hoopoes. The fossil record of the former consists of two ground-hornbill species, *Bucorvus brailloni*,

---

#### Coraciiformes

27 fossil species, 17 genera

Today, we are aware of only two morphological types of hoopoe: those that spend much of their foraging time on the ground (*Upupidae*); and those that forage on tree trunks and branches within the canopy of trees (*Phoeniculidae*). One further group, those that foraged among the foliage in a similar manner to leaf-warblers (*Phylloscopus*), has completely disappeared. *Messelirrisor parvus* is one example of this 'hidden' radiation. Messelirrisorids were an abundant group in the Eocene of Europe, with several forms being described from Messel, the type locality.

Piciformes  
16–17 fossil species, 14–15 genera

Other zygodactyl forms  
8 fossil species, 4 genera

from Middle Miocene deposits in the Atlas Mountains of Morocco (Brunet 1971, Olson 1985), and the European *Euroceros bulgaricus* from the Late Miocene (Boev & Kovachev 2007), both of which appear to be primitive relatives to the modern species. Other fossils have been attributed to the hornbills, including *Geiseloceros*, formerly regarded as the earliest member of the group. However, it had a very short wing, unlike all modern species, and is thought now to be a member of the Idiornithidae (Mayr 2002e). One coraciiform was originally considered a member of the hornbills, namely *Cryptornis antiquus*, from the Upper Eocene of France, but it is regarded by Mayr and Mourer-Chauviré (2000) as a possible member of the roller-family Geranopteridae, and is possibly conspecific with *Geranopterus alatus*, also from Eocene Europe. However, *Cryptornis* is too poorly preserved to make a proper analysis and its correct placement awaits a better preserved specimen. This leaves us with little to go on as to the appearance of the early hornbills. However, the same cannot be said for the hoopoes, where there is at least one new family (Messelirrisoridae) from the Middle Eocene of Europe, the latter being regarded as the earliest known representatives of the hoopoe/wood-hoopoe lineage. Messelirrisorids were tiny hoopoe-like birds with curved bills, and may have had a similar diet to the modern forms (Mayr 2000c). The family includes three species, *Messelirrisor parvus*, *M. halcyrostris*, and the largest species, *M. grandis*. The Messelirrisoridae occupied a niche not utilised by either hoopoe families today, being adapted for foraging in branches of trees, unlike upupid hoopoes, but were not adapted to tree-climbing, therefore unlike the woodhoopoes. They were an abundant group during the Eocene, with several specimens found in the lacustrine deposits of the Messel, plus isolated bones from sites in Britain and France. However, there is a huge gap between these early fossils and the only upupid fossil species known (the flightless Pleistocene/Holocene *Upupa antaios* of St Helena: Olson 1975), while Miocene species have been described for the Phoeniculidae, including a tiny specimen described from the Lower Miocene of Bavaria, which may be another messelirrisorid.

The earliest members of the Piciformes *sensu stricto* also appear to be European, with the earliest record being a fragmentary tarsometatarsus from the Lower Oligocene of Belgium, the next record being of a slender tarsometatarsus from a tiny modern-type piciform from the Upper Oligocene of Germany that was not as well adapted for climbing as modern species (Mayr 2001b). Unfortunately, it is too fragmentary to be given a name, or even allocation to family within the order. The Miopiconidae, tiny birds so far only found in Miocene deposits of Morocco, are the nearest relatives to this group. The oldest articulated fossil of a barbet is that of the recently described *Rupelramphastoides knopfi*, a tiny bird from the Lower Oligocene of Germany whose overall resemblance to toucans is likely to be another example of convergence on a similar niche (Mayr 2005g). Despite its appearance, this species is regarded as a primitive omnivore or generalized insectivore within the Piciformes (Mayr 2006d). Another genus, *Capitonides*, is a member of the Capitonidae, overall being similar to the modern genus *Trachyphonus*. However, unlike the latter, which are exclusively African, *Capitonides europaeus* and *C. protractus* both come from the Miocene of Europe. Woodpeckers are comparatively late in the fossil record, being known primarily from Pliocene and Pleistocene deposits. For instance, *Pliopicus brodkorbi* was a small, slender, Melanerpine woodpecker from the Lower Pliocene of Kansas (Feduccia & Wilson 1967), contemporaneous with another, larger, species, *Palaeonerpes shorti* from Nebraska. The latter was a species similar to Melanerpines in form, but may have been part of an earlier lineage of woodpeckers, now extinct (Cracraft & Morony 1969). Pleistocene species include among their number such forms as *Dendrocopos submajor*, the ancestral species to the modern *D. major*.

There are a number of other small arboreal fossils whose relationships were unclear until recently. Most of these were discovered in Europe or North America in the past decade. The majority of this motly collection of birds originate from the Paleocene to Eocene epochs, although one family, the Zygodactylidae, occurred in the Lower Miocene. Some families, for example Primoscenidae, were among the most abundant of small birds during the early Tertiary. Of all these odd little birds, perhaps special mention should be made of *Gracilitarsus mirabilis* (Gracilitarsidae). This species possessed a body plan very different from any living bird (Mayr 2001a). Although it had a long metatarsus like all these little birds, its toes were unusually short. Its claws, however, were rather deep in cross-section, indicating a possible adaptation for hanging onto vertical surfaces. *Gracilitarsus* also possessed a 'swallow-like wing length', suggesting rapid flight capabilities, although no interpretation can be made of the full wing length since the remiges are poorly preserved; the tail feathers are lacking. *G. mirabilis* possessed a bill very similar in shape to that of *Anthreptes* sunbirds, yet it may also have been rhynchokinetic—that is, possessing a flexible tip that can be flexed upwards by muscles present in the bill, as seen today in snipe, pigeons and humming-

birds; generally, this type of bill suggests a nectarivorous bird. As its discovery predates *Eurotrochilus*, this bird holds the prize for being the first described probable nectarivore from the early Tertiary. Like *Eurotrochilus*, its phylogenetic relationships show a connection with birds present only in South America. Now *Gracilitarsus* has been shown to be a primitive piciform-relative (Mayr 2005k). The Zygodactylidae and Primoscenidae are more enigmatic, and while Mayr states that they are 'unquestionably closely related' the most recent cladogram presented (Mayr 2004b) shows two possible alternatives, one in which the two families are split, with the Primoscenidae being basal to the Piciformes + Galbuliformes, the other in which the two cluster together and are positioned as the closest relatives of the Passeriformes. Further specimens are required to resolve this fossil quandary.

The fossil record of the Passeriformes is particularly sparse when compared to the other major orders. In recent years, a number of passerine specimens have been identified, although, to date, it is only the more recent forms that have been complete enough and distinctive enough to be assignable to identifiable taxa. One major problem with any attempt to classify passerines on the basis solely of skeletal material is that the skeleton itself shows a remarkable uniformity within the order. It is only with very recent techniques that microstructural differences have proven to show up features diagnostic for even the major groupings. It has aided the partial identification of some of the older fossils. Having said that, several passerines are worthy of mention. Although many can not be given names, some of these relate to the age and southern derivation of the group, while others show what can happen when passerines become isolated on islands.

One of the major controversies when dealing with the Passeriformes has been the timing of their appearance and spread. Due to the modern-day distribution of the suboscines, traditionally regarded as the oldest passerine suborder, it has been surmised that the Passeriformes have a southern origin, and that it is only with the advent of the oscines that the Passeriformes spread to the Northern Hemisphere. It was therefore timely that, in the mid-1990s, Australian passerine fossils of Early Eocene age were discovered from the Murgon range in south-east Queensland, thereby predating the oldest (Miocene) European fossils known at that time. However, like many passerine fossils, these were rather fragmentary in nature, and their identification to a recognisable taxon within the Passeriformes has proven impossible (Boles 1995). Recent studies have shown that the Acanthisittidae are the only extant members of a previously unrecognised group of ancient passerines (Acanthisittia) which are the sister-group to all other living passerines (Eupasserer) (Ericson, Christidis *et al.* 2002, Ericson, Irestedt & Johansson 2003). In 2004 and 2006, Mayr and Manegold reported on German and French passerines from the Early Oligocene, 10 million years before the time when the Passeriformes were thought to have entered Europe. These birds, originally described as suboscines, held further surprises, in particular that they fell outside the Eupasserer and could belong to a more primitive group. There were yet more surprises, as these primitive forms showed a finch-like bill for feeding on seeds or fruit, not insects, thus upsetting yet another hypothesis about passeriform evolution, which relied on an insectivorous ancestral form. Other European fossils have since been investigated more thoroughly and some, too, fall outside the living passerine groups, showing a wide radiation of so-called primitive passerines in Europe in the early Tertiary (Manegold *et al.* 2004, Mayr & Manegold 2006a). Some specimens belonging to this ancient European radiation have recently been given the name '*Weislochia weissi*' (Mayr & Manegold 2006b). The origins of the Passeriformes are still thought to be on the southern continent of Gondwana, as per the original observations. Many 'later' species of passerines are attributable to modern families, for instance the Miocene *Menura tyawanoides* of Riversleigh, Australia, and even among these we find geographical surprises, such as records of drongo in Pleistocene Europe. However, it is the island species that show the most interesting traits among the Passeriformes. For instance, only three species of passerine are truly flightless. One, the Stephens Wren (*Traversia lyalli*), still existed during European colonisation of New Zealand. The second is another New Zealand Wren, popularly-called the Long-billed Wren (*Dendroscansor decurvirostris*), a species whose overall appearance might have been similar to a rather small, fat-bodied treecreeper. This species probably became extinct during the Maori colonisation, although the species is only known from three sites, all on the South Island (Millener & Worthy 1991, Worthy 1998). Many of the New Zealand wrens show a trend towards flightlessness, so to find two truly flightless species among their number is probably not such a surprise, unlike the third species. This was an emberizid, described as the 'Long-legged Bunting' (*Emberiza alcoveri*) and found on the island of Tenerife in the Canaries. It occupied the Laurel forests of the island at least until the early Holocene. Larger than any living *Emberiza*, *E. alcoveri* was 39% heavier than one of its closest relatives, Cabanis's Bunting

---

Passeriformes and relatives  
90 fossil species, 60 genera

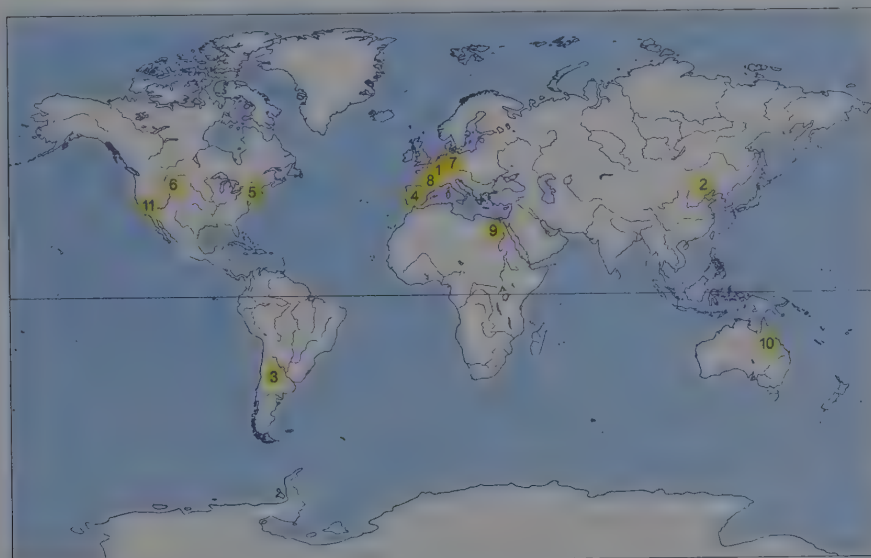

The flightless Long-legged Bunting (*Emberiza alcoveri*) was discovered in La Cueva del Viento, Tenerife. This outsize bunting either inhabited the laurel forest or the ecotone between the lowland laurel forest and the upland Canary pine forest. The reduction of laurel forest and introduction of terrestrial predators (black rats and feral cats) are thought to have led to its extinction.

The Hawaiian islands have lost a wealth of interesting species whose habits and niches we will probably never fully comprehend, and can only guess at. In the genus *Hemignathus* a number of species have vanished, including *H. vorpalis* and also *H. upuirostris*, a close relative. *H. vorpalis* (shown here) was the largest species in the genus, if not the largest in the family Drepanididae. This giant sported a greatly extended, curved upper mandible with which it probably probed into deep crevices for insects.

(*Emberiza cabanisi*) of Africa, and possessed longer legs and shorter wings. Like that species, it was a seed-eater, although in this particular case it was capable of feeding on the harder seeds characteristic of the island. *E. alcoveri* probably nested on the ground, in common with many island species where ground predators do not exist. It was this trait that led to the final demise of the species, when its island home was invaded by the first human colonists, who not only destroyed its fragile habitat, but also brought with them such exotic predators as cats and rats (Rando *et al.* 1999).

Among the other passerines, it is perhaps the Hawaiian honeycreepers that attract the most attention, firstly because of their extremes in bill shape, but also because their historical and prehistorical interactions with humankind make sober reading. Today, there are 23 species on the islands, but this is only what remains since the huge destructive forces of Polynesian and, later, European colonisation wiped out many of their relatives: one estimation suggests that as much as 64% of the native avifauna has disappeared from the Hawaiian islands to date. Some amazing adaptations existed among these 'pre-human' birds, and none more so than among the Drepanididae. For instance, the speciose genus *Hemignathus* has at least two additional species in the fossil record, one of which, *H. vorpalis*, was a giant (James & Olson 2003). *H. vorpalis* possessed an incredible, elongated upper mandible that the bird probably used to probe into deep crevices and sift through leaf litter to extract its insect prey. This bird became extinct on the island of Hawaii about 3000 years ago. A further 14 species of fossil and subfossil honeycreeper have so far been described, bringing the world's total up to 48; species are still being described (e.g. James 2004, James & Olson 2005). Several other species became extinct during European colonisation (see Fuller

World map showing some major sites for fossils.

1. **Solnhofen paleo-lagoons, Germany/Austria (Late Jurassic)**  
System of coastal lagoons important for the discovery of Archaeopteryx.
2. **Liaoning Province, China (Early Cretaceous)**  
Part of a vast region of northern China whose flora and fauna constitute the Jehol Biota. Sites within Liaoning and neighbouring areas provide the most comprehensive record currently known of an Early Cretaceous system—in this case a lacustrine/forest system. Famous, in particular, for its feathered dinosaurs and primitive birds.
3. **Lecho Formation, NW Argentina (Cretaceous)**  
Important site for the description of the Enantiornithes.
4. **Las Hoyas, Spain (Cretaceous)**  
Important site for the description of the Enantiornithes.
5. **Greensands, New Jersey, USA (Late Cretaceous/Early Paleocene)**  
Cretaceous / Early Paleocene birds.
6. **Green River Formations, SW Wyoming/SE Utah, USA (Lower Eocene)**  
Huge tropical lake system that underwent a similar change from fresh water to high salinity as that shown by the African Rift Valley.
7. **Messel, Germany (Eocene)**  
A site that provides a window on the flora and fauna near the beginning of the new diversification. Many of the species found in Europe from about this time suggest not only a direct link with North America, but also a possible land bridge with South America.
8. **Phosphorites du Quercy, France (Late Eocene to Late Oligocene)**  
Provides insight into the vertebrate fauna of the early Tertiary of Europe.
9. **Fayum Depression, Northern Egypt (Oligocene)**  
A site that provides one of the earliest and most complete records of the continental Tertiary flora and fauna of Africa.
10. **Riversleigh, NW Queensland, Australia (Miocene)**  
Important site for the window on Miocene Australia that it presents.
11. **Rancho La Brea Tar Pits, California, USA (Pleistocene)**  
Renowned for the variety of megafauna and scavenging carnivores that they have trapped.

2002), but whether this was due to European pressure or just the tail end of the original colonisation remains to be discovered. In reality, it was probably a mixture of the two, with the European influences putting the last nail in the coffin for many species, but causing the extinction of others that were still common. It is only recently that it has been realised how destructive the initial human colonisation of the Hawaiian islands was, and how diverse the original 'pristine' Hawaiian fauna had been.

### *Summary*

Although this overview has tried to be comprehensive in terms of the diversity of birds it has covered, the reader must be made aware that to do the subject justice would require far more space than can be given in HBW. Indeed, a whole book could be devoted to the subject (and many have been!). However, two features stand out above all the others. One is that of interpreting biogeographical patterns. Without the knowledge from fossils, what would our interpretation of such families as the swifts and nightjars been like? For instance, would we ever have discovered from other sources that hummingbirds used to be present in Europe? Probably not, although the discovery of nectarivorous birds in the European early Tertiary does clear up the little mystery of bird-adapted nectar plants, even if their presence was only investigated after the nectarivores were discovered. Also interesting in terms of biogeography is the closeness of the avifaunal assemblages of Europe and North America, which has provided the possibility that land bridges existed at various times between these two regions. The second feature that must stand out, other than the huge variety of bird forms that have existed, is the difficulty in interpreting those forms both phylogenetically and, even harder, in terms of habit and ecology. Although these latter can be tackled with educated guesses, we will never know for certain in the majority of cases what these birds ate, how they behaved, or even what they looked like in glorious technicolor.

New fossils are being discovered every day, or so it seems. While I have attempted to keep up with the most important of these, I know that I have not covered in any detail the relationships of the basal groups. As with any study, this article is already out of date before it has even gone into print, so please treat this as it should be—a celebration of the diversity that are the birds!

### *Acknowledgements*

I would like to thank Jane Cliff, Bob Deavin and Phil Harris for reading through the draft manuscript. I would also like to thank Gerald Mayr and C. David Polly for the help that they gave with respect to particular questions I encumbered them with, as well as Barbara Sinclair for translating some of the German citations, and Chen Zehang for her advice on the correct citation of the Chinese papers. I thank Frank Steinheimer for his thorough examination of the references, and the staff at Lynx, who have made writing this article a really pleasurable experience!

## Glossary

- Articulated fossil:** a complete fossil in which all the bones lie in the correct position, as they did when the animal died.
- Biogeography:** the study of distributions and ranges in organisms.
- Carinate:** of those birds whose primitive state involves the possession of a carina, or keel, on the sternal plate.
- Cladistics:** a philosophy of classification that arranges organisms only by their order of branching in an evolutionary tree, and not by purely morphological similarity. Thus, with cladistics, birds and theropods are placed together, whereas more traditional classifications would separate them.
- Cursorial:** of terrestrial animals adapted for speed rather than strength.
- Derived characters:** those which have evolved beyond the original form. For instance, the bill of a flamingo is highly derived from the standard 'generalist' bill morphology.
- Fossil:** the remains of a creature in which the bone and tissue have been replaced through a process of mineralisation, becoming rock-like in form. Trace fossils exist when tracks or faeces undergo a similar process. Particular environmental conditions must be met for fossilisation to occur.
- Furcula:** the 'wishbone', formed by the fusion of the two clavicles, or collar bones. Found in theropods, including birds.
- Genome:** the hereditary information encoded within an organism's DNA—its genetic make-up.
- Gondwana:** an ancient southern landmass encompassing what is now South America, India, Australia, New Zealand, Africa, Madagascar and Antarctica. Other continents were fused in a northern landmass, Laurasia.
- Graviportal:** megafaunal animals with massive bones and bodies, with columnar bones to carry weight; in consequence, their movements are restricted. Built for strength rather than speed in the first instance.
- Humerus:** upper arm/wing bone.
- Integuments:** hair, feathers, nails, skin, etc.—the natural outer covering of an organism.
- Jehol Biota:** consisting of the Yixian and Jiufotang Deposits, Early Cretaceous deposits from Liaoning, in the north of China. Famous for the discovery of *Confuciusornis*. Based on two different radiations of pterosaur, one group akin to that seen in the Late Jurassic of Europe, one to that seen in the Early Cretaceous of Brazil.
- Keel/Carina:** extension of the sternal plate on which the muscles of the wing are attached. In flightless species, this is often much reduced or even vestigial.
- K–T boundary:** Cretaceous–Tertiary boundary (from the German).
- Megafauna:** term used to encompass the giants of the fauna, e.g. elephant, rhino, ostrich.
- Mosaic species:** species in which characters of a variety of different groups are exhibited. Often, these mosaic species are basal examples before such groups split to become independent lineages.
- Mummy:** preserved specimens with flesh and integuments intact in such a way as that the organic material has not been replaced by rock minerals.
- Neoaves:** a taxonomic unit for all neognathous birds and including their ancestors, but excluding the Galloanserae.
- Neognath:** ('new jaw') any bird from the modern (neornithine) radiation that possesses the neognath palate. Among the neornithines, this excludes the tinamous, lithornes and ratites.
- Neotony:** retaining juvenile features into the adult phase of a life cycle, for instance the chick-like appearance of the adult ostrich.
- Osteology:** bone form; literally the study of bones.
- Palaeognath:** ('old jaw') a lineage of birds including the tinamous, lithornes and ratites. Palaeognaths and neognaths are distinguished by the anatomy of the palate.
- Pamprodactyl:** having all toes facing forwards, like the feet of a swift.
- Plesiomorphic:** primitive traits, found in the basal group and signifying an evolutionary lineage if found in more advanced species.
- Polyphyletic:** a taxon is said to be polyphyletic if the groups it contains possess different origins and come from different lineages.
- Pre-human birds:** birds that existed on islands prior to human colonisation. Most commonly used with reference to Pacific islands.
- Procoracoid:** the procoracoid bones lie posterior to the clavicles. They give support and stability to the pectoral girdle.
- Proto-feathers:** filamentous integumentary structures thought to be the precursors to true feathers. In reconstructions, often portrayed as hair-like or loosely structured.

- Pygostylia:** After Chiappe (1996), this includes all birds from *Confuciusornis* to Neornithes. The major characteristic of the group is the fusion of some or all of the tail bones into a solid structure, or pygostyle; this structure is not restricted to birds.
- Relictual distribution:** the distribution observed today, in which only part of an original range for the taxon in question is still occupied.
- Relictual species:** a species that is the last of its group, effectively a sort of living fossil.
- Saurischian:** 'lizard-hipped', including the sauropods (e.g. *Diplodocus*) and theropods. Birds originate from this group, rather than the other major dinosaur lineage, the ornithischian, or 'bird-hipped', group. The latter terms are essentially misnomers.
- Subfossil:** buried bones and tissue in which the mineralisation process has begun but is not complete.
- Switch-claw:** the enlarged claw of the inner toe of the Dromaeosauria and troodontids, usually held in a flexed position rather than flat on the ground like the other toes.
- Tarsometatarsus:** compound bone between the tibiotarsus and phalanges of a bird, formed by the fusion of the distal tarsal bones and the metatarsals.
- Theropods:** mainly bipedal carnivorous dinosaurs that include the ancestor of the birds (Aves). This grouping includes the Coelurosauria, among other groups. Characterised by thin-walled, hollow bones, hands and feet with three main fingers and toes.
- Tibiotarsus:** the large bone between the top leg bone (the femur) and the foot bones (tarsometatarsus) in a bird. Formed through the fusion of the long bone with the proximal bones of the ankle.
- Urvogel:** the earliest birds known, usually used in reference to *Archaeopteryx* and its closest relatives, if they are regarded as separate species.
- Vegetation mosaic:** a mixed zone in which patches of different habitat are intermingled with each other.
- Zygodactyl:** 'yoke-toed', in which two toes point forwards and two backwards (phalanges 1 and 4), as in a woodpecker.

## *Introduction to Volume 12*

This volume completes the large block of species and families formerly all lumped together in a broad version of Muscicapidae, a block that we first dipped into in Volume 10. We now move on to the tit/creeper section of traditional classifications.

The foreword in the present volume presents one of the subjects that has been most frequently requested by our readers, namely an account of fossil birds and their nearest relatives. We are very pleased to welcome Kevin Caley as our invited author. He offers a lively, new approach to the subject, and has complemented his extensive knowledge with an outstanding set of sketches drawn specially by himself.

With the arrival of the passerines, it has become increasingly apparent that for a number of families there is nothing of real relevance to comment under the Relationship with Man section. If authors are unable to find anything at all appropriate, rather than going through the motions we have decided to permit the exception of leaving this particular section blank. Nonetheless, we do hope that this will only be the case in relatively few families, for there are certainly others with a great deal of potential interest on offer.

For any readers who might be uncertain, we repeat brief definitions of a couple of terms that occur repeatedly in the Status and Conservation sections. As defined by BirdLife International, a "restricted-range species" is one which throughout historical times is reckoned always to have had an overall breeding range of under 50,000 km<sup>2</sup>. An Endemic Bird Area (EBA) is an area within which the overlapping breeding ranges of at least two restricted-range species are wholly encompassed. Following the figures published in recent years, restricted-range species account for some 27% of the world's avifauna, or about 2600 species, and these are restricted to about 220 EBAs, which in turn support roughly 75% of all globally threatened bird species. They are thus areas of high priority for conservation, all the more so as they tend equally to be centres of endemism for other life forms.

We have several assorted remarks to make on the subject of bibliography. These are of varying relevance for the present volume, for others to come, and for the series as a whole.

First of all, we have been delighted to welcome Dr Frank D. Steinheimer to the HBW team, to take over the important task of matters bibliographical. As a member of the Standing Committee on Ornithological Nomenclature, and a Research Fellow of the Museum für Naturkunde der Humboldt-Universität in Berlin, Frank is exceptionally well placed to contribute to the project. We are particularly grateful to the museum for allowing Frank to use its many resources for his work with HBW.

In all the volumes to date, whenever there has been any doubt about any aspect of an original description our aim has been to examine the original work ourselves, or have it checked by one of the several experts who have so kindly and freely given us their assistance time and again. We have never before quantified this process, but for the present volume we are in a position to present figures, in case these might be of interest to any readers. The 1020 references of original descriptions presented here are mainly based on the information given in J. L. Peters's *Check-list* (vols 10–12: 1964, 1967, 1986), out of which 465 entries have been checked for correctness by the HBW team; an annotated list has been kept of which descriptions have been seen as originals. Anyone in doubt with regard to any reference is invited to address the query to us (lynx@hbw.com).

In addition, we have a couple of short notes in connection with particular references:

**Lesson** (1835). *Oeuvres Compl. Buffon* 9: 139 [*Mohoua*]. This reference is copied from Mayr (1986b). We have been unable to confirm this original description and have only located a reference to the new genus *Mohoua* from **Lesson** (1838). *Compléments de Buffon*, 2nd edition, 2: 529.

and

**Oustalet** (1876). *Bull. Soc. Philom. Paris Ser. 6, no. 13*: 92 [*Dryonastes berthemyi*]. Deignan (1964b) and Dickinson (2003) are followed here for the citing of the publication dates. *Bull. Soc. Philom. Paris* was published in an irregular order, and will be subject of a forthcoming paper (Edward Dickinson, *in litt.* 6 June 2007).

While on this subject, we feel that it would be appropriate to acknowledge the great value for us of the Howard and Moore *Checklist* 3rd edition (2003). This major contribution has already picked up on a great many of the uncertainties emanating from the Peters *Check-list* combined with taxonomic developments, and the editor, Edward Dickinson, is always quick to resolve any issues upon which we have consulted him.

Readers are reminded once again that HBW Bibliography sections are not solely a collection of the source documents consulted, but also include an element of "suggested further reading". Thus, although 95–100% of the literature cited will have been consulted, there remains a small element of references which we believe may be useful for the reader looking to go into greater detail, but which neither authors nor the editorial team have consulted. It should perhaps be stressed that large reference works containing so much material that they might significantly add to the content of the text are only cited if they have indeed been consulted.

The present volume is the first in which we have included references from the Internet. We were at first somewhat hesitant, in part due to the very variable quality of material to be found on the Web, and also to the potentially transitory nature of some of it, but if treated with care, there is a great deal of useful information exceptionally accessible to the majority of readers, so we have now decided to permit such references, with appropriate caution.

And finally, we have a short note with regard to Chinese names. As these are, of course, necessarily transliterations, there is always the chance of some variance in spelling, when using the Roman alphabet. We have come across cases of the same author being cited using different transliterations in different publications, with the result that the same author can turn up under different names even within a single Bibliography section. In the end it seemed to us that it would cause more confusion to unify such names throughout our bibliography, as this would mean that readers might find themselves looking for, or even ordering, an article that actually appears under a different name. At the same time, we can not be sure that we would detect all such cases anyway. We beg understanding from anyone implicated, and sincerely trust that nobody feels in any way ill-treated.

### Acknowledgements

We thank the British Museum of Natural History at Tring (Robert Prys-Jones, Mark Adams, Katrina Cook, Jo Cooper, Alison Harding, Douglas Russell), the American Museum of Natural History in New York (Paul Sweet, Peg Hart, Shannon Kenney, Mary LeCroy), the Smithsonian Institution, National Museum of Natural History in Washington (James Dean), the Peabody Museum at Yale University (Kristof Zyskowski), the Natuurhistorisch Museum at Leiden (René Dekker, Hein van Grouw, Caroline Pepermans), the Australian Museum in Sydney (Walter Boles, Jaynia Tarnawski), the Field Museum in Chicago (David Willard, Mary Hennen), the Museum of Comparative Zoology at Harvard University (Jeremiah Trimble), the Bernice P. Bishop Museum in Honolulu (Carla H. Kishinami, Myra McShane) and the Museum Victoria (Wayne Longmore).

For the checking and editing of the bibliographies and scientific descriptions, libraries and their online catalogues have been particularly helpful, especially the Museum für Naturkunde in Berlin, the British Museum of Natural History at Tring, Deutsche Ornithologen-Gesellschaft in Berlin, the Muséum National d'Histoire Naturelle in Paris, the American Museum of Natural History in New York, the Library of Congress in Washington, the British Library in London, and the Preußische

Staatsbibliothek in Berlin. At the same time, we should like to compliment the extremely useful on-line taxonomy resource ([www.zoonomen.net](http://www.zoonomen.net)) maintained by Alan P. Peterson in Walla Walla, Washington.

The following individuals gave most generously of their help in a variety of ways, from supplying unpublished information and answering queries, to refereeing texts, proofreading foreign-language references and sending details about references. We are most grateful to Rune Aae, Norbert Bahr, Neil and Liz Baker, Bas van Balen, Brian Blaylock, Walter Boles, Murray Bruce, Stuart Butchart, Peter Cale, Brian Coates, Melody Cuthbert, René Dekker, Mary DeJong, Edward Dickinson, Bob Dowsett, Françoise Dowsett-Lemaire, Guy Dutson, Jon Fjeldså, Clifford and Dawn Frith, Diego Gil, Matthias Glaubrecht, Héctor Gómez de Silva, Michaela Handel, Louis Hansen, Alison Harding, Anabel Harries, Graeme Hyde, Mikhail Kalyakin, Ben King, Guy Kirwan, Wy Lo, Gerald Mayr, David Moyer, Storrs Olson, Jan Roger van Oosten, Ursula Peter, Alan Peterson, Steve Pryor, Christiane Quaiser, Hans-Ulrich Raake, Craig Robson, Svenja Sammler, Richard Schodde, Kristen M. Snyder, Carlo Violani, David Wells, James Alan Wolstencroft and Zhonghe Zhou. We are particularly indebted to Alice Cibois for her advice, especially on the complicated babbler section. Our special gratitude, too, goes to Normand David, who painstakingly checked through all the genus- and species-level taxa in the volume, both for gender agreement and for correct spelling. And last but by no means least we gratefully thank Guy Tudor and Michelle le Marchant for continuing to make available to us a wide array of photographs, which always prove most useful in preparing the plates.

As ever, we are most fortunate to receive prompt and full assistance in the business of supplying and updating the lists of French, German and Spanish names. We thank Normand David, Peter Barthel, Christoph Hinkelmann, Renate van den Elzen and Frank Steinheimer, and Eduardo de Juana, together with all their respective associates.

The individual authors and artists of this volume would like to extend their warm thanks to Mark R. Adams, B. Anderson, M. Andrews, John S. Ash, Ramana Athreya, Raffael Aye, Norbert Bahr, Bas van Balen, Mark Beaman, Mark van Beirs, David Bishop, Walter Boles, N. Bostock, A. Boto, A. Bräunlich, Tom M. Brooks, S. Buckton, Alan Burbidge, Reto Burri, Peter Cale, John Cantelo, Peter Capainolo, G. Carey, Hugh Chittenden, J. H. Christensen, Les Christidis, Alice Cibois, Peter Clement, Brian Coates, S. Comer, S. Connop, Katrina Cook, Jo Cooper, A. Crossland, P. Davidson, James Dean, Edward Dickinson, Eric Doerr, Veronica Doerr, C. Dranzoa, J. W. Duckworth, Guy Dutson, J. C. Eames, Chris Eastwood, T. D. Evans, G. D. Field, Lincoln D. C. Fishpool, Jon Fjeldså, I. S. Francis, Paul French, M. Germain, F. Goes, Martin Goodey, A. Graham, Sue Gregory, Anina Hainsworth, Mehd Halouate, Alison Harding, Anabel Harries, P. Heath, N. Hewston, P. I. Holt, Jon Hornbuckle, O. F. Jakobsen, J. Jansen, S. Jensen, E. Jirle, K. Kazmierczak, Robert S. Kennedy, Shannon Kenney, Guy Kirwan, Frank R. Lambert, Leoné Lemmer, R. Lewthwaite, Wayne Longmore, Michel Louette, Gary Luck, Clive F. Mann, Rodney Martins, H. L. Mays, Alan McBride, G. Morris, Janette Norman, Richard Noske, Rory O'Brien, S. Olson, T. Palliser, Park Eun-Mee, Park Jin-Young, E. Pasquet, John Penhallurick, Christopher M. Perrins, Robert Prys-Jones, Andy Radford, James Radford, M. Rank, Pamela C. Rasmussen, Sushma Reddy, Frank Rheindt, Nate Rice, A. R. Ridley, G. Riley, A. Robertson, C. S. Roselaar, Tobias Roth, Philip D. Round, Rose Ann Rowlett, Douglas Russell, Roger Safford, P. Sasirat, J. Scharringa, Holger Schneider, Manuel Schweizer, Derek Scott, D. Showler, Fiona Simpson, D. Stewart, S. Supparatrikorn, Paul R. Sweet, R. Timmins, Colin Trainor, Uthai Treesucon, R. Tymstra, J. van der Ven, Dominique Verbelen, E. Vercruysse, T. Wachter, Richard Webster, D. Wells, Jan Wilczur, Roger Wilkinson, M. Woodcock, Jo Wrigley, C. Yeung and Kristof Zyskowski, as well as the American Museum of Natural History in New York, the British Museum of Natural History at Tring, the Museum Victoria in Melbourne, the Peabody Museum at Yale University, the Philadelphia Academy of Natural Sciences, the Royal Society for the Protection of Birds, and the Smithsonian Institution, National Museum of Natural History in Washington.

And once again, for their assistance in a wide variety of ways, we should like to thank M<sup>a</sup> Josep de Andrés, Dolors Buxó, Juan Antonio Cantí, Cam Christie, Remko van Doorn, Marc Duquet, Marta Fenollar, Fortunato Frías, Rosa Llinàs, Albert Martínez-Vilalta, Isabel Martínez, Rafael Martínez, Anna Motis, Mary and Jim Ramsay, Olga Rius, Jamer Rivera, Iván Teba, Virginia Toledo and Aurea Vilalta. And what can we say about Toni Llobet, who graciously continues to embellish the back cover with his fine illustrations? Thank you!

## Class AVES

## Order PASSERIFORMES

## Suborder OSCINES

## Family PICATHARTIDAE (PICATHARTES)

- Relatively large passerines with long, broad tail, disproportionately large bill, relatively long and muscular legs; plumage dark above and whitish below, with bare skin of head brightly coloured.
- 33–38 cm.

- West and western Central Africa.
- Rainforest, extending into farmbrush and second growth.
- 1 genus, 2 species, 2 taxa.
- 2 species threatened; none extinct since 1600.

## Systematics

The family Picathartidae comprises a single genus with just two species, the White-necked Picathartes (*Picathartes gymnocephalus*) and the Grey-necked Picathartes (*Picathartes oreas*). Both are restricted to the rainforest belt of West and Central Africa. The former ranges from Guinea and Sierra Leone east to Ghana, and the Grey-necked Picathartes occurs in south-east Nigeria, west and south Cameroon, Equatorial Guinea, including Bioko, and Gabon, with one record in PR Congo.

The systematic position of the picathartes has been the subject of long-running controversy. The genus has been variously placed with the crows (Corvidae), the starlings (Sturnidae), the Old World flycatchers (Muscicapidae), the babblers (Timaliidae) and the Old World warblers (Sylviidae). It is now accorded separate family status by most authorities, and is usually positioned near the thrush-babbler assemblage.

In the late nineteenth century, in the earliest attempts to classify *Picathartes*, taxonomists placed the genus in the family Corvidae. This original view was subsequently supported by various authorities, including D. A. Bannerman, in 1948, and W. Serle, in 1952. After having seen the species alive, Bannerman gave *Picathartes* a family of its own, Picathartidae, which he placed next to Corvidae. Serle noted that *Picathartes* eggs were corvine-like, and that there was "remarkable similarity" in form and proportion between *Picathartes* and the Rail-babbler (*Eupetes macrocerus*) of the Malay Peninsula, Sumatra and north Borneo.

In 1938, P. R. Lowe removed the picathartes from the Corvidae and incorporated them as a subfamily, Picathartinae, in the Sturnidae, a decision based on anatomical examination of preserved *Picathartes* specimens. C. W. Mackworth-Praed and C. H. B. Grant followed this classification in their 1973 treatment of the birds of the western parts of Africa.

J. Delacour and D. Amadon had concluded that *Picathartes* had far more in common with the babblers than it had with the starlings, the crows or other passerines. From a review of the birds' behaviour, and examination of internal anatomy, they suggested, in 1951, that the genus was an aberrant member of the thrush-babbler assemblage which should be included as a sixth tribe, the Picathartini, in the subfamily Timaliinae within the family Muscicapidae. This view, that *Picathartes* was a close relative of the babblers, gained wide support from various researchers until the 1980s. During the 1970s, supporters included C. G. Sibley, who undertook comparative electrophoretic studies of the

patterns of egg-white protein, B. P. Hall and R. E. Moreau, who based their opinion on the available anatomical and behavioural evidence, and S. L. Olson, whose comparative studies included habitat, behaviour and morphology. The closest living relatives of *Picathartes* were thought probably to be members of the African timaliid genus *Turdoides*. The one discordant voice in this period was that of K. E. L. Simmons, who in 1963 pointed out that, unlike most babblers, *Picathartes* scratched its head by the indirect method, by bringing the foot over the wing.

Sibley and colleagues, in their 1988 classification of the living birds of the world based on the results of DNA-DNA hybridization studies, initially placed *Picathartes* with the babblers in the tribe Timaliini within the family Sylviidae, which was deemed to belong in the "parvorder" Passerida. In work published two years later, however, Sibley and B. L. Monroe included the genus in a full family in the limbo of "Parvorder *Incertae Sedis*", on the boundary between the Corvida and the Passerida. It was felt that, on the available DNA evidence, it was impossible to determine whether *Picathartes* was a member of the Corvida or of the Passerida. These authors cautiously speculated, however, that the rockjumpers of South Africa, the genus *Chaetops*, could be the closest relatives of *Picathartes* and that the lineage of the two genera may have branched from that of the other Corvida soon after the divergence between the Corvida and the Passerida. A consideration of anatomical evidence, specifically the structure of the humerus, in addition to DNA comparisons, led the authors to believe that, on balance, *Picathartes* was probably a member of Corvida. A recent study by S. Treplin & R. Tiedemann, using retrotransposon insertions as phylogenetic markers, goes further and supports a close link with the family Corvidae itself.

Analysis of DNA sequences in blood samples by H. S. Thompson, however, suggested that *Picathartes* is more closely related to the Passerida than to the Corvida. This is contrary to the tentative conclusions of Sibley and J. E. Ahlquist, in 1990, that *Picathartes* is a member of the Corvida, but it accords with the traditional views of Delacour and Amadon, among others, that the taxon is related to the thrush-babbler assemblage. The debate continues, as the databank continues to grow.

## Morphological Aspects

The two picathartes are beautiful, bizarre-looking birds with a bare brightly coloured head. In appearance, they look like a cross

The two members of Picathartidae are unmistakable birds of the West and west Central African forests. The **Grey-necked Picathartes** is almost entirely bald, with a few minute erectile crest feathers, a carmine nape, a powder-blue forecrown, and black parietal patches on the face. The taxonomic position of the family is unclear. It is believed by some to be related to the babblers (Timaliidae), and perhaps closest to the rockjumpers (Chaetops), although recent work suggests a possible close link with the crow lineage.

between a gamebird (Galliformes) and a crow, and they cannot be mistaken for any other species. Weighing about 200–250 g, these large birds are grey-brown or blackish in plumage above and whitish below. The skin of the bare head, including the nape, of the White-necked Picathartes is yellow, whereas that of the Grey-necked Picathartes is carmine on the hindcrown and nape and powder-blue on the forecrown. Two conspicuous black parietal patches form a black triangle on each side of the head, almost meeting at the back of the head. The bald crown bears a minute erectile crest consisting of a few tiny feathers, 6–8 mm in length, that are visible only at very close range when the bird is in the hand. A disproportionately large crow-like black bill, about 30 mm long, dominates the head, and indeed one of the alternative English names for these species is “bald crows”, a term not entirely inappropriate. The silver-grey legs are relatively long and muscular, well suited for the usual mode of progression of picathartes, which is by a series of surprisingly graceful hops and bounds along the forest floor.

Sustained flight by these species is rare, although the wings are moderately sized. The long, broad tail, considerably longer than the body, is frequently used as a means of maintaining balance on vines and branches.

Close examination of the plumage shows that the whitish ventral feathering of the White-necked Picathartes is washed with pale lemon-yellow, grading into pale yellow on the throat and upper belly. The Grey-necked Picathartes has a grey wash on the throat and chest. Its dorsal side is slate-grey, as opposed to the grey-brown of the White-necked Picathartes, and the primaries form a very distinctive black band separating the slate-grey of the back from the yellowish colour of the vent.

The sexes are alike, with no evident differences between them in plumage, eye colour and leg colour. Of 25 White-necked Picathartes examined in the field, all had the pupil blue-black and the iris brown, and Thompson found the body mass of this species to be 192–254 g, with an average of 219.2 g. Mean adult body measurements for the bill, the tarsus, the wing and the tail were, respectively, 33.1 mm, 63.8 mm, 163.8 mm and 182.8 mm. Six adult Grey-necked Picathartes weighed by C. G. R. Bowden in the 1980s had an average mass of 226.5 g, the lightest being 202 g and the heaviest 239 g. Measurements of eleven museum skins of this species were similar to those of live White-necked Picathartes measurements but slightly smaller, probably as a result of shrinkage; for the Grey-necked Picathartes, the average lengths were 37 mm for the bill, 49.4 mm for the tarsus, 158.3 mm for the wing and 155.2 mm for the tail. Museum-skin measure-

ments further suggest that Grey-necked Picathartes males are larger than the females, this sexual size difference being most detectable in the tarsal measurements.

Comparison of museum skins of the two species, made by Thompson, indicate that the White-necked Picathartes is larger in size than the Grey-necked Picathartes, but that the latter has a larger bill.

## Habitat

Typical habitat for picathartes is lowland rainforest at up to 800 m in elevation, in rocky, hilly terrain on the slopes of hills and mountains. Hill slopes with nesting sites of these species are usually inclined at an angle of 20°–49° to the horizontal, and normally less than 100 m from running water in the form of rivers and streams, as wet mud is essential for the purposes of nest-building. The presence of inselbergs makes the occurrence of these birds more likely. Rocks, cliffs or caves are required for nesting sites, and forest litter and undergrowth for foraging. In addition, a forested area large enough to contain army-ant (Dorylinae) swarms is more likely to harbour picathartes, too.

Picathartes habitat has traditionally been regarded as being remote from human habitation, and fairly undisturbed. In the 1990s, however, members of this family were recorded in more disturbed habitats, such as forest clearings, farmbrush and secondary growth. For example, a comprehensive survey of White-necked Picathartes colonies in Sierra Leone, carried out by Thompson, revealed that, although 70% of colonies were in secondary forest, a substantial number, 20%, were in farmbrush or forest regrowth; primary forest and cocoa plantations each held 5% of the total of 56 colonies found. Detailed habitat analysis showed that nesting sites abandoned by picathartes had lower tree densities, smaller trees and less canopy cover than did sites which were still used for breeding. This implied that habitat degradation probably caused the birds to move away from what were previously suitable nesting sites. On the other hand, picathartes have been found breeding also at sites quite close to human activity, such as less than 30 m from a maize (*Zea mays*) plot in Cameroon and 50 m from a charcoal-production pit in Sierra Leone, as well as in forest regrowth where complete forest cover was lacking. This suggests that the family is tolerant of fairly high levels of disturbance and that it can continue to exist in highly degraded habitat. It also calls into question the extent of the two species' dependence on forested habitat for survival.

## General Habits

Picathartes are rare forest-dwelling species. Compared with many other rainforest birds, they are relatively hard to see, partly because their populations are small and the breeding habitat is usually fairly inaccessible. For the most part, however, their quick and silent evasive reaction to any untoward movement or sound means that a human observer has to be extremely lucky to detect them away from their breeding sites. Nevertheless, once located by a cautious and quiet observer, or when at a breeding colony, the picathartes can be quite bold and confiding, even coming to inspect the observer. In 2006, E. Williams described how he was surrounded by "hissing and growling birds" at what is probably the world's largest Grey-necked Picathartes colony, that in the Dja Forest, in Cameroon.

Away from breeding colonies, these species are almost always encountered in primary or secondary forest, usually singly or in pairs, but occasionally in small groups of three or four individuals. They spend most of their time in foraging on the forest floor or on low vegetation, usually not more than one metre in height, although the Grey-necked Picathartes has been reported as occasionally hunting among bat guano in the caves where it breeds. Picathartes are frequent followers of columns of carnivorous ants, and are often found at these columns while foraging for flushed prey. Occasional sightings in forest clearings, in farmbrush and in forest where manual tree-felling is taking place suggest that these birds may range over a fair-sized area, utilizing non-forest habitats to a certain extent, and that, as mentioned above (see Habitat), they may not be over-sensitive to low levels of disturbance.

At breeding sites, several individuals may be seen at dawn or dusk throughout the year. Picathartes make regular visits to their nesting sites even outside the breeding season, and may roost in the vicinity in all months of the year. Typically, several birds congregate at a nesting site in the evenings and then leave at dusk, heading in different directions, singly or in pairs, to roost in nearby trees. While at the nesting site, the birds engage in various activities, such as nest-repairing, perching on nest rims, hopping about, preening, bathing, foraging and chasing one another. Allopreening has been observed, but it appears to be rare in this family.

Occasionally, as the egg-laying period approaches, chasing escalates into a peculiar group interaction involving pursuit sequences and a bowing display. In the latter display, an individual, while facing one or more others, makes a deep bow during which it holds the wings fully or partially raised, the effect being to present the coloured crown and black ear patches at the other bird or birds in the immediate vicinity. Each bow is usually followed by feather-ruffling and tail-shaking. The significance of this behaviour is uncertain, and it has been described variously as "peculiar individual behaviour", a "formalized display associated with roosting or breeding", "pre-group-roosting-intention display" and "group interaction behaviour associated with breeding".

## Voice

Both species of picathartes are usually silent, but they are known to make a variety of calls in different contexts, including the following.

When disturbed or threatened, the individual utters an alarm call. That of the White-necked Picathartes is a long drawn-out "aaoww", "kaaa" or "raaa" and is surprisingly loud. The alarm call of the Grey-necked Picathartes is also long and drawn out, but somewhat more muffled; it has been described by I. Sinclair and P. Ryan as "soft, protracted and sibilant".

Churring sounds are emitted by group-members during gatherings prior to roosting or breeding. These have sometimes been described as "hissing and growling".

A melodious whistling is used as a contact call between fledglings and adults of the White-necked Picathartes as the former leave the nest. In addition, an "owoooh" contact call between fledglings and adults is sometimes used as an alarm call by the adults.

The White-necked Picathartes differs from its sole congener most notably in having the bare skin on its head yellow. Both Picathartes are rare and elusive, and very difficult to see away from their breeding colonies. These colonies are found deep in rainforest, but also in secondary forest and partially degraded areas close to agricultural fields and human settlements.

[Picathartes gymnocephalus, West Africa. Photo: Kevin Schafer/ NHPA]

Grey-necked Picathartes sometimes emit a low, quiet drawn-out rasping or hissing "wheet" call lasting 1–2 seconds, generally repeating this several times at intervals of approximately four seconds. This vocalization is probably the same as the call which has been likened to the sound made by "heavy furniture being pushed across a gritty wooden floor".

Finally, the White-necked Picathartes has been described as uttering evenly spaced clucks in a series lasting for a minute or more. These sounds resemble those given by a domesticated chicken (*Gallus*), and are given at rates varying from four in 3 seconds to eight in 5 seconds. It has been suggested that this vocalization may possibly represent a song, but further study is required in order to elucidate this.

## Food and Feeding

The food of the picathartes is dominated by insects and other forest-floor invertebrates. Beetles (Coleoptera), termites (Isoptera) and ants (Hymenoptera) seem to be the most commonly occurring insect prey among identified items in the diet, while the other invertebrates taken are primarily earthworms (Oligochaeta), millipedes (Diplopoda) and centipedes (Chilopoda). In addition, small vertebrates in the form of frogs and lizards are taken, but most, if not all, of these appear to be presented to the nestlings. Within these broad parameters, however, the picathartid diet seems, on the whole, to be fairly diverse and generalized, with more than 25 other prey categories identified, including spiders (Araneae), crabs (Decapoda), snails (Gastropoda), and ticks and mites (Acarina). Some plant material, chiefly of angiosperms and mosses, is occasionally consumed.

Detailed analyses of stomach contents undertaken by several ornithologists, direct observations by H. Tye, faecal analysis by Thompson and, most recently, crop-content analysis by A. I. Adeyemo and I. A. Ayodele have all revealed insects as being numerically the main constituents of the picathartes diet. In these studies, the predominant insect prey were beetles of such families as Carabidae, Scarabaeidae, Elateridae, Anthribidae, Curculionidae and Staphylinidae, cockroaches of the family Blattidae, orthopterans of the family Tettigoniidae, earwigs of the family Forficulidae, termites of the family Rhinotermitidae, *Dorylus* ants, heteropteran bugs, and butterflies and moths (Lepidoptera).

Although insects dominate the diet in terms of prey diversity and numerical abundance, earthworms and small vertebrates seem to be the most important food resources in respect of biomass, at least for the nestlings. In a study carried out in Sierra Leone in the 1990s, it was found that more than 80% of the biomass in the diet of White-necked Picathartes nestlings was made up of earthworms, frogs and lizards.

The fact that the picathartid diet contains such items as carabid ground beetles and earthworms, coupled with direct observations in the field, indicates that these two species forage mainly on the

soil surface and in low undergrowth. Nevertheless, Adeyemo and Ayodele, on the basis of their study in Nigeria, described the Grey-necked Picathartes as an arboreal feeder. In addition, however, it is evident that picathartes occasionally forage in flowing water, such as streams. This is indicated by the fact that crabs found mainly in streams have been identified in White-necked Picathartes droppings, and fish have been found in the crops of Grey-necked Picathartes caught near a Nigerian river.

On the ground, these species normally move in series of long bounds and graceful hops interspersed with pauses. The bill is the primary foraging tool, used for turning over and tossing aside leaves and for capturing prey. The feet are hardly ever used for acquiring food. Both species also leap upwards to snatch prey from foliage.

Both members of the family are known to follow swarms of carnivorous doryline ants (see General Habits), where they frequently forage ahead of or among the ants. As with the majority of ant-following bird species, however, this is mainly in order to capture prey flushed by the ants.

In conclusion, the two picathartes species seem to have a fairly diverse, generalized diet. This could confer a high degree of adaptability, enabling them to exploit different prey items if their preferred food became scarce or unavailable. An unspecialized diet is often associated also with a widespread distribution and rapid colonization of new environments. This suggests that the restricted range of the genus and the apparently small size of the populations of the two species are not related to their ability to find food.

## Breeding

Both species of picathartes generally breed in the wet season, apparently nesting twice per year in areas where rainfall distribution is bimodal. In fact, eggs and nestlings can be found in any month of the year, partly because wet seasons occur at different times in different parts of the species' ranges but also because, in montane areas, breeding takes place in the dry season. This is

known to be the case on Mount Nimba, in Liberia, and on Mount Cameroon. This habit of dry-season breeding may have been adopted because of the very high rainfall and frequent mists during the wet season at high altitude, a factor which is known to constrain wet-season breeding severely among montane birds.

The breeding season of the White-necked Picathartes in Guinea is July–January. In Sierra Leone, the laying period extends from June to December, with a peak in October, and nestlings can be found from August to January, with highest numbers in November. Laying dates in Liberia cover the period September–December, the majority falling in October, with a second period in March, May and July; here, laying in the dry-season months of December and March may be explained by differences in timing of breeding at high-altitude locations such as Mount Nimba. Breeding has been recorded in March, April and May in Ivory Coast and in March–June and September–November in Ghana.

Somewhat farther east, the Grey-necked Picathartes has been recorded as breeding in August–November in Nigeria. On Mount Cameroon, this species breeds in the December–January dry season, but elsewhere in Cameroon nesting takes place in March–November, with a peak between August and November. The breeding season in Gabon is November–April, whereas there are as yet no documented breeding records of the species from Equatorial Guinea or from PR Congo, although it seems unlikely that the details would be substantially different from those elsewhere in the range.

Very unusually for a rainforest bird, *Picathartes* builds mud nests on rock surfaces, cliffs and cave roofs, hence the popular alternative name of “rockfowl”. Most rock surfaces selected by the two species slope forwards at an angle of at least 10°–20°, or the nest is built below an overhang or rock pelmet, presumably to afford protection from rain and water run-off. Nests have occasionally been found in unusual places, as, for instance, in 1999, when M. Waltert and M. Mühlenberg discovered a Grey-necked Picathartes nest attached to the buttress root of a large *Piptadeniatrium* tree 1.5 m above ground near a small forest stream.

**The Grey-necked Picathartes** was once thought to breed cooperatively, but it now seems clear that it is socially monogamous. The female typically lays two eggs, although less often clutches may be of one or three eggs. The nest is decidedly peculiar: a cup-shaped structure made of dried mud packed with leaves, plant fibres and twigs. Both Picathartes are very particular about where they put these nests, almost always attaching them to overhanging rock surfaces, cliffs and caves, presumably to afford protection from rain. They often nest colonially, with the largest known colony of Grey-necked Picathartes, at Dja in south Cameroon, containing over 40 pairs.

[*Picathartes oreas*,  
Korup National Park,  
Cameroon.  
Photo: Ketil Knudsen]

Picathartes nests are cup-shaped structures of dried leaves, fibres and twigs embedded in a strong matrix of dried mud. Sixty-three nests of White-necked Picathartes had average measurements of 108 mm in length, 172 mm in width and 129 mm in depth, but individual sizes varied by as great a factor as six for some dimensions. There is similar considerable variation in the size of Grey-necked Picathartes nests, but R. M. Bian and colleagues gave the measurements of a typical nest as 400 mm long by 290 mm wide and 140 mm thick.

Breeding by these species is usually described as colonial, with up to 40 or more pairs of Grey-necked Picathartes recorded at a single nesting site, as, for example, in Dja Forest, in Cameroon. A review of 37 White-necked Picathartes sites in Sierra Leone in the 1990s, however, found that most contained only one or two nests, the maximum number at one site being eleven. The mean colony size was 2.27 nests. Of a total of 78 nests, the majority, 68%, were 1.5–2.5 m above the ground, and more than three-quarters were spaced at 1–1.5 m from the nearest neighbour. Grey-necked Picathartes are thought to breed colonially where nest-sites are limited, the majority of colonies consisting of two to five nests, but this species is not a colonial breeder on Mount Cameroon, where nest-sites are abundant, and it possibly does not breed in colonies at all on Bioko. Six nests found by Tye on Mount Cameroon were all solitary, rather than in colonies, with no other nest within 400 m of an active nest.

Contrary to some early suggestions of co-operative breeding, it is now almost certain that picathartes breed only in pairs. Pairs of White-necked Picathartes are aggressive towards conspecifics which approach their nests to within less than a metre or so, and vicious fights sometimes occur. Outside the breeding season, at least, groups of 6–12 individuals sometimes gather at roosting sites and engage in group displays involving chases and bowing, as described earlier (see General Habits). It is uncertain whether these displays have any connection with breeding.

Picathartes usually lay two eggs in the wet season, but sometimes one or three eggs may be laid. Of 77 White-necked Picathartes clutches examined in Sierra Leone, 71 were of two eggs and only six contained a single egg; the mean clutch size was of 1.92 eggs. Similarly, only one of 16 clutches laid by Grey-necked Picathartes in a west Cameroon study was of one egg, the remaining 15 all consisting of two eggs.

Measurement of 47 White-necked Picathartes eggs produced an average size of 25.8 mm × 38.3 mm, with a range of 20–28 mm × 30.4–42 mm. The mean weight of freshly laid eggs was 14.5 g, which is equivalent to 6.6% of the mean adult body weight. In four clutches monitored, the eggs lost about 14% of their initial fresh weight during incubation, an average of 0.122 g per day. The weights and dimensions of Grey-necked Picathartes eggs are similar to those of this species' congener; four eggs from two clutches found about half-way through the incubation period in Cameroon weighed from 14.7 g to 16 g, and their sizes were 27–28 mm × 39.6–41.7 mm. Grey-necked Picathartes eggs are apparently quite variable in appearance. They have been described variously as pale grey with brown mottling, as dark fawn with dark brown blotches, and as creamy white with blotches and/or spots of chocolate-brown, olive-green or grey; another description is "pale green with a deep layer of grey spots and a superficial layer of olive-green spots". White-necked Picathartes eggs are much less variable, most being creamy white with sepia and dark brown mottled blotches and other markings, these usually denser at the larger end of the egg.

The eggs are laid 24–48 hours apart. The White-necked Picathartes begins incubation on the day when the first egg is laid, whereas the Grey-necked Picathartes is said to start incubating only when the clutch is complete. Estimates of the incubation period range from 17 days to 28 days, with a median of 20 days in the most quantitative study to date, that of six White-necked Picathartes nests. The parents take turns to incubate the eggs, which hatch at an interval of at least 12 hours. The nestling period at the six White-necked Picathartes nests ranged from 23 to 29 days, the average being 25.3 days. The nestling period of the Grey-necked Picathartes is evidently about 24 days.

On hatching picathartes nestlings are blind and naked, except for three to four bristles on the crown and a single row of

white down along the spine. Fine down may be present also in lines along the wing bones and the femur. The body is translucent pink below and light brown above, with black wing buds. The primary and secondary quills begin to grow about two days after hatching, and the tail feathers and tertials appear from days 5–7. The eyes open from day 4 or 5. The conspicuous black ear patches characteristic of adults (see Morphological Aspects) are nowhere to be seen on the hatchling, but they become distinct from about day 7 as light brown or flesh-coloured patches. At this stage, when the chick is about one week old, the bill is pale brown, almost yellow, instead of black, and it has a white rim around the edges of the mandibles. The legs are pale grey.

From about one week of age, the nestlings may start to make begging calls when adults approach the nest. From 8–10 days, they defecate over the side of the nest; before this stage, faeces are deposited in the nest, and the parents consume faecal sacs or remove them from the nest. During the second and third weeks of its life, the nestling's wing and tail feathers erupt from pin and grow rapidly, followed by the body feathers on all the main pteryxae (feather tracts). The bill is now black, with a yellow gape, and the ear patches are darker. Just prior to fledging, from day 23 onwards, the nestling closely resembles the adult in plumage, except for the head coloration. In the case of the White-necked Picathartes, the yellow head skin of the adult is already developed to varying extents at fledging, whereas the adult head colours of the Grey-necked Picathartes seem to be absent at fledging.

Chicks more than three weeks old regularly stand in the nest or climb on the rim to preen or to flap their wings. When about to leave the nest for the first time, young White-necked Picathartes whistle in a characteristic piercing manner, as also do their parents, and the chicks leave by gliding with outstretched wings from the nest rim to the ground, where they are met by an adult, which feeds them with insects before they are led away.

Nestling growth curves are sigmoidal, and body weights increase from about 11–12 g, equal to about 5% of mean adult weights, at hatching to about 150–160 g, approximately 70% of adult values, just before fledging. Other measurements, including those of the wing, the tail and the bill, exhibit a similar pattern, so that body size does not reach that of the adult during the nestling stage, growth being completed after the young leave the nest. The tarsus grows fastest of all and the tail is the slowest-growing, so that tail length at fledging is less than one third that of a mature adult.

Nesting success of White-necked Picathartes, defined as the probability of eggs laid surviving both the incubation and nestling stages, is currently low. Success levels have apparently declined, from 71% in Ghana in the 1960s to 23% in Sierra Leone in the 1990s. This decline over a period of 30 years may have come about as a result of increased disturbance or reduced habitat quality and/or availability. In Sierra Leone, the number of White-necked Picathartes chicks successfully reared per nesting pair in the 1990s was only 0.44. A theoretical predictive life-table model constructed from these data indicates that populations of this species in Sierra Leone could be declining slowly because of natural causes alone. An alternative possibility is that the White-necked Picathartes is very long-lived, with an adult survival rate in excess of 90%, and that there is strong competition for nest-sites, so that populations are self-sustaining so long as adult mortality remains low.

Known causes of nest losses suffered by picathartes are predation, infanticide or cannibalism, competition from intruding conspecifics, and infertile eggs. Predation seems to be the main cause, accounting for 41% of nest-content losses at 22 White-necked Picathartes nests in Sierra Leone. Many nests and their contents are lost or destroyed for unknown reasons. In studies in Sierra Leone, 36% of losses could not be assigned to any known factor with any degree of certainty. Infanticide or conspecific competition caused 14% of losses, while eggs which remained in the nest beyond the estimated maximum incubation period before disappearing were deemed infertile and these accounted for 9% of failures.

Predators of the two species of picathartes are thought to include snakes, such as the spitting cobra (*Naja nigricollis*) and the black-and-white cobra (*Naja melanoleuca*), monitor lizards (*Varanus niloticus*), forest sun-squirrels (*Heliosciurus*), forest

**The White-necked Picathartes** generally breeds in the wet season, perhaps because this is when mud nests are easiest to build, or because this coincides with peak prey abundance. Both parents incubate the eggs for some 20 days, and feed the nestlings for 25–26 days. The nestling diet includes large numbers of forest-floor invertebrates, including earthworms, millipedes, and insects such as grasshoppers and beetles. In terms of biomass, vertebrates such as frogs and lizards make up a major component of the diet.

[*Picathartes gymnocephalus*, Mount Nimba, Liberia. Photo: A. Forbes-Watson/VIREO]

raptors such as the Red-chested Goshawk (*Accipiter toussenelii*), colobine monkeys (*Procolobus*), chimpanzees (*Pan troglodytes*) and human beings. Hunters, young boys and chimpanzees are known to take eggs from nests or to destroy nests; snakes and monitor lizards have been flushed from breeding sites; and squirrels, raptors and monkeys elicit loud alarm calls from breeding pairs. Adult picathartes roosting in nests are sometimes killed by hunters, but this seems for the most part to be incidental. The apparent inaccessibility of most picathartes nests, sited 1.5–2.5 m above ground on largely smooth vertical rock faces, suggests that avian species, probably raptors, are the main predators. Predation by snakes is thought to be rare.

Infanticide by bird species has only rarely been documented, but it seems to be widespread among picathartes, having been recorded since the 1960s for both captive and wild individuals over most of the range of the genus in Gabon, Cameroon and Sierra Leone. In Sierra Leone, adults were observed as they removed eggs and/or chicks from two nests of conspecifics in the absence of the nest-owners, and on one occasion fighting with nest-owners to the extent that the nest was destroyed and the chicks killed. Infanticide has generally been explained as being variously exploitation, resource competition, parental manipulation and sexual selection.

Although picathartes have been described as egg-eaters in captivity, they have not been observed to eat the eggs or young of conspecifics in the wild, such behaviour having been, at best, inferred as occurring in Cameroon. Moreover, breeding pairs in Cameroon and Sierra Leone have been observed to defend their nests against adult conspecifics which were attempting, sometimes successfully, to destroy the contents. These observations indicate that adult picathartes, at least in the wild, do not consume or otherwise use their victims for their own benefit, as they would if exploitation were the correct explanation for the behaviour. Nor did they destroy their own young in order to improve their own chances

of survival or those of other, existing offspring, which they should have done if parental manipulation were the reason.

Thompson has suggested that the birds destroy one another's offspring in order to gain access to suitable breeding sites, which are known to be limited in some parts of their range. This explanation fits with observations which suggest that *Picathartes* is monogamous and that non-breeders or "floaters" occur at some breeding sites. Disturbance by floaters lowers the breeding success of some bird species, and it is possible that picathartes floaters destroy nests and their contents so as to gain access to nesting sites or mates.

## Movements

The two species of *Picathartes* are resident Afrotropical birds that do not undertake long-distance migrations. They were initially thought to stay close to the breeding/roosting sites throughout the year, but investigations in the 1990s suggest that they undertake localized movements over a wide area and make regular use of non-forested habitat, including clearings, farmbrush or forest regrowth, and along man-made tracks, paths and roads. A. Siaka estimated the home-range size of six White-necked Picathartes fitted with radio transmitters as varying from 0.322 km<sup>2</sup> to 3.92 km<sup>2</sup>, with a mean size of 1.36 km<sup>2</sup>; 82.5% of this home-range area comprised forested habitat, while 17.5% was farmbrush.

Very little more is known about the local movements of the picathartes. Because the species breed mainly in forest, and because this rainforest habitat is becoming increasingly fragmented, an essential question in picathartes ecology is that of whether adults and juveniles can disperse across significant chunks of non-forested habitat. This is not yet known, and the answer may well hold one of the keys to the future survival of the genus.

The **White-necked Picathartes** usually lays two eggs, but overall breeding success is apparently low. In Sierra Leone, one study concluded that only 23% of eggs laid produced fledglings and only 0.44 young fledged per pair. The causes of nest failure are many and varied, including infanticide and cannibalism, both of which seem unusually common in *Picathartes*. Nests are also preyed upon by raptors, reptiles and primates (including humans). The low reproductive output of *picathartes* is compounded by low population density and habitat fragmentation in West African forests. Both species are thought to number fewer than 10,000 mature individuals, both are thought to be declining, and both are classed as Vulnerable.

### Relationship with Man

In the past, *Picathartes* has had totemic value in parts of its range. In the south and east of Sierra Leone, for example, the imposing and sometimes bizarre-looking rock formations on which the White-necked Picathartes build their nests were once thought to house ancestral spirits, and the birds themselves were considered guardians of these ancestral homes. Although these beliefs are now largely extinct, a residual fascination with the birds has persisted, and local people are often reluctant to molest them or to destroy their nests. On the other hand, the inaccessibility of the terrain in which these species are usually found, coupled with their normally shy behaviour, has meant that their presence is often unknown to the vast majority of local human populations in areas where they exist.

Hunters and trappers are known to take eggs and young opportunistically, but almost certainly at very low levels when left to their own devices. In the 1950s and 1960s, however, demand from western zoos and bird-keepers fuelled a demand for live picathartes that almost certainly contributed to the recorded population reductions in the wild (see Status and Conservation). Thankfully, this trade has now largely died down.

Since the 1990s, *Picathartes* has become an iconic symbol and flagship taxon for conservation and eco-tourism in West Africa, holding an enduring interest for birdwatchers, tourists and scientific researchers because of its striking appearance, its strange habits and its rarity.

### Status and Conservation

Both species of picathartes are classified as Vulnerable under the IUCN/BirdLife threat criteria. The global population of each is thought to number fewer than 10,000 mature individuals, and it is likely that there will be a continuing decline in numbers of mature individuals of at least 10% within ten years. The Grey-necked Picathartes is almost certainly more common and more widely distributed than the White-necked Picathartes, and there is support from some ornithologists for its threat status to be downgraded from Vulnerable to Near-threatened.

In recent systematic problem analyses by Thompson and co-workers, in 2004, and Bian and colleagues, in 2006, it was determined that the current low estimated populations of picathartes stem from a reduction in the extent and/or quality of the species' preferred rainforest habitat, from declining population trends, from lack of knowledge of the species' distribution and numbers, and from naturally low population densities. Habitat destruction, particularly deforestation, and habitat fragmentation and degradation are the main reasons for the decline in the area of suitable habitat and the recurrent trend of declining population estimates. The proximal causes of the destruction and degradation of rainforest across the species' ranges in West and west-central Africa are numerous and complex, but are almost invariably related to unsustainable and poorly planned human-related developments. These include intensified and unplanned agricultural expansion for increasing human populations and settlement expansions, which in turn result in increased demands for energy, income, food and other human needs. These needs result in practices that have a negative impact on picathartes' habitats, such activities including: forest clearance for food cultivation; fuel-wood extraction; illegal logging; commercial logging; wood-cutting for poles; charcoal production; and so on. Natural disasters such as wildfires and landslides may also play a role in the reduction in the area of natural habitat available to the species.

Picathartes seem also to occur in naturally low population densities, and there is a lack of knowledge of their distribution and abundance in some parts of their ranges. It is now recognized that the inaccessibility of some of the breeding sites of the species, insufficient inventories, and inadequate research stemming from limited trained personnel and funds may be leading to underestimates of the species' true numbers and to estimates of declining population trend. Furthermore, some aspects of the breeding biology and ecology of picathartes may be promoting

the impression of "natural rarity". These include stringent physical parameters for breeding sites, resulting in shortages in suitable sites and competition for nest-sites, which lead to fighting among adults, infanticide, and egg and nest destruction (see Breeding). Incidental hunting and trapping may have contributed to the decline in population levels, and offtake for the cagebird trade perhaps had a somewhat more serious impact. This trade, however, is now mainly obsolete, because of greater awareness among local human inhabitants, stricter law enforcement and changing ethical perspectives.

Both picathartes species are listed in Appendix I of CITES and both are protected by national legislation in some parts of their ranges. The White-necked Picathartes receives legal protection in Sierra Leone, Liberia and Ghana and the Grey-necked Picathartes in Cameroon.

Various recommendations have been made for the conservation and management of the two picathartes, and "Species Action Plans" have been developed, by Thompson and colleagues for the White-necked Picathartes and by Bian and colleagues for the Grey-necked Picathartes, in an attempt to improve the conservation status of each one. The plans aim to stabilize or increase the populations of the two species in key range states within five years. In order to achieve these aims, a number of specific objectives and strategies are set out, of which the priorities are to ensure that realistic estimates of population size and distribution are available, that unsustainable human-related development and activities at major breeding strongholds are reduced measurably, and that local capacity for the study and conservation of the species is reinforced.

Under the aegis of BirdLife International, "International Species Interest Groups" have been formed to implement, and to monitor the effectiveness of, these action plans for the picathartes. The groups are co-ordinated both regionally and at national level. The plans were developed through a highly participatory process involving national and international experts, as well as government representatives, students and other interested parties, thus providing a training opportunity, and facilitating the formation of conservation networks and the incorporation of the plans into general national biodiversity-conservation frameworks.

The success of these Species Action Plans will depend on their being rapidly implemented and regularly reviewed. At the time of going to press, in mid-2007, components of the plans were being implemented by BirdLife partners in Sierra Leone, to protect breeding sites of the White-necked Picathartes in the Western Area Peninsula Forest; in Ghana, to update estimates of the national population size and distribution of that species; and in Cameroon, to safeguard breeding sites of the Grey-necked Picathartes at Mbam-Minkom, close to the capital city of Yaoundé. These are promising signs but, in the long run, the continued survival of picathartes populations in West and Central Africa will depend on the continued existence and holistic proper management of the Guineo-Congolian forest belt in which these two fascinating species occur.

PLATE 1

Genus *PICATHARTES* Lesson, 1828

1. White-necked Picathartes

*Picathartes gymnocephalus*

**French:** Picatharte de Guinée **German:** Gelbkopf-Felshüpfer **Spanish:** Picatartes Cuelliblanco  
**Other common names:** White-necked/Bare-headed Rockfowl, Yellow-headed Picathartes/Rockfowl

**Taxonomy.** *Corvus gymnocephalus* Temminck, 1825, Guinea coast.  
 Taxonomic position of genus subject to ongoing debate. Now generally considered to represent a monotypic family, related to “thrush-babbler assemblage” of the Timaliidae; has been suggested that closest relatives are the rockjumpers (*Chaetops*) of South Africa. May form a superspecies with *P. oreas*. Monotypic.

**Distribution.** Forest belt in S & E Guinea, Sierra Leone, Liberia, Ivory Coast and Ghana.

**Descriptive notes.** 33–38 cm; 192–254 g. Large unusual-looking passerine with fairly long and broad tail, large curved bill, strong and muscular legs. Most of head and nape are bare, with yellow skin, sharply contrasting black patch on rear side of head; upperparts, including wing and tail, mainly dark slaty to blackish with brown tinge (brownest in mantle region and tail); soft grey down feathers below contour feathers sometimes give upper surfaces a silvery sheen; white below, feathers tinged with pale lemon-yellow, grading into pale yellow on throat and upper belly; iris brown, pupil blue-black; bill black; legs sil-

ver-grey. Sexes alike. Juvenile resembles adult, except for dark smudges on yellow skin of head. **Voice.** Mostly silent; has loud, harsh “aaoww” alarm call and melodious whistling contact call; persistent churring or grunting at roost gatherings.

**Habitat.** Primary or secondary forest in hilly, rocky terrain, usually close to running water; survives also in disturbed habitats, such as forest clearings, farmbrush and secondary growth, and in some cases close to human activity.

**Food and Feeding.** Food mainly forest floor-invertebrates, including insects, earthworms (Oligochaeta) and spiders (Araneae); beetles (Coleoptera), termites (Isoptera), ants (Hymenoptera) and grasshoppers (Orthoptera) the most frequently taken insects. Also eats vertebrates (frogs and lizards), and these constitute most of food biomass fed to nestlings. Forages singly, in pairs or in small groups on forest floor and on low vegetation not more than 1 m high; progression usually by bounding hops, and sustained flight rare. Uses large strong bill to turn over leaves. Frequently follows columns of army ants (Dorylinae) to capture prey flushed by the insects.

**Breeding.** Generally coincides with wet season, with egg-laying in Jun–Dec (peak numbers in Oct) and nestlings present Aug–Jan (highest numbers in Nov), with some regional variation; apparent laying in dry season in some parts of range, e.g. Dec and Mar in Liberia (Mt Nimba), possibly due to high elevation of site. Breeds in pairs (contrary to early suggestions of co-operative breeding), and defends nest vigorously, sometimes some vicious fights occurring. Nests singly or in small colonies of up to ten nests (only one or two nests at most sites). Cup-shaped mud nest built on rock face, cliff or cave roof; internal cup size varies markedly, average 10·8 × 17·2 × 12·9 cm.

Family PICATHARTIDAE (PICATHARTES)  
 SPECIES ACCOUNTS

Clutch usually 2 eggs; incubation by both parents, taking turns, median incubation period c. 20 days; chicks fed by both sexes, nestling period generally 25–26 days (extremes 23 and 29 days). Success apparently low, in Sierra Leone only 23% of eggs laid produced fledglings and only 0·44 young fledged per pair; known causes of failure are predation (including by humans), infanticide and cannibalism, competition from intruding conspecifics, and infertile eggs.

**Movements.** Resident; may range over several kilometres, but probably stays close to breeding sites/roosts all year.

**Status and Conservation.** VULNERABLE. Restricted-range species: present in Upper Guinea Forests EBA. CITES I. Populations fragmented, patchy and localized. Generally rare but widespread, and not uncommon in parts of its range. Mean range size 1·36 km<sup>2</sup> in Sierra Leone. Considered to have suffered, or is likely to suffer, a 20% population decline in ten years, or during course of three generations. Global population estimated at 2500–9999 individuals within geographical range of 391,000 km<sup>2</sup>. Decreasing population estimates due largely to declines in extent and quality of habitat. Protected by national legislation in most countries of its range. In Guinea, rare to common and widespread in S (from SW to SE) but unrecorded in N; current known localities are Grandes Chutes and Kounoukan (in Kindia province), Massif du Ziama, Mt Nimba and Diecke (in Nzerekore), and Mont Béro Forest Reserve (N of Nzerekore). Sierra Leone population estimated at c. 1500 birds, with bulk of these in Gola Forest in SE; rare but widespread throughout rest of country except in N, with known colonies in Western Area Peninsula Forest, Kambui Hills, Kangari Hills, Dodo Hills, Loma Mts and Nimini Hills. In Liberia rare to not uncommon, numbers increasing from coast to interior (most records from N highlands), and population estimated at 1000–2000 individuals; known breeding colonies in NW & W in Wologizi Mts and Wonegizi Mts, and Lofa-Mano (Lofa/Grand Cape Mount), and in N & E at Mt Nimba, Zwedru and Sapo. In Ivory Coast very local but not uncommon, with “best-guess” population estimate of 1500 individuals; occurs in W & S, at Mount Sangbé National Park, Nimba Nature Reserve, Mont Péko National Park, Lamto Research Station, and Taï Forest National Park, also at Geioule, Mt Glo, Mon Momi and Sangouni. Now uncommon and much localized in Ghana, with historical records confined to S third of country at Fumso (Central Region), Adumoa, Mpraeso (Ashanti Region) and Kwahu-Tafo, Abeti, Bekwai, Kumasi and Akwapim Hills (Eastern Region); until recent rediscoveries, in 2003, the species had not been seen in Ghana since 1960s; the most recent records are from Goaso (Eastern Region) and Asumura (Brong-Ahafo Region).

**Bibliography.** Anon. (2006), Borrow & Demey (2001), Butchart & Stattersfield (2004), Collar & Stuart (1985), Fry *et al.* (2000), Gatter (1997), Glanville (1954), Hall & Moreau (1970), Marks *et al.* (2004), Siaka (1997), Sibley & Ahlquist (1990), Sibley *et al.* (1988), Stattersfield & Capper (2000), Thompson (1993, 1997, 1998, 2004a, 2004b), Thompson & Fotso (1995), Thompson *et al.* (2004).

2. Grey-necked Picathartes

*Picathartes oreas*

**French:** Picatharte du Cameroun **German:** Buntkopf-Felshüpfer **Spanish:** Picatartes Cuelligris  
**Other common names:** Grey-necked Rockfowl, Red-headed Picathartes/Rockfowl

**Taxonomy.** *Picathartes oreas* Reichenow, 1899, Victoria, Cameroon.

Taxonomic position of genus subject to ongoing debate. Now generally considered to represent a monotypic family, related to “thrush-babbler assemblage” of the Timaliidae; has been suggested that closest relatives are the rockjumpers (*Chaetops*) of South Africa. May form a superspecies with *P. gymnocephalus*. Monotypic.

**Distribution.** Equatorial forest belt in SE Nigeria, W & S Cameroon, Equatorial Guinea including Bioko I (Fernando Póo), Gabon and SW PR Congo.

**Descriptive notes.** 33–38 cm; 200–250 g. Large odd-looking passerine with fairly long broad tail, long curved bill, and strong legs. Has bare head, with skin of forecrown lilac-blue to powder-

blue (this colour extending to proximal part of upper mandible, to above nostril), that of hindcrown and nape red (carmine or crimson), and triangular area of black skin on side of head (lores, cheek and ear region), with black band across crown between blue forecrown and carmine hindcrown; upperparts and tail dark bluish-grey, primaries and their coverts black (forming very distinctive band separating slaty back from yellowish vent); neck and throat to upper breast washed grey, rest of underparts soft lemon-yellow to light yellowish-buff; iris dark brown; bill black; legs grey. Sexes alike. Juvenile resembles adult, but head

colours seem to be absent at fledging. **VOICE.** Mostly silent, but sometimes gives low, quiet drawn-out rasping or hissing "wheet" call, 1–2 seconds long, repeated several times every c. 4 seconds, has been likened to sound of "heavy furniture being pushed across a gritty wooden floor"; single or double "peep" when approaching nest with food; on arrival at nest, utters regularly repeated low "ga-a-a".

**Habitat.** Rainforest; almost always encountered in primary or secondary forest, but may have greater tolerance of degraded habitat than previously believed. In Cameroon, associated with caves, cliffs and overhanging rocks in rugged and inaccessible places. Mainly in lowlands, but in Cameroon at up to 1800 m on Mt Cameroon and 2100 m on Mt Kupé; 250–900 m on Bioko.

**Food and Feeding.** Food mainly forest-floor invertebrates, including grasshoppers (Orthoptera), beetles (Coleoptera), earwigs (Dermaptera), ants (Hymenoptera), crabs (Decapoda), earthworms (Oligochaeta), slugs and snails (Gastropoda); also small vertebrates, primarily frogs and lizards, but in Nigeria fish found in crops of individuals caught near a river. Some vegetable matter also consumed. In one study, wide variety of insects found in crops of individuals, also fruits and flower buds, but animal food constituted majority of items. Forages singly, in pairs or in small groups on forest floor and on low vegetation, locally perhaps also at higher levels; progression mostly in bounding hops. Uses large strong bill to turn over leaves. Occasionally hunts among bat guano in caves. A strong follower of army-ant (Dorylinae) columns in forest. Rather inactive during midday hours; in Gabon, roosts in nest around midday and resumes foraging in afternoon.

**Breeding.** Associated with wet season, nesting twice yearly where rainfall distribution bimodal; nesting activity recorded Mar–Nov (peak between Aug–Nov) in Cameroon, and season given as Aug–Nov in Nigeria and Nov–Apr in Gabon. Apparently monogamous. Breeds singly or, where nest-sites limited, colonially, majority of colonies containing 2–5 nests. Nest built by both partners equally, a cup-shaped hard stone-like structure constructed from mud intermixed with rootlets and vegetable fibres, typical measurements 40 cm long, 29 cm wide and 14 cm thick (but considerable variation), usually built on rocks, cliff or cave roof. Clutch 1–3 eggs, usually 2 (mean 2.3); incubation period 21–24 days; nestling period c. 24 days. Many nests seem to be destroyed for reasons unknown, but current evidence points to cannibalism and predation as main causes of nest losses; predation by snakes thought to be rare, but chimpanzees (*Pan troglodytes*) known to destroy nests with eggs, and human hunters sometimes kill the adult birds.

**Movements.** Resident; probably stays close to breeding sites/roosts all year.

**Status and Conservation.** VULNERABLE. Restricted-range species: present in Cameroon and Gabon Lowlands EBA and Cameroon Mountains EBA. CITES I. Although overall range is relatively large (314,000 km<sup>2</sup>), population is highly fragmented, and considered to number fewer than 10,000 mature individuals; may be in overall decline, but new colonies are being found and numbers may yet prove to exceed the threshold for its current threatened status. Hunting and trapping are prohibited in Cameroon, but the species is apparently unprotected in all other range states. In Nigeria, known from total of c. 136 sites in SE, almost all in forests of Cross River State; locally common in undisturbed forest close to Cameroon border. In Cameroon, widespread in S & SW, mainly in coastal lowland rainforest; colony with 47 nests in Dja Biosphere Reserve may be the largest one known. On Bioko, limited to almost inaccessible terrain in SW (Gran Caldera de Luba and a 7-km stretch of R Olé at 250–900 m), where ten sightings reported in late 1980s; apparently some old records from mainland NW Equatorial Guinea. Most records from Gabon are from C & NE of the country, but in 2000 this species was discovered in SW (on Mt Doudo), representing a considerable range extension to the S. In Dec 1994, recorded for the first time in PRCongo, where one observed in relatively undisturbed forest in SW, c. 300 km from Gabon border (details of record not published until 2006); earlier reports that this species' range extends E to NE PRCongo apparently unfounded.

Class AVES  
Order PASSERIFORMES  
Suborder OSCINES  
**Family TIMALIIDAE (BABBLERS)**

- Tiny to rather large passerines, highly variable, most with short and rounded wings, usually relatively long tail often graduated, generally rather robust but not very deep bill, sturdy legs; plumage widely variable, many species rather plain and some dull brown, others strikingly patterned in contrasting and/or bright colours.
- 7–35 cm.

- Asia and Africa; one species in western North America.
- Forest, forest edge, scrub and grassland, from desert fringes to deep rainforest.
- 84 genera, 309 species, 872 taxa.
- 28 species threatened; none extinct since 1600.

### Systematics

For many years, the babblers were regarded as forming a subfamily within a greatly enlarged family Muscicapidae, but the distinctiveness of many species rendered this arrangement somewhat unsatisfactory, and resistance to the idea increased in the last quarter of the twentieth century. Indeed, opinions among taxonomists have not always been uniform even on the point of the babblers' proximity to the great thrush–chat–flycatcher–warbler assemblage, and the possibility that there could, in fact, be a closer affinity to the crows (Corvidae) and their allies was entertained into the 1960s.

Typical features of timaliids are plumage similarity of the sexes, largely adult-like juveniles lacking the general spotting characteristic of thrushes and chats (Turdidae), and short, rounded wings, a tendency towards a longer, rounded tail, generally a stout bill and legs, often soft, slightly lax body plumage, sometimes notably fluffier on the rump, and often a pale or reddish eye. Additional characteristics, relating to behaviour, are that the babblers usually practise direct head-scratching, often roost socially in a tight huddle along a branch, indulge in allopreening, and employ the foot in feeding, the last being a character which, indeed, allies them with the crows, the shrikes (Laniidae), the tits (Paridae) and the drongos (Dicruridae). Nevertheless, these are not the most robust or decisive of characteristics by which to identify a species as belonging within or outside the family, and it is a long-standing source of amusement among taxonomists and systematists that the family Timaliidae represents a “dust-bin” into which have been dropped all those taxa the affinities of which have been uncertain to these scientists or their predecessors; in 1896, Alfred Newton called the family both “a refuge for the destitute” and a “festering mass”. In recent years, however, biomolecular studies, particularly those led by A. Cibois, have been demonstrating the degrees of truth behind the joke. Unfortunately, as those studies are still in progress, we are not yet at the stage where it is appropriate to offer a major revision of the family as currently constituted, one that would reflect what is known so far. In the present arrangement, therefore, a number of species are included that are certainly not babblers, but which need to be retained in the Timaliidae for the moment while, among other things, scientists endeavour to clarify their true taxonomic positions. It is a frustrating circumstance, made all the more so by the knowledge that some groups of birds which are not presently included in the Timaliidae actually *are* babblers.

Among the latter, most awkwardly, the genera *Sylvia*, which is the type genus of the warbler family Sylviidae, and *Parisoma*, for which the English name “tit-babbler” was often used until it was considered instead a warbler, appear indeed to be timaliids, as do the parrotbills (Paradoxornithidae), the white-eyes (Zosteropidae) and at least one member of the sylviid subfamily Megalurinae, namely the Rufous-rumped Grassbird (*Graminicola bengalensis*). The biomolecular studies indicate that, intriguingly, the anomalous Bearded Parrotbill (*Panurus biarmicus*), which, with its pale eye, colourful wing pattern, graduated tail and social habit, looks and behaves so much like a babbler, has nothing to do with the parrotbills, but suspicions persist that it may eventually prove to be a babbler, having diverged as a result of a relatively rapid breeding rate. The discovery about the affinities of *Sylvia* is particularly unfortunate, because the family name Sylviidae precedes the family name Timaliidae by seven years,

*The babblers, one of the most diverse families of birds, are generally characterized by dull plumage and sexual monomorphism.*

*The Rufous-tailed Babbler is no exception to this rule. Placed in the monospecific genus Moupinia, it occurs in grass, thickets and scrub from north-west Yunnan to north Sichuan, China. It has a strongly curved culmen and a rufescent tone to the wings and tail, two features that are widespread in the family.*

[*Moupinia poecilotis*, Jizushan, Yunnan, China. Photo: John & Jemi Holmes]

One of the most significant discoveries arising from the recent spate of phylogenetic analyses is that the *Wren-tit* is a babbler, and therefore the sole New World member of *Timaliidae*. Previously thought to be an aberrant parid tit, it is genetically allied to *Sylvia* warblers (now also found to be babblers). This relationship is not entirely surprising given the shared characteristics between *Chamaea* and many *Sylvia*, including pale irides, general structure and habitat. The *Wren-tit* occurs in brush, scrub and dry forest in the states of Oregon and California, USA.

[*Chamaea fasciata henshawi*,

VIREO]

so that, technically, the name "Sylviidae" now stands for all species related to *Sylvia*; consequently, the babblers as we have known them for the best part of 200 years would have to transfer to an entirely newly constituted "Sylviidae". The situation is currently under consideration by the authorities, but the preferred option appears to be to incorporate the genus *Sylvia* into the existing *Timaliidae*, to keep the latter name and to suppress the name "Sylviidae", since this last family is, in any case, likewise starting to come apart under the remorseless unpickings of modern DNA work.

Species that are not babblers, and which are not included in the family as treated here, are the group known as the "Australasian babblers", sometimes called the "pseudo-babblers", and all except one of the "Malagasy babblers". As the biomolecular work by C. G. Sibley and J. E. Ahlquist indicated, the Australasian babblers are corvidan in affinities, and they occupy a family of their own, Pomatostomidae. In the case of the Malagasy group, the genera *Neomixis*, *Hartertula*, *Thamnornis*, *Oxylabes* and *Crossleyia* are now understood to be of "sylvine" (in the old sense) ancestry, with the first two assigned to the Cisticolidae and the second three to the Sylviidae. The remaining Malagasy genus, *Mystacornis*, although currently included in the *Timaliidae*, seems not to be a true babbler, although its affinities are not known. Ironically, M. P. S. Irwin, in his review of these birds, reserved his greatest doubts for *Mystacornis* as a babbler, but he was right in recognizing its clear difference from the other genera, and its appearance certainly makes it improbable that it is a timaliid species. Another "non-babbler" is the Sundaic endemic the Rail-babbler (*Eupetes macrocerus*). Previously placed in *Timaliidae*, this forest-dwelling species was reassigned to the Australasian babblers and, more recently, included with the *Ptilorrhoa* jewel-babblers and the related genera *Androphobus* and *Psophodes*, in fact becoming the type species for the family, Eupetidae, that embraces these genera. Now, new research indicates that *Eupetes* is not related to *Ptilorrhoa* at all but, rather, and surprisingly, to the South African genus *Chaetops*. The story twists further, because *Chaetops* is included in the present treatment of *Timaliidae*, even though it is not a true babbler.

Also apparently outside the family, despite their current inclusion within it, are the *Pteruthius* shrike-babblers and the species commonly named in the literature as the "White-bellied Yuhina", the White-bellied Erpornis (*Erpornis zantholeuca*). Independent work by Cibois and by S. Reddy indicates that these belong in the Corvoidea. Indeed, they are close to the vireos

(Vireonidae) of the New World, and it is now recommended that they be treated within that family. Several birdwatchers and ornithologists can congratulate themselves on having described the shrike-babblers as being vireo-like, biogeographically improbable as the connection may have seemed.

Other species close to the White-bellied Erpornis in the present arrangement either are not babblers, or not proven to be such, or have only recently been shown to be babblers. The position of the Chinese Bush-dweller (*Rhopophilus pekinensis*) has long been uncertain. This exhibits certain warbler-like traits and no very strong affinities to babblers, but J. D. La Touche, in the 1930s, observed that "on the whole, it is more of a Babbler than a Warbler" and "like the Babblers it is a good cage-bird, becoming very tame and docile"; very recently, DNA analyses appear to corroborate his view, the species showing links to both *Sylvia* and *Paradoxornis* and probably needing to be placed near the top of the sequence, perhaps somewhere between *Chrysomma*

The genus *Fulvetta* has been resurrected to address the polyphyly of *Alcippe*. It now contains eight species of evergreen forests in continental South-east Asia, each of them with a simple song, short rectal bristles and a long hind claw. This last feature is an adaptation, as these tit-like species often hang upside-down when foraging. All members of the genus, including the *White-browed Fulvetta*, have contrasting panels or flashes on the folded remiges.

Holmes]

and *Chamaea*. Similarly, the Bush Blackcap (*Lioptilus nigricapillus*), so odd that it has even been suggested that it could be a bulbul (Pycnonotidae), turns out to be close to *Sylvia* and might therefore be placed at the very head of the sequence, with *Pseudoalcippe*. The Juniper Babbler (*Parophasma galinieri*), usually known as the "Abyssinian Babbler" or "Abyssinian Catbird", is of as yet uncertain affinities. Another odd African isolate, the Principe Flycatcher-babbler (*Horizorhinus dohrni*), seems unlikely to be a timaliid, if only because the family demonstrates a congenital inability to cross big stretches of water, and it could just as easily be given the name of "bulbul-chat" or "thrush-warbler" as the one by which it passes here. Even so, it

was placed with the babblers because of the narrowing of the middle of the bill, as in the genus *Illadopsis*, and its voice resembles those of *Kupeornis* and *Ptyrticus*, the latter now known to be close to *Illadopsis*, so that the Principe Flycatcher-babbler may yet prove to be a valid member of the Timaliidae. Equally uncertain is Asia's Fire-tailed Myzornis (*Myzornis pyrrhura*), which has certain patterns in the wing which are reminiscent of some of the more colourful babblers and a bill and tongue similar to those of the *Malacias* sibilas, but it is different in structure, and may well have its roots elsewhere. So, too, may the *Malia* (*Malia grata*), a huge, strangely patternless bird by babbler standards, and one thought by C. M. N. White to be possibly a bulbul. *Malia* is part of an anomalous group of monotypic Sulawesi genera that are in great need of molecular analysis in order to determine their placement; the most obvious other candidates for such research are *Geomalina* and *Cataponera*, both of which have been treated as babblers in the recent past.

Meanwhile, molecular studies have shed enough light on the Grey-chested Kakamega (*Kakamega poliothorax*), the Spot-throat (*Modulatrix stictigula*) and the Dapple-throat (*Arcanator orostruthus*) to indicate that these belong, not with the babblers, but near the sugarbirds (Promeropidae) of southern Africa. In another delightful surprise, one that nobody would have been likely to credit without genetic evidence, the rockjumpers (*Chaetops*) of South Africa, long proposed as babblers because of the lax, fluffy plumage on their flanks, belly, lower back and, particularly, rump, turn out to be related to the two picathartes (Picathartidae) of West Africa, but are sufficiently distinct in structure, behaviour and breeding biology to be worthy of their own separate family, Chaetopidae. The Rockrunner (*Achaetops pycnopygius*), which shares the rather lax lower-body plumage of *Chaetops*, has endured a long, unhappy association with that genus, and even been treated as part of it, but in reality it is a somewhat different bird, moving in a mouse-like run, rather than a bold hop or jump; whether it has timaliid roots remains to be seen. The final species, the Madagascar Groundhunter (*Mystacornis crossleyi*), has already been mentioned; the only reason why it was ever mooted as a babbler appears to be its terrestrial habits. Incidentally, it has sometimes been thought that the Philippine creepers (Rhabdornithidae) might be babblers, and

Eight distinctive crested species of continental South-east Asia and Taiwan are placed in the genus *Yuhina*. They all have very slightly decurved and relatively pointed bills, with well-developed rictal bristles. The tail is short and square; the plumage is muted in greys, browns and whites; and the entire aspect is somewhat like a titmouse (*Baeolophus*). The **Whiskered Yuhina**, like its near relatives, is an active, group-living, flock-following species of humid evergreen forest edges.

[*Yuhina flavicollis rouxi*, Doi Lang, Chiang Mai, Thailand.

Photo: Kanit Khanikul]

The **Black-crowned Babbler** has traditionally been placed in the genus *Stachyris*, but it now joins four other Philippine species in *Sterrhoptilus*. These forest-dwelling forms have slender, pointed bills with moderate-length rictal bristles, streaked upperparts, and stiffened glossy crown feathers. The genus might need further subdivision as two members, the "pygmy babblers", are distinctive in their tiny size, their plumage pattern and the proportionately shorter bill.

[*Sterrhoptilus nigrocapitatus affinis*, Mt Maquilang, Luzon, Philippines.  
Photo: Doug Wechsler/  
VIREO]

Another group of Philippine species usually subsumed into *Stachyris* are now placed in *Zosterornis*. These five species, illustrated by the **Luzon Striped Babbler**, have relatively slender and pointed bills, with shorter rectal bristles than those of *Sterrhoptilus*. All but one has bold ventral streaking. The resurrection of endemic genera reinforces the impression that Philippine babblers are an ancient and highly divergent radiation.

[*Zosterornis striatus*,

it is interesting that, according to a recent observation, these two species head-scratch by the direct method, moving the foot under the wing, a behavioural trait unusual in passerines other than the babblers. The Philippine creepers, however, are such distinctive birds that it seems appropriate that they be accorded treatment as a separate family, at least until further DNA studies can illuminate their affinities. It has recently been proposed, on the basis of molecular evidence, that they belong, in fact, in the starling family (Sturnidae).

In a pioneering review which dominated the systematic treatment of the babblers for forty years, J. Delacour, who for the then enormous genus *Garrulax* depended largely on the insights

and ideas of his fellow countryman J. Berlioz, published 20 years earlier, arranged the Timaliidae into six tribes with 47 genera and 252 species. These were the "jungle babblers", tribe Pellorneini, with five genera (*Pellorneum*, *Leonardina*, *Malacocincla*, *Ptyrticus* and *Malacopteron*); the scimitar-babblers and wren-babblers, Pomatorhinini, with eleven genera (*Pomatostomus*, *Pomatorhinus*, *Xiphirhynchus*, *Jabouillea*, *Rimator*, *Ptilocichla*, *Kenopia*, *Napothera*, *Pnoepyga*, *Spelaornis* and *Sphenocichla*); the tit-babblers, Timaliini, with six genera (*Neomixis*, *Stachyris*, *Dumetia*, *Rhopocichla*, *Macronus* and *Timalia*); the wren-tit and parrotbills, Chamaeini, with five genera (*Chrysomma*, *Chamaea*, *Panurus*, *Conostoma* and *Paradoxornis*); the "song-babblers", Turdoidini, containing 18 genera (*Turdoides*, *Babax*, *Garrulax*, *Liocichla*, *Leiothrix*, *Myzornis*, *Cutia*, *Pteruthius*, *Gampsorhynchus*, *Actinodura*, *Haplopteron*, *Minla*, *Yuhina*, *Alcippe*, *Lioptilus*, *Phyllanthus*, *Crocias* and *Heterophasia*); and, finally, the tribe Picathartini, with the one genus *Picathartes*. Subsequent work by C. F. Mann, however, countered this. Mann studied the plantar surface of the foot, and his findings, apart from eliminating *Picathartes* as a babbler and providing poor evidence for *Kakamega*, *Mystacornis* and, intriguingly, *Pnoepyga*, being members, entirely failed to support any of Delacour's tribal arrangements.

An interesting but neglected revision of the babblers was furnished by H. Wolters in the 1980s. This redistributed the species into several families, not necessarily regarded as being most closely related to one another. Into the family Illadopsidae, the "mouse-babblers" or *Maustimalien*, went the African genera *Modulatrix*, *Kakamega*, *Ptyrticus*, *Illadopsis* and *Amaurocichla*, the last-named currently treated in the Sylviidae, and the Asian genera *Leonardina*, *Malacopteron*, *Trichastoma*, *Pellorneum* and *Malia* along with two more sylviids, namely *Oxylabes* and *Crossleyia*. Into the next family in sequence, Yuhinidae, the "tit-babblers" or *Meisentalien*, went the genera *Yuhina*, *Staphida* (= *Stachyris castaniceps sensu lato*) and *Erpornis*. Then, several families farther in sequence, came the true babblers, Timaliidae. Wolters was a notable "splitter" of genera, and he led a revival of the subgenus concept, so that this large family is full of unfamiliar names, although in many instances his perceptions have been vindicated by the DNA work that has superseded his general ar-

Seven similar species, often known as "nun-babblers", are placed in the genus *Alcippe*. The **Mountain Fulvetta** typifies this group in being rather uniform in appearance, with pale underparts, plain brown upperparts, and a grey head with dark lateral crown stripes. The culmen is curved and the tail slightly graduated, and roughly equal in length to the wing. The "nun-babblers" are rather common, obtrusive birds. They travel with mixed-species foraging flocks, vocalizing frequently, in the middle storey and at the edges of forests.

[*Alcippe peracensis*  
*peracensis*,  
Fraser's Hill, Malaysia.  
Photo: Teo Nam Siang]

The genus *Schoeniparus* contains three attractive species from continental South and South-east Asia. Previously subsumed into *Alcippe*, they are notable for their weaker bills, stronger feet, and longer hind claws. They also have beautifully striking head patterns, as demonstrated by this **Rufous-throated Fulvetta**. Unlike *Alcippe*, they tend to live in pairs or small groups low down in thick understorey, and rarely join mixed-species flocks.

rangement. In particular, his willingness to break down the monumental genus *Garrulax* into many constituent genera is a precedent readily followed in the current treatment in light of the molecular evidence of its polyphyly.

In 1990, the results of Sibley and Ahlquist's studies of DNA-DNA hybridization indicated that *Pomatostomus* and *Picathartes* did not belong with the babblers. In addition, these workers were the first to show the close affinities between the Wren-tit (*Chamaea fasciata*), originally thought, as its English name reflects, to be an aberrant parid tit, and the *Sylvia* warblers, something that subsequent molecular investigation has fully corroborated.

Studies by Cibois have taken the rearrangement of the babblers a great step farther, but reduced to rubble the tribal structure proposed by Delacour and found wanting by Mann. According to her findings, "*Yuhina zantholeuca*" is neither a yuhina nor even a babbler, *Kakamega* is not a babbler, and the *Pteruthius* shrike-babblers also belong elsewhere. The remainder of her sample, however, a total of 58 species in 28 genera, formed a monophyletic group that also includes *Sylvia* and *Zosterops*, the "true" *Yuhina* being very close to the latter, and involves several important repositionings and revivals of genera. *Pseudoalcippe* was found to be near *Sylvia*, and not with *Illadopsis* or *Alcippe*, both of which had been mooted previously as its close relations. *Alcippe* itself appeared to be polyphyletic, requiring the reinstatement of the genera *Fulvetta* and *Pseudominla*. The Philippine "tree-babblers", as *Stachyris* babblers are often called, proved to be closer to *Yuhina* than to other *Stachyris*, requiring the reinstatement of some older generic names, and even continental *Stachyris* did not form a monophyletic group. In Cibois's analyses, several species in Delacour's tribes Pomatorhinini and Timaliini turned out to form a clade, and the Pomatorhinini proved polyphyletic because the scimitar-babblers (*Pomatorhinus*) are not the sister-group of the wren-babblers (eight genera). Moreover, the wren-babblers in Delacour's arrangement are themselves polyphyletic, their similarities, which have perhaps been too readily presumed in the past, being due to convergence. Five wren-babblers, from the genera *Napothera*, *Jabouilleia* and *Kenopia*, formed part of another clade, which drew members of three of Delacour's tribes, the Pellornini, Pomatorhinini and Turdoidini. The genus *Garrulax* threw up different groupings from those proposed by Berlioz: the latter's assumption, backed by Sibley and Ahlquist, that *Liocichla* was embedded among the laughingthrushes was rejected, and Delacour's view of a close relationship between *Turdoides* and *Garrulax* did not find good support. Finally, the colourful, long-tailed babblers of the genera *Heterophasia*, *Leiothrix*, *Minla*, *Liocichla* and *Actinodura* form a clade separate from the Turdoidini in which Delacour had placed them.

Thus, we are left with more than 80 genera holding a combined total of more than 300 babbler species, but with no clear means of sorting them further phylogenetically. The greatest con-

The genus *Stachyris*, as currently constituted, contains twelve variable species with strong bills and often striking plumage. Some species, such as the **Sooty Babbler** (*S. herberti*), are morphologically anomalous, and perhaps require genera of their own. Others, such as the **White-bibbed Babbler**, equate more closely to the "standard" model: stout legs and unbarred plumage made up of rich browns and striking patches of grey, black or white. This species is a Javan endemic, and, like its congeners, a noisy understorey bird, often encountered as a dominant component of mixed-species foraging flocks.

[*Stachyris thoracica*.  
Photo: Konrad Wothé]

Scimitar-babblers in the genus *Pomatorhinus* are large, pair- or group-living species, with powerful repetitive vocalizations. Duets or choruses are the norm. They have relatively long, slender, decurved and laterally compressed bills, which are often used to dig in soil. Their long bodies are emphasized by prominent graduated tails.

Several lead a semi-terrestrial life, and perhaps as a result their legs and feet are very strong, and the claws long, especially the hind claw. The **Rusty-cheeked Scimitar-babbler** is essentially terrestrial, foraging on the ground amongst leaf litter, and occasionally hopping thrush-like up low boughs. In the breeding season it is generally found in pairs or family groups, but in most of its range these units coalesce to form roving bands of up to 12 individuals during the non-breeding season.

[*Pomatorhinus erythrogenys*.

Photo: Dennis Avon/Ardea]

greater than 50,000 km<sup>2</sup>, over 30% of babbler species qualify, whereas less than 25% of the more vagile and widespread Turdidae, the thrushes and chats, do so. One Endemic Bird Area, the Central Himalayas EBA, is defined entirely by the ranges of three babblers, namely the Nepal Wren-babbler (*Pnoepyga immaculata*), the Spiny Babbler (*Turdoides nipalensis*) and the Hoary-throated Barwing (*Actinodura nipalensis*), although the last is found also in the Eastern Himalayas EBA, where the greatest concentration of restricted-range babblers, 13 species in total, occurs. Here, in the mid-elevation forests of the Himalayas, the babblers may constitute as much as 20% of all passerine species, the figure falling to 6–15% elsewhere in the forests and scrub of the Oriental Region, and far lower still in equivalent habitat in Africa. One can picture how the dispersal might possibly have taken place, perhaps keeping to the warm and seasonally stable regions, moving east along mountains and south and east through lowland forest to the deep-water barriers across the Indonesian archipelago, and westwards chiefly by means of the dry-country *Turdoides*, the only genus shared by Asia and Africa, in the savannas of which it found a new lease of life. Only a very few species, such as the ancestors of Elliot's Laughingthrush (*Trochalopteron elliotii*), moved north to settle exclusively in the Palearctic.

As already noted, DNA studies have made this a time of considerable flux for babbler taxonomy, which has, in any case, been under scrutiny recently in terms of the number of species that the family holds. Even the number of genera is very uncertain. Just as relatively sedentary birds tend to develop higher numbers of localized species, so, too, may distinctions evolve between groups of species that may be reflected by increased generic allocations. The thrushes and chats have 336 species distributed among 60 genera, a rate of 5.6 species per genus, whereas the babblers as presently constituted have 309 species distributed among 84 genera, a rate of 3.7 species per genus, which is a very high level of differentiation. The definitions of these genera, which are often obscure, merit consideration here; their vocal characters are outlined later (see Voice).

The African *Pseudoalcippe*, with two species, has similarities to *Illadopsis* but exhibits major behavioural and vocal differences. The former species are solitary, foraging in the manner of *Sylvia* warblers in the middle storey, rather than in undergrowth, and have a beautiful mellow song. The proximity of the genus to *Sylvia* has now been corroborated by DNA analysis. Asian *Chrysomma* is characterized by the possession of a very short

The eight members of the genus *Spelaeornis* are tiny birds characterized by rounded tails with only ten feathers, soft plumage, short slender bills, rather long delicate toes, and a loud mechanical song. They are generally reclusive in dense undergrowth and difficult to see well without voice playback. The *Spelaeornis* radiation is centred on the eastern Himalayas and Myanmar, where isolated populations have diverged. The **Bar-winged Wren-babbler** occurs fairly widely in this region.

[*Spelaeornis troglodytoides sherriffi*, Eaglenest Wildlife Sanctuary, Arunachal Pradesh, India. Photo: Ramana Athreya]

centration of both species and genera is to be found in the eastern Himalayas and the ranges of adjacent western China, where a huge variety of habitats at different elevations and temperatures, and with different rainfall and seasonal regimes, was established as the mountains themselves arose, creating high levels of seasonal food resources among both invertebrates and plants. In India, for example, the bird list for the Buxa Tiger Reserve, in West Bengal, contains no fewer than 57 species of babbler, and this is by no means the highest number to be found at any one site. This region appears, therefore, to have been the cradle and long-term home of the timaliid radiation, in which the trophic adaptation to insectivory and frugivory on substrates less subject to seasonal extremes in food availability led to high levels of sedentariness, and this, in turn, led to high levels of local endemism.

Using the BirdLife International definition of endemism and "restricted range", which requires a species to occupy an area no

The *Pnoepyga* wren-babblers are tiny, semi-terrestrial birds with slender bills and diminutive front claws. Their tails consist of six extremely short rectrices, usually concealed by long rump feathers. Three of the four species come in two colour morphs. The individual pictured here is of the pale, or "white-scaled", morph of the **Pygmy Wren-babbler**, the most widespread member of the genus. It occurs from the Himalayas of Nepal and northern India, through South-east Asia to the Indonesian islands of Java and Timor. Some races, or groups of races, perhaps deserve treatment as species-level taxa.

[*Pnoepyga pusilla pusilla*, Doi Inthanon National Park, Thailand. Photo: Kanit Khanikul]

deep bill, a long graduated tail with the outer feathers about half the length of the central ones, and a clear, simple voice. The monospecific genus *Moupinia* differs from it in the reduced depth of the bill, generally smaller size and seemingly less rounded skull, which is perhaps a correlate of bill size in *Chrysomma*. *Chamaea*, the remarkable North American singleton in the family, and indisputably timaliid on both genetic and behavioural evidence, is at least superficially very close to *Moupinia* and a full analysis of the distinctions between the two is needed; the song of *Chamaea* is certainly less musical than that of *Moupinia*. All these species appear to group genetically close to *Sylvia*, and it may be that *Rhopophilus*, although treated with some suspicion in respect of its timaliid affinities and commonly regarded as a cisticolid, belongs in this general grouping, as perhaps do the parrotbills, towards which *Chrysomma* tends.

The monospecific fulvetta genus *Lioparus* has longer rictal bristles, a shorter, broader bill and a shorter hind claw than does *Fulvetta*, although its song is not greatly dissimilar to those of the latter. In plumage it is highly distinctive, with a head pattern recalling that of *Mesia* and bold wing and tail patterns suggestive of *Minla* and *Pseudominla*. *Fulvetta* itself, currently comprising eight simple-song species, has short rictal bristles and a long hind claw equal in length to the hind toe, presumably for hanging upside-down; unlike *Alcippe*, all eight species show to varying degrees a patterned wing, with bright panels or flashes on the folded outer primaries. The eight species of *Yuhina* have the bill very slightly to slightly decurved and relatively pointed, with well-developed rictal bristles, the head fully crested and the tail rather short and square; plumage colours are soft greys, browns and white, and each species displays streaking somewhere, on the flanks, the crest, the ear-coverts or the throat. *Staphida*, with three species, has a short thick bill, short rictal bristles, a short crest, a relatively long graduated tail, and the simplest imaginable song; the plumage colour and pattern are similar to those of *Yuhina*, but the whitish underparts suggest greater countershading.

In shape and bill morphology the bizarre monospecific *Dasyrotapha* resembles *Stachyris*, with which it was for long merged, but it probably belongs with the radiations of babblers in the Philippines, where six of the seven genera and 22 of the 23 species are endemic. Its bristly yellow forehead and elongate orange lateral crown plumes, along with its distinctive bare white ear-covert shafts, generally unusual plumage pattern and *Mesia*-like song, mark it out. *Sterrhoptilus* typically has a sharp slender

bill, moderate-length rictal bristles, relatively pointed wings, stiff, hair-like glossy crown feathers and streaked upperparts; the Golden-crowned Babbler (*Sterrhoptilus dennistouni*) exhibits the bristly yellow forehead and streaked upperparts of *Dasyrotapha*. The genus presently contains five species, although the two "pygmy babblers", distinct from the other three in their tiny size, proportionately shorter bill and general plumage pattern, merit taxonomic re-examination. The five *Zosterornis* babblers are slender and sharp-billed, with the plumage plain olive above and pale yellow below, four species having bold ventral streaking; the rictal bristles are shorter than those of *Sterrhoptilus*.

The rather plain *Alcippe*, with seven species sometimes referred to as "nun-babblers", has the culmen curved and the tail and wing of equal length, the former only slightly graduated. The upperparts are plain brown, usually greyer on the head and with a long dark lateral crownstripe, and the underparts are buffy to whitish. The three *Schoeniparus* fulvettas are like *Alcippe* and have very similar voices, but they are more strongly patterned, with stronger legs and feet and, as *Fulvetta*, a longer hind claw, and they display a tendency to keep close to the ground. The monospecific *Rhopocichla*, from south-west India and Sri Lanka, has the nostrils more rounded than those of *Alcippe*, well-developed rictal bristles and the tail shorter than the wing; the black crown and face are very distinctive, and it is not clear what its closest relatives are. Similarly, the monospecific Indian *Dumetia* resembles *Stachyris* in general appearance, but it has a longer tail, its eggs are spotted and it is a poor vocalist.

The genus *Stachyris*, with twelve species, is characterized by the possession of a strong bill, that of the larger species having the culmen gently curved. For those members for which the relevant information is available, the eggs are white, the Chestnut-winged Babbler (*Stachyris erythroptera*) being a partial exception in that the eggs of its Myanmar population are speckled reddish. The plumage colours and the size of *Stachyris* babblers are variable, from all brownish-black and large, as typified by the Sooty Babbler (*Stachyris herberti*), which is also aberrant in having a pale bill and may merit retention in its own genus, *Nigravis*, to brown, grey, white and small, as in the White-breasted Babbler (*Stachyris grammiceps*); species in between these extremes are a rich dark brown with various bold black and white markings. Even with the removal of four smaller babblers from *Stachyris* to *Stachyridopsis*, there is still some question over whether this amount of visible diversity is appropriately contained in a single genus.

The genus *Macronus* contains six species, two of which are rather distinctive in bearing elongated vaneless shafts from three separate tracts, one on the back and one on each flank. These bare shafts usually drape inconspicuously over the tail and wings, as demonstrated by this **Fluffy-backed Tit-babbler**, but they can be raised in a spectacular puff-backed display. The remaining four *Macronus* species lack these plumes and are rather different morphologically, with narrower bills and streaky underparts. They probably belong in a separate genus.

Seven Afrotropical species were once included in the Asian genera *Malacocincla* and *Trichastoma*, but this treatment overlooked their unique vocal and morphological features, including smaller bills, rictal bristles, legs and feet. All seven are characteristic birds of the understorey of African forests, where they are much more easily heard than seen. This is just as well because they are easier to identify by ear than by eye! They are now placed in the genus *Illadopsis*. The **Pale-breasted Illadopsis**, a typical example, is generally dull brown with a grey head and whitish underparts.

[*Illadopsis rufipennis* *rufipennis*, above Etome, Mt Cameroon, Cameroon. Photo: Doug Wechsler/VIREO]

Far more uniform are the 14 species of scimitar-babbler in *Pomatorhinus*, a genus typified by the relatively long, slender, decurved and laterally compressed bill, the rather long body emphasized by the graduated tail being longer than the wing, the long strong claws, notably the hind claw, and the duetting habit. In body shape, claw size, head pattern, with pale supercilium and throat, and song, the monospecific genus *Xiphirhynchus* is clearly very closely related to *Pomatorhinus*, but it possesses a much longer, much slenderer and still more curved bill, altogether of a different type.

*Sphenocichla*, with two rather similar-looking species, is distinguished by the sharp, pointed but relatively long conical bill. It has no rictal bristles, the tail feathers are greatly rounded, the legs are strong with a fairly long hind claw, and the songs are well structured. The much smaller *Spelaornis* wren-babblers, eight species in number, have a rounded tail with only ten feathers, soft full plumage, the females being slightly warmer below, a rather narrow short bill with a downward-sloping culmen, rather long delicate toes, and a loud mechanical song. The monospecific *Elachura* is very similar to *Spelaornis* and was once merged with it, but it has a decidedly longer bill and a very high-pitched song, seeming to link it with *Pnoepyga*. All four species in the latter genus have an extremely short tail consisting of only six soft feathers concealed by long ample rump feathers, along with a long thin bill, as long as that of *Elachura*, and relatively tiny front claws. Three of the four occur in two colour morphs.

The four *Stachyridopsis* species are distinguished from *Stachyris* by having the culmen entirely straight, making a shallow-based dagger shape, and their song is different in structure, with affinities to *Macronus*. The two species of *Micromacronus* are extremely small, with a thin and slightly decurved bill, tiny and slender legs and feet and, most distinctively, elongate and thickened white bare shafts extending backwards around the tail and wings from three points on the body, one on the back and one on each flank. Two of the six species of *Macronus*, the Fluffy-backed Tit-babbler (*Macronus ptilosus*) and Stripe-headed Tit-babbler (*Macronus striaticeps*), show the same arrangement of white vaneless shafts, but these are chunky, stout-billed birds and hence rather divergent from the remaining four, which are smaller, are narrower-billed, and have various intensities of streaking on pale yellow underparts and brown upperparts with no bare shafts; in this case, a reconsideration of generic limits seems, therefore, appropriate. Monospecific *Timalia* has peculiar rigid crown-

feather shafts, a relatively short, deep-based bill and a strongly graduated tail longer than the wing, but it groups with *Macronus* genetically.

The spelling of the genus *Macronus* has been a matter of some confusion. In the original 1835 description, it appeared as "*Macromus*" on the plate but "*Macronous*" in the text. The first spelling was in general use up to 1964, at which point the second was adopted by H. G. Deignan in J. L. Peters's *Check-list of Birds of the World*, thence spreading into a great deal of ornithological literature. However, in accordance with the ICZN Principle of the First Reviser, G. R. Gray's 1855 citation of both spellings and adoption of "*Macronus*" means that this form necessarily becomes the correct spelling.

The African Thrush-babbler (*Ptyrticus turdinus*), in yet another monospecific genus, is characterized by its thrush-like ap-

Five Asiatic species are grouped together in the genus *Malacocincla* on account of their strong legs, large feet, and relatively short tails. **Abbott's Babbler** is especially dumpy in structure, the head and bill appearing too large for the rear body and tail. This species is widespread and often common in lowland forests from Nepal to Sumatra and Borneo. Like its congeners, it is highly vocal and more readily encountered (and identified) by voice.

[*Malacocincla abbotti obscurior*, Taman Negara National Park, Malaysia. Photo: Ong Kiem Sian]

The genus *Pellorneum* is an unconvincing assemblage of eight Asiatic babbler species. These are rather variable but generally characterized by short, weak rictal bristles, relatively long legs and claws, and a tail shorter than the wing. The **Black-capped Babbler** typifies most of these species in being semi-terrestrial, and preferring to walk, rather than hop, when foraging. It is perhaps the most beautiful member of the genus, its inky black cap, white throat and rich rufous chest perfectly captured in this admirable portrait.

[*Pellorneum capistratum nigrocapitatum*,  
Khao Pra-Bang Khram  
Wildlife Sanctuary,  
Krabi, Thailand.  
Photo: Kanit Khanikul]

pearance, mid-brown above and white below with vague mid-brown breast spotting, and its bill and legs are also sturdy and thrush-like, the legs and toes in fact being stronger than those of a Song Thrush (*Turdus philomelos*), even though the babbler is considerably smaller and lighter than that species. The seven species of *Illadopsis* have some vocal similarity with *Ptyrticus*, but all are much smaller, with proportionately smaller bill and legs, and have rather uniform, restrained coloration. Their one-time placement in one or other of the Asian genera *Malacocincla* and *Trichastoma* failed to take account of the much shorter bill of *Illadopsis*, the shorter and less obvious rictal bristles, the somewhat smaller legs and feet, the more proportionate wing:tail ratio and the somewhat different voice.

*Pellorneum*, consisting of eight species, has short, weak rictal bristles and, except for the Marsh Babbler (*Pellorneum*

The **Bagobo Babbler** is restricted to the Philippine island of Mindanao. It is often placed in the genus *Malacocincla* but differs in a range of features, suggesting that the monotypic genus *Leonardina* should be retained. In particular, it has a relatively long tail and tarsi, short toes, and a more slender bill, with round rather than oval nostrils. Its vocalizations are also entirely different, more closely resembling those of another endemic Philippine genus, *Robsonius*.

[*Leonardina woodi*,

VIREO]

*palustre*), a tail shorter than the wing, and fairly long strong legs and claws. The members of this genus commonly walk, but sometimes hop, and, again with the exception of the Marsh Babbler, have simple whistled songs. *Malacopteron*, with five species, possesses a rather long bill with an upcurved lower mandible and hook-tipped upper mandible, conspicuous rictal bristles, and small legs and feet, these last being related to its arboreal habits; in addition, it indulges in group songs and much song-duetting. The monospecific genus *Ophrydornis* has the bill, bristles and feet similar to those of *Malacopteron*, although the bill is somewhat shorter and broader-based; indeed, it is usually merged with *Malacopteron*, but it is proportionately shorter-tailed and "stubbier" in body shape, and has a distinctive head pattern. The five species of *Malacocincla* have the bill and rictal bristles as *Malacopteron*, but with strong legs, large feet, and the tail considerably shorter than the wing. *Trichastoma*, with three species, is very close to *Malacocincla*, from which it differs mainly in having a longer, better-proportioned tail.

The monospecific Philippine genus *Leonardina* has, like *Illadopsis*, been synonymized with *Malacocincla*, by E. Mayr and Delacour, and with *Trichastoma*, by Sibley and B. L. Monroe, but it differs from both in its longer tarsus, shorter toes, rounded rather than oval nostril, slenderer bill, and entirely different song. The song is like that of another Philippine endemic, *Robsonius*, the two species of which are commonly placed in *Napothera* but, apart from their insect-like voice, differ from that genus in lacking rictal bristles and in having part-feathered nares, broad white tips on the wing-coverts and outer primaries, copious elongate rump feathering, a fairly long and slightly hooked bill, and a walking habit.

Yet another monospecific genus, *Kenopia*, is a distinctive small babbler with a rather deep, slightly hooked bill, and stiff brush-like loreal feathering. It hints at *Robsonius* in its lack of rictal bristles and its rather fluffy dense rump feathering, while the long white markings on the breast side and back are suggestive also of *Ptilocichla*, although its feet are proportionately rather small, indicating its less exclusively terrestrial behaviour. *Ptilocichla*, with three species, has a rather long, hook-tipped bill, very short, weak rictal bristles if present at all, and powerful legs and feet, as well as a distinctive plumage pattern with elongate breast and flank feathers marked with long white streaks, and, as *Robsonius*, copious rump feathering. Indeed, in bill shape and head pattern the Palawan Ground-babbler (*Ptilocichla falcata*)

rather resembles *Robsonius*, while the Bornean Ground-babbler (*Ptilocichla leucogrammica*) has been reported as having the appearance, gait and call tonality of the quite unrelated Rail-babbler, although this second parallel, if not the first, must certainly be a case of convergence.

In most lists, the genus *Napothera* consists of nine species, as it incorporates the genera *Robsonius*, *Turdinus* and *Gypsophila*. The two *Robsonius* species, mentioned above, are normally treated as conspecific. Of the others, the four species in *Turdinus* form a clear group, all fairly chunky medium-sized babblers with rather long, strong legs, feet and claws, the rump feathers notably copious, long rictal bristles, rather dark plumage with scalloped, marbled and diffusely streaked patterning, and simple songs. The somewhat smaller monospecific *Gypsophila*, which most closely resembles the Large Wren-babbler (*Turdinus macrodactylus*), has much shorter rictal bristles, feathering over the basal part of the nares, notably short rounded wings, and distinctive vocalizations. The three *Napothera* species, differing slightly in size but all smaller than *Gypsophila*, are united by their simple piping songs, the fact that the tail is shorter than the wing, the possession of fluffy rump feathering, and a colour pattern of dark brown upperparts with blackish scales and pale streaks, a whitish throat and tan-coloured, slightly streaky breast and belly. The two smaller species have a medium-length bill, short rictal bristles, and small whitish spots on the tips of the upperwing-coverts and flight-feathers, while the Mountain Wren-babbler (*Napothera crassa*) possesses a proportionately rather shorter bill and long rictal bristles, and has no spots on the wings. If these features of the last-mentioned species were considered worthy of generic recognition, the name *Lanioturdinus* is available, but molecular evidence suggests that it is not divergent from its congeners, the Streaked (*Napothera brevicaudata*) and Eyebrowed Wren-babblers (*Napothera epilepidota*). *Rimator* belongs here, having echoes of *Ptilocichla* in its elongate underpart feathering with long pale streaks, and of *Napothera* in its simple piping whistle, short rictal bristles, dark brown and buffy-tan overall coloration and lax plumage, but it stands alone for its long decurved bill equal in length to or longer than the head, its short rictal bristles, its very short tail, and its very strong legs and feet and fairly long and sturdy claws, notably the hind claw. The genus *Jabouilleia* was established for the Indochinese Wren-babbler (*Rimator danjoui*) but there appear to be no significant differences between this and the three other *Rimator* species apart from its greater size and

apparent underpart streaking; Cibois's DNA analysis showed *Jabouilleia* to be close to *Napothera* as presently defined.

The two bamboo-specialist *Gampsorhynchus* babblers are distinguished by their deep, hook-tipped, rather shrike-like bill, long, strong rictal bristles, long graduated tail, and strikingly pale coloration, pale brown above with white head and underparts, as well as their highly social behaviour with its concomitant noisy grating cackling. Molecular studies place this unusual genus close to the very different-looking *Pseudominla*, a genus of four species in which the tail is shorter than the wing, the rictal bristles are short, the bill is narrow and the voice is relatively pleasant. *Pseudominla* has a streaked crown and white or yellow supercilium, and the wing of some species is boldly patterned. Because it

The genus *Ptilocichla* contains a trio of species with rather long, hook-tipped bills, short rictal bristles, and sturdy legs and feet, the latter being adaptations for a semi-terrestrial lifestyle. The plumage is relatively full and copious on the rump, and marked with long spear-like streaks on the breast and flanks. All members of the genus inhabit humid evergreen forests, with one form on Borneo, another on Palawan, and the third, the **Streaked Ground-babbler**, occurring more widely on islands of the Philippine archipelago.

[*Ptilocichla mindanensis*, Pasonanca Watershed, Zamboanga, Mindanao, Philippines.  
Photo: Robert Hutchinson/ Birdtour Asia]

As their scientific name suggests, the *Turdinus* babblers resemble short-tailed thrushes. They are a well-defined group of four reclusive, bulky, semi-terrestrial species inhabiting the lower strata of humid forests. Their legs, feet and claws are long and sturdy, their rictal bristles long, and their rather dark plumage is generally scalloped or marbled. Like its congeners, the **Large Wren-babbler** has a loud, uncomplicated, whistled song, to which it responds aggressively. Its bare ocular skin is reminiscent of certain Neotropical antbirds (*Thamnophilidae*).

[*Turdinus macrodactylus* macrodactylus, Khao Pra-Bang Kham Wildlife Sanctuary, Krabi, Thailand.  
Photo: Kanit Khanikul]

The genus *Napothera* contains three short-tailed, forest-dwelling species, each with copious rump plumage, dark brown upperparts with blackish scales and pale streaks, a whitish throat and tan-coloured breast and belly.

Their songs consist of simple piping whistles. Two of these species are widespread in South-east Asia, and another, the **Mountain Wren-babbler**, is restricted to Borneo. This island form is slightly larger, with a shorter bill and longer rictal bristles than its continental relatives. It also has no pale spots on the wing-coverts.

was formerly lumped, together with *Fulvetta* and *Schoeniparus*, in *Alcippe*, and as all four genera are known as fulvettas, it is worth summarizing some of their apparently diagnostic characters. Thus, *Fulvetta* has a small stubby bill, short rictal bristles, a long hind claw and a patterned wing; *Alcippe* has a short, stout bill, long rictal bristles, a shortish hind claw and an unpatterned wing; *Schoeniparus* is like *Alcippe* in its bill, rictal bristles and wing pattern, but with stronger legs; and *Pseudominla* possesses a relatively thin, long bill, fairly well-developed rictal bristles, a long hind claw and, with one exception, a patterned wing and, uniquely, crown. The one species in *Pseudominla* that fails fully to conform is the Yellow-throated Fulvetta (*Pseudominla cinerea*), whose wing has no "flash" or panel; this species is also

*Rimator* is a genus of peculiar, semi-terrestrial babblers. It once contained a single species, the **Long-billed Wren-babbler**, but this has increased to four species, with the elevation to species rank of two isolated forms from Sumatra and north Vietnam, and the inclusion of another monotypic genus (*Jabouilleia*). All these species have long, decurved bills, short tails, and strong legs, feet and claws. Their songs consist of long piping whistles, and this is often the best clue to their presence. They are generally furtive and inconspicuous, foraging close to the ground in evergreen forests.

remarkable for the way in which, in museum specimens, the yellow of the plumage fades so much that the upperparts become dull grey and the underparts whitish. Whether there is taxonomic information in these features remains to be decided. As E. Pasquet's recent phylogeny suggested that *Pseudominla* and *Schoeniparus* are not mutually monophyletic, whereas morphological evidence indicates that these two groups possess unique characters, further analysis will probably be necessary.

Containing a total of 29 species, *Turdoides* is the largest genus in the family. It is characterized by the possession of a strong, point-tipped bill both mandibles of which are slightly decurved, short rictal bristles, firm short forehead feathering, a long, well-graduated tail and, with the exception of the black-and-white Southern Pied Babbler (*Turdoides bicolor*), a relatively drab coloration of pale brown, pale grey and whitish, sometimes darker brown and grey, almost always with some streaking or scaled effect on the crown, back or breast. One of its members, the Spiny Babbler, is distinctive owing to the sharp pointed tips of the feathers of the upperparts and, especially, the underparts, and because of its unusually musical song. Wolters revived the genus *Acanthoptila* for this species, but more work is needed to justify the following of this lead. The same is true for his use of the genus *Argya* for the species *gularis*, *longirostris*, *malcolmi*, *subrufa*, *earlei*, *caudata*, *altirostris*, *squamiceps* (type of the genus), *fulva*, *rubiginosa* and *aylmeri*. *Argya* is supposed to apply to those species having a longer, more graduated tail, a longer, slenderer bill and a less rounded wing, but the aforementioned species do not all conform to this definition and it is not clear which criteria they may meet. On the other hand, the relatively small, slender African species of *Turdoides* often known as "chatterers", namely the Fulvous (*Turdoides fulva*), Bare-eyed (*Turdoides aylmeri*) and Rusty Babblers (*Turdoides rubiginosa*), have quieter and higher-pitched contact calls and more skulking behaviour than those of other members of the genus, but it remains unclear whether a full assessment of all the species would reveal constant discrepancies in morphology, voice and behaviour worthy of taxonomic recognition beyond the subgenus.

Two small African forest genera, *Phyllanthus*, with one species, and *Kupeornis*, with three, may possibly prove to derive from *Turdoides*, since both live in flocks and perform chattering choruses, and both have the same general appearance and shape, with short rictal bristles. Moreover, *Phyllanthus* is very like *Turdoides* in foraging habits and *Kupeornis* is judged to fly in a manner very like that of *Turdoides*. *Phyllanthus* is, however,

shorter-tailed and much stronger-legged, and has a distinctive rich dark chestnut or blackish-maroon plumage with a grey hood. One species of *Kupeornis*, the White-throated Mountain Babbler (*Kupeornis gilberti*), is notably similar to *Phyllanthus*, being only slightly smaller, with proportionately smaller bill and legs, and with a similar coloration, albeit with a white face and throat. The three *Kupeornis* are, however, united by the possession of very short rictal bristles, a short to medium-length yellowish bill, a pale iris, a capped appearance with erectile crown feathers, a rather short rounded tail, and a strongly curved hind claw, the last utilized during acrobatic foraging on branches.

*Cutia* is a delightful anomaly, a remarkable mix of colours and patterns quite unlike those of any other babbler, but, as in many of the family, with a large colourful wingpanel. In addition, it exhibits strong sexual dimorphism, has the bill decurved to a point like that of a miniature *Turdoides* and with a very slight notch at the tip of the upper mandible, and has very short rictal bristles and greatly developed uppertail-coverts. It was long thought to be related to *Pteruthius*, also brightly coloured, sexually dimorphic, strong-billed and canopy-dwelling, but molecular evidence does not support such an affiliation.

The genus *Garrulax* formerly encompassed an enormous variety of species, with some of the most striking and beautiful of colours. Indeed, the multiplicity of colorations, along with their relatively large size, rather strong, medium-length bill, powerful legs and feet, short wings, and long rounded or graduated tail, was a kind of taxonomic character that held them together. As noted earlier, Wolters took the step of breaking down Delacour's great genus into far smaller components, and P. C. Rasmussen and J. C. Anderton, in their *Birds of South Asia*, published in 2005, were the first popularizers of this revised approach. In the present treatment, the "old" *Garrulax* is divided into eleven genera, including *Babax*, which Delacour treated separately but which has been found genetically to sit among various other members of the old genus. Even so, it is by no means clear that the attributions to genus in the current treatment are correct or appropriate, or even that the number of genera is yet correct; there may be too many, but there may also be too few. Moreover, the sequence both of genera and of species within each genus is little short of guesswork. Considerable revision is undoubtedly still required.

*Dryonastes*, with eleven rather divergent species, cannot easily be diagnosed. Most of its members have the nostrils half-hidden by forward-lying bristles, and a bill that is shorter than

the head, although the Wynaad Laughingthrush (*Dryonastes delesserti*) breaks this second rule. They are also generally smaller in size than species of *Garrulax*, as currently constituted, which have the nostrils supposedly most exposed. All have a short-bristled loral area, black in all except the Rusty Laughingthrush (*Dryonastes poecilorhynchus*) of Taiwan, but this is a character that the genus shares with *Garrulax* except for the two necklaced laughingthrushes and Sri Lanka's Ashy-headed Laughingthrush (*Garrulax cinereifrons*), something which may be taxonomically indicative. All except one of the *Garrulax* species with a bristly loral region have this area black; the exception is the Rufous-fronted Laughingthrush (*Garrulax rufifrons*) of Java, in which the loral area is chestnut, as that of the Rusty Laughingthrush, possibly suggesting a cross-generic link between these two taxa. In terms of song, *Dryonastes* can be subdivided into three groups, these according also with their social structures (see Voice), but it is not yet clear whether this is of taxonomic value. The first three species in the sequence, the Grey-sided (*Dryonastes caerulatus*), Chestnut-winged (*Dryonastes berthemyi*) and Rusty Laughingthrushes, form a distinctive soft-plumaged group with particular attributes that might warrant generic separation. One final character that separates *Dryonastes* from *Garrulax* reasonably well is the presence of a paler panel on the primaries formed by more brightly coloured fringes than those on the rest of the wing, but this is a feature displayed better by the two necklaced laughingthrushes than it is by a couple of species here assigned to *Dryonastes*. Moreover, there is an interesting morphological parallel between the Rufous-necked Laughingthrush (*Dryonastes ruficollis*) and the Rufous-cheeked Laughingthrush (*Garrulax castanotis*) that suggests a link between the two, despite their difference in size. Both genera have moderately long rictal bristles.

*Garrulax*, now with 15 species, breaks into several groups. The first seven are the literal "laughing" songsters, and these share various characters, including large size, long and ample head feathering, and a tendency towards an abrupt, if sometimes subtle, change in colour between the breast and the lower underparts. The two necklaced laughingthrushes and two white-throated species, namely the White-throated (*Garrulax albogularis*) and Rufous-crowned Laughingthrushes (*Garrulax ruficeps*), share a breastband and a white-tipped tail, and the final four, the Masked (*Garrulax perspicillatus*), Rufous-fronted, Ashy-headed and Sunda Laughingthrushes (*Garrulax palliatus*), are all rather dull uniform brown, or brown and grey.

Gampsorhynchus babblers are distinguished by their deep, hook-tipped bill, long graduated tail, and strikingly pale coloration, including a distinctive white head. They are highly vocal and social, often occurring in mixed-species flocks, and spending much time in the middle storey of second growth and patches of bamboo. The genus probably contains two species-level taxa, with South-east Asian races here split off to form the **Collared Babbler**, named in reference to the partially concealed dark brown collar which separates the white head from the fawn body.

[*Gampsorhynchus torquatus torquatus*, Thailand.  
Photo: Roland Seitre]

*Turdoides*, the most species-rich babbler genus, is mainly associated with arid or open country. Its 29 members are a medley of muted colours, usually with distinct fine streaking or scaling; a few species are spectacularly pied. In all cases the bills are strong and sharp, with short rictal bristles at the base. The feathers of the forehead tend to be short and dense, while the tail is usually long and graduated.

The **Arrow-marked Babbler** typifies the group. It is widespread in Africa, occurring from Kenya to South Africa in savanna, thorn-forest, open woodland and the edges of cultivation. Sometimes, as pictured here, it occurs in reedbeds and the margins of wetlands. Like its congeners, it lives in noisy, co-operatively breeding groups.

convergens,  
Stone Hills Game  
Sanctuary,  
Zimbabwe.  
Photo: R. Peek]

*Melanocichla*, two species endemic in the Sundaic region, has a large, deep, rather short pale (red) bill with a steeply curving culmen, bare skin behind the eyes, all-dark plumage and a distinctive whooping voice. *Rhinocichla*, with a further two Sundaic species, also has a pale (yellow) bill and dark body plumage, but the bill is much smaller, the crown is distinctively coloured and there is a bold white wing flash; the rictal bristles are the most pronounced of those of all the laughingthrushes, whereas they are weak in *Melanocichla*.

The three species of *Babax* are superficially reminiscent of *Turdoides* with their streaky brown, buff and grey plumage and a rather long decurved bill, which also resembles that of the scimi-

tar-babblers in *Pomatorhinus*; the song is a simple series of whistles. The monospecific *Grammatoptila*, although also large, brown and streaky, is perhaps only superficially similar to *Babax*, with the feathers of the body elongate and patterned as in *Ptilocichla*, a crest recalling that of the White-crested Laughingthrush (*Garrulax leucolophus*) and a uniquely deep, short bill resembling that of a turaco (*Tauraco*). In the rather small *Stactocichla*, containing two species, the bill is relatively long, straight and slender, the breast uniquely speckled, the tail relatively short, being roughly the length of the wing, and the song magnificent. *Leucodioptron* quite closely resembles *Stactocichla* and likewise consists of two species, with the Chinese Hwamei (*Leucodioptron canorum*) completing the white "eyebrow" only hinted at in the Spot-breasted Laughingthrush (*Stactocichla merulina*), but it has a shorter and deeper bill, the spots turn to narrow streaks, and the song, while rich, is simpler. The five species in *Strophocincla* are also small and reddish-brown, like members of *Stactocichla* and *Leucodioptron*, but with a relatively small, slender bill. The two species from southern India, however, lack the finely streaked plumage of the other three, and have much longer rictal bristles; they probably require a new genus.

The two species comprising *Pterorhinus* are united by their rather nondescript pattern and colour and their distinctive vocalizations, but they differ somewhat in bill morphology. In overall plumage they are close to *Ianthocincla*, or at least to one of its members, the Snowy-cheeked Laughingthrush (*Ianthocincla sukatschewi*). All eight species in the latter genus, however, are characterized by the possession of pale, usually white tips on at least the tertials and secondaries, and bold white or, in one case, rusty tips on the rectrices; all have a longish straight or slightly decurved bill and rather strongly coloured wingpanels, most present a capped effect, even if only by having no markings on the head but markings on the back, and there is a tendency towards scaling on the underparts. *Trochalopteron*, with its 16 species, continues that tendency and also exhibits coloured wingpanels, but the bill is generally smaller, the culmen more evenly decurved, the plumage is darker and richer in browns, greys and olive tones and, apart from a vestigial appearance in the Brown-capped Laughingthrush (*Trochalopteron austeni*), the flight-feathers lack pale tips.

As with many of the genera still to be reviewed, *Liocichla* has had its scientific name appropriated for the English vernacular, suggesting the exhaustion of the options for combining the

A single African species, the **Capuchin Babbler**, occupies the genus *Phyllanthus*. It bears some behavioural and structural similarities to *Turdoides* babblers but it is thicker-set, with much stronger legs and a shorter tail. Its plumage is mostly blackish with a unique rich maroon tinge, except for the head, which bears a distinctive grey hood. Like *Turdoides* babblers, it forages in chattering groups, but unlike them it inhabits lower and middle strata of humid evergreen forests.

[*Phyllanthus atripennis*.  
Photo: M. Hyett/VIREO]

The **Himalayan Cutia** is hardly recognizable as a babbler. Not only does it forage by creeping along branches in forest canopies like an overgrown nuthatch (*Sitta*), but it is strikingly patterned and colourful, with pronounced sexual dichromatism. Its bill is decurved and pointed, the upper mandible bearing a slight notch at the tip. The rictal bristles are very short, and the uppertail-coverts are long, almost covering the short tail. The Malaysian race, pictured here, has richer chestnut upperparts and a buffier vent than Himalayan and South-east Asian forms, as well as slightly different vocalizations.

[*Cutia nipalensis cervinicrissa*,  
Fraser's Hill, Malaysia.  
Photo: Bernard Van Elegem]

The genus *Dryonastes* contains eleven attractive species of Asiatic forests. They tend to have short, black bristles in the loreal area, with some of those bristles jutting forwards to conceal much of the nostril. Several taxa are also notable for the pale panel in the outer wing formed by fringes to the primaries. In general, however, it is difficult to pinpoint diagnostic features of this genus, making further taxonomic evaluations necessary using genetic analyses.

The **Blue-crowned Laughingthrush** is a localized Chinese endemic previously merged with the Yellow-throated Laughingthrush (*D. galbanus*).

[*Dryonastes courtoisi*.

Dean]

word “babbler” with some other descriptor, and readily falling back on the simplest solution. *Liocichlas* appear to be close to the “garrulacine” babblers—indeed, the two “red-faced” species, larger and longer-billed than the others, were sometimes treated in the old *Garrulax* or *Trochalopteron*—but they are characterized by their relatively small size and the sharply square-ended tail with narrow paler tips, the latter being red in three species. Four of the five *liocichlas*, the exception being the type species of the genus, have red outer edges at the tips of the tertials and secondaries, usually with a frayed effect; all have coloured wingpanels, and rather long rictal bristles and hind claw.

Five monospecific genera are united primarily by their small size and brilliant colours, particularly in the wings, but each has a distinctiveness that prevents it from being merged with another. The Bar-throated Minla (*Chrysominla strigula*) used to be treated in the genus *Minla*, but it is a larger bird, with a proportionately deeper, shorter bill, long rictal bristles and proportionately much longer, stronger tarsi, and also has a yellow crown and a very unusual pattern of neat barring on the throat. *Minla*, unusual for its sexual dimorphism in plumage, has a rather long thin bill and short rictal bristles, a head pattern and wingbar reminiscent of those of a *Pteruthius* shrike-babbler, and creeper-like habits. *Siva*, which has the size and bill shape of *Chrysominla*, has a squared-off tail with a narrow pale tip in a pattern that is reminiscent of the much larger *Liocichla*, and some of its subspecies have a bright cobalt wingpanel and uppertail quite unlike those of any other babbler. All three of these species share the *Liocichla* trait of white tips on the tertials and secondaries, setting them apart from the other two monospecific genera considered here. Nevertheless, the Red-billed *Leiothrix* (*Leiothrix lutea*) and the Blue-winged *Siva* (*Siva cyanouroptera*) have hybridized in captivity, confirming the reasonably close relationship that Cibois’s molecular work and, indeed, most taxonomic arrangements suggest. *Mesia* and *Leiothrix* are similar in several characters, including size, *Mesia* being slightly the larger, and red bill colour, rather long rictal bristles, yellowish-orange breast colour, a chestnut patch at the base of the folded primaries, yellow wing-fringing and greyish lower upperparts. *Leiothrix* even has a vestigially “silver ear”, but *Mesia* has a proportionately much larger bill and elongate silvery ear-coverts, while *Leiothrix* has a uniquely forked tail and elongate, white-edged uppertail-coverts.

*Crocias* is rather like *Cutia* in its pleasing oddness and in the difficulty of determining its systematic placement. Like *Cutia*, it

consists of two rather similar species that live high in the forest canopy. *Crocias* is a rather large, long babbler, grey-headed, brown-backed, white-bellied and with streaked flanks. Its deep strong bill has a hooked, notched tip, and it possesses medium-length rictal bristles and a long graduated tail.

The eight sibilas form a distinct group of specialized nectarivores. Without DNA details as a guide it is difficult to determine their placement within the babbler family, but, rather startlingly, molecular evidence puts them near *Leiothrix* and *Mesia*. The monospecific genus *Heterophasia*, which used to cover all the sibilas, is characterized by a rather long and slender decurved bill, medium-length rictal bristles, notably pointed wings, a very long tail twice the length of the wing and greatly graduated, and flocking behaviour, with no clear song. *Malacias*, with six species dressed in black, white, grey and/or brick-buff, is close to *Heterophasia* but with a rather shorter though same-shaped bill, slightly longer rictal bristles, a less pointed wing, a much shorter tail and a very different voice. *Leioptila*, with a single species, while sibia-like in size and shape, is less nectarivorous and its bill is less specialized, the rictal bristles are short, its song is less high-pitched, and it has a plumage resembling that of *Minla*.

The seven barwings in the genus *Actinodura* resemble the *Malacias* sibilas in size and tail length, but they form a still more uniform group, characterized by brown general coloration, dense black barring on the wings and usually the tail, erectile crown feathers, long rictal bristles, and a moderately strong but short bill. Molecular evidence places them near the minlas.

Towards the end of the sequence, there are six monospecific genera, three in Asia and three in Africa, which appear to be timaliid but about the relationships of which very little is known. *Myzornis* may be an offshoot of the small bright *Leiothrix*–*Minla*–*Siva* group, with which it has similarities in wing and tail patterns, or is perhaps derived from the sibilas, with which it shares a nectar-feeding habit and a relatively long decurved, albeit very thin bill. *Malia*, with the exception of the laughingthrushes the largest babbler, if indeed it is a babbler, is even more of a mystery, being unusually nondescript, with very short rictal bristles, short feathering to the base of the nostrils, short wings and a fairly long tail; the bill is rather long and straight but decurved at the tip, with a slight overhang, and the legs and feet are very strong. Although morphology is not, of course, the only consideration in terms of affinities and relationships, *Rhopophilus*, dis-

Previously more extensive, the genus *Garrulax* has contracted as a result of taxonomic revisions. As currently composed, it contains 15 species of Asiatic forests but even this group can be broken down into subgroups. One of these contains large species with pectoral colour-shifts and classic "laughing" songs or choruses. Another group has different vocalizations and a tendency towards pale throats, dark chest-bands, and white-tipped tails. A member of this latter group, the **White-throated Laughingthrush**, is a widespread species, occurring in a range of wooded habitats from Pakistan to south China.

[*Garrulax albogularis*,  
India.

cussed near the beginning of this section, shows no morphological characters that obviously debar it from membership of the Cisticolidae. It is, for example, a very close match in size, shape, colour and pattern for the Rufous-vented Prinia (*Prinia burnesii*), although its bill, legs and feet are all rather stronger.

In Africa, *Lioptilus* is outwardly like a small *Kupeornis*, the members of which used to be subsumed in *Lioptilus*, but it is relatively short-billed and short-legged, is frugivorous, and has a melodious song. It is, curiously, extremely similar in size and shape to *Mesia* and, while nothing like so colourful, it shares the reddish bill, black cap, lower-upperpart shading and central tail

colour of *Mesia*, and even has slightly silvery ear-coverts. As noted in the earlier paragraphs of this section, however, molecular evidence indicates that *Lioptilus* belongs near the Old World warbler genus *Sylvia*. Similarly, *Parophasma* may well be closer to the Old World warblers. It, too, sings beautifully, and it has the size and shape of a large *Sylvia*, such as the Orphean Warbler (*Sylvia hortensis*), although its bill is deeper and more hook-tipped, doubtless as a result of its berry diet. Its dull coloration and rufous-chestnut vent have together suggested a link to *Kupeornis*, but this seems less probable than does the sylviid option. The third and last of these monospecific African genera, *Horizorhinus*, has a bill much like that of *Parophasma*, rather powerful, deep and decurved to an overhanging tip, but its tarsi are longer and it has softer plumage, rather copious on the rump; its vocalizations again point to a possible link with *Sylvia*.

Molecular-genetic studies by Cibois and others indicate that the shrike-babbler genus *Pteruthius* should, in fact, be placed in the family Vireonidae. The five species in this genus are very divergent in size and coloration, but are united by the possession of a stout black hook-tipped bill, short rectal bristles, colourful plumage that is sexually dimorphic, a distinct juvenile plumage, a heavy-set body, slow arboreal movements, and simple monotonous songs. The monospecific *Erpornis*, once merged with *Yuhina*, has a slender bill with the tip slightly bent over, strong but short rectal bristles, a relatively prominent short crest, a squared-off tail, rather short and dainty legs and feet, and a tit-like call.

A suite of African monospecific genera, one genus with two species, and a single monospecific Malagasy genus, all of them long neglected in avian systematics but either certainly or probably not timaliids, conclude the sequence. Rich brown above and greyish-white below, *Kakamega* has been examined in detail by Mann and co-workers, who showed it to differ from the superficially similar *Illadopsis* in its very reduced rectal bristles, longer tongue and a host of minor anatomical details; before that, it was sometimes treated in *Trichastoma* and sometimes placed in the chat genus *Alethe*. The Spot-throat, too, has an intriguing history of generic allocations, in *Turdinus* to begin with; it is very similar in size, bill shape and proportions to *Kakamega*, its rump and tail are the same rich brown, and both species have a lightly maculate throat, although *Kakamega* has notably stronger legs and feet. The olive-and-yellow Dapple-throat, originally regarded

The genus *Melanocichla* contains two species of subtropical forests in the Sundaic region.

The **Black Laughingthrush** occurs in south Thailand, Peninsular Malaysia and Sumatra, while the closely related **Bare-headed Laughingthrush** (*M. calva*) is restricted to the mountains of north Borneo. Both these forms have dark plumage, short rectal bristles, pale reddish bills, and a distinctive whooping voice. The species pictured here has a patch of bare bluish-white skin behind the eyes, while the bare patch is yellowish in the Bornean form, and extended to cover much of the head.

[*Melanocichla lugubris*,  
Fraser's Hill, Malaysia.  
Photo: Morten Strange]

Two *Sundaic* laughingthrushes have chestnut on the head, prominent rictal bristles, bold white wing flashes, and relatively small, pale yellow-orange bills. One of these is the **Chestnut-hooded Laughingthrush** of Bornean highlands, previously considered conspecific with the **Spectacled Laughingthrush** (*Rhinocichla mitrata*) of Peninsular Malaysia and Sumatra. Both these forms inhabit humid shrubby areas and forest edge in the subtropical zone.

[*Rhinocichla treacheri treacheri*, Mount Kinabalu National Park, Sabah, Borneo.]

Photo: Leif Gabrielsen]

as a *Phyllastrephus* bulbul, is again of very similar proportions to *Kakamega*, and likewise with warm brown uppertail-coverts and tail and a lightly maculate throat. That molecular analyses should show these three genera, *Kakamega*, *Modulatrix* and *Arcanator*, to be related, as mentioned earlier in this section, seems entirely plausible.

In taxonomic terms, *Achaetops* is something of a mystery bird, thrown up by Namibia as a partner for the Herero Chat-flycatcher (*Namibornis herero*), the latter currently placed in the family Muscicapidae. Osteologically, it is indistinguishable from *Chaetops*, which it resembles quite closely in its upperpart streaking, fluffy rufous-chestnut rump feathers, bold white submoustachial line and petrophilous habits. On the other hand, it also resembles two sylviids, the Cape Grass-warbler (*Sphenoeacus afer*) and Moustached Grass-warbler (*Melocichla mentalis*), in certain aspects of its plumage and, in contrast to *Chaetops*, its song is a rich warbling and its gait a mouse-like run. Some features of its skull are timaliid, but it has been observed that *Sphenoeacus* itself may prove to be a babbler, rather than a warbler. *Chaetops* embraces two closely related, highly distinctive species, rather large, with powerful legs for hopping around rocky terrain. The genetic distinctiveness of *Chaetops*, and the fact that it is distinct in its behaviour and breeding biology, as well as structure, suggests that it merits placement in a family of its own.

Finally, *Mystacornis* is distinguished by its strikingly long, straight and rather narrow bill with a slight hook at the tip, its long tarsi with what are, for a ground-dweller, rather slender toes, its absence of rictal bristles, and the plush dense loreal feathering, as well as the fairly short wings and tail and, in the male only, a very bold head pattern. The single species is confined to Madagascar.

From the foregoing review, it could hardly be clearer that the taxonomy of the Timaliidae is far from being agreed upon and stable. Even if it were much clearer which genera are truly timaliid and how they fit together, there is still the matter of species limits. Since the start of the twenty-first century, a considerable amount of revision of species limits has been carried out, this based mainly on simple morphological and/or geographical parameters, but there is certainly more to be done involving the combination of morphological, vocal, behavioural and molecular information.

## Morphological Aspects

Babbler plumage varies from being rather hard to being soft and lax, and in many species the back, rump and sometimes flank feathering tends to be soft and profuse. Some species have modifications, especially on the forecrown, and the ear-coverts are frequently lightly streaked or in some way differentiated, even if only slightly, from the surrounding colour. The skin is of medium toughness. Rictal bristles are present, usually not exaggerated, and sometimes very inconspicuous. The wings are short and rounded, with ten primaries; the outermost primary, P10, is

Three species of large babbler bear a superficial resemblance to Turdoides in their streaky brown, buff and grey plumage, or to Pomatorhinus in their large, graduated tails and decurved bills. They are grouped together in the genus *Babax*, and occur mainly in the eastern Himalayas. The **Chinese Babax** inhabits open broadleaved evergreen forest, forest edge, secondary growth, tall grass, and bamboo, in the mountains of north-east India, north Myanmar, and south China. The distinctive form woodi, seen here, may be a separate species.

[*Babax lanceolatus woodi*, Mt Victoria, Myanmar. Photo: Robert Hutchinson/ Birdtour Asia]

30–70% shorter than the longest, and the outermost primaries are often notably decurved. Except in the genera *Spelaornis* and *Pnoepyga*, the tail has twelve feathers, and is usually relatively long, often fairly to strongly graduated, or rounded but with the outermost rectrix shorter than the others. The bill is generally rather robust but not very deep, sometimes notched at the tip of the upper mandible, with the culmen often slightly decurved, but bill shape and size are highly variable within the family. The legs and toes are sturdy, with a scutellate tarsus, the leg muscles being well developed. The iris is much more frequently pale than is the case with most other passerine families. The syrinx lacks the "turdine thumb" which helps to characterize the thrushes and chats of the family Turdidae and the Old World flycatchers, the Muscicapidae. The stomach of those few timaliids for which relevant information is available, for example the Orange-billed Babbler (*Turdoides rufescens*), the Brown-capped Babbler (*Pellorneum fuscicapillus*) and, on a British Natural History Museum label, the Red-billed Leiothrix, is very muscular.

"Tit-babbler", "wren-babbler", "laughingthrush", "wren-tit", "thrush-babbler", "jay-thrush", "shrike-babbler", "flycatcher-babbler"—these English vernacular names capture something of the morphological diversity of the babbler radiation, indicating how some of the taxa have filled niches or developed characters that European ornithologists associate with more familiar species, but they fall well short of doing it full justice. In terms of size, colour, pattern and shape, all of which reflect the great variety of niches and habitats, from desert fringes to deep rainforest, that the timaliids occupy, the variation to be found in this one family is unusually high and, taken as a whole, is probably unmatched by any other in the class Aves.

The smallest members of the family are the sensational Visayan Miniature Babbler (*Micromacronus leytenis*) and its twin, the Mindanao Miniature Babbler (*Micromacronus sordidus*), creatures that, at 7–8 cm in length and weighing as little as 5.5 g, are so tiny that, hummingbirds (Trochilidae) aside, they come close to being the smallest birds on earth, rivalling the Pygmy Tit (*Psaltria exilis*) of Java. The largest babbler, by way of contrast, is the Greater Necklaced Laughingthrush (*Garrulax pectoralis*), which, at 34.5 cm and up to 170 g, just exceeds the Giant Babax (*Babax waddelli*) in length and weight and is 30 times the weight of *Micromacronus*. Between these extremes there is a fairly steady

Five small, nondescript, slender-billed, lightly streaked species are placed in the genus *Strophocincla*. The **Streaked Laughingthrush** is typical of this group, not only because it is generally reddish-brown, but because its distribution is centred on the Indian Subcontinent. It inhabits a variety of scrub and cultivation types in the Himalayan montane zone, sometimes ascending to near 4000 m. The two southern Indian *Strophocincla* are somewhat more uniform, and have relatively long rictal bristles; it may prove necessary to erect a separate genus for these forms.

[*Strophocincla lineata lineata*,  
Naini Tal, India.  
Photo: Ketil Knudsen]

continuum in sizes, with other tiny species such as the two pygmy babblers in *Sterrhoptilus* and the virtually tailless *Pnoepyga*, and other fairly hulking laughingthrushes in *Garrulax*, *Babax*, *Grammatoptila* and *Dryonastes*, along with *Malia* and the larger *Turdoides*. As a rule, all of these birds tend to be rather heavier-bodied and chunkier, with proportionately stronger bill and legs, than species of similar dimensions in the families Turdidae, Muscicapidae and Sylviidae.

Matching the wide variation in size is a similarly wide variation in colour. Many species are, however, rather plain and cryp-

The **Plain Laughingthrush** inhabits scrub, thickets, and moor-like terrain at medium altitudes of 1600–3300 m in Asian mountains. As its name suggests, it is unremittingly non-descript. In this regard it is similar to its only congener in the genus *Pterorhinus*, the White-browed Laughingthrush (*P. sannio*), which also has a global range centred on China. These two forms are united by their distinctive vocalizations and dull plumage, but differ in bill morphology.

[*Pterorhinus davidi davidi*,

Holmes]

tic, perhaps none more so than the mainly dull brown *Trichastoma*, *Malacocincla*, *Pellorneum* and *Malacopteron* babblers of forest undergrowth in South-east Asia and the Sundaic region, although the *Malacopteron* species, inhabiting the lower to middle storey, are notably more countershaded, with paler underside, than are the others. The eight wren-babbler genera *Spelaornis*, *Elachura*, *Pnoepyga*, *Kenopia*, *Turdinus*, *Gypsophila*, *Napothera* and *Rimtor*, together with the formerly named wren-babblers in *Sphenocichla*, *Robsonius* and *Ptilocichla*, possess streaked or scaled, barred or spotted upperparts and, usually, closely patterned underparts with little countershading, all in various mixes of brown, rufous, black, grey, buff and white to match and merge with the complex low vegetation that they inhabit at the edges and in the interior of forest. The "nun-babblers" of the genus *Alcippe*, with their grey head, brown upperparts and buff underparts, are bewilderingly understated. Always excepting the spectacularly distinctive white-and-black Southern Pied Babbler, the genus *Turdoides* consists of brown, rufous, buff, grey, blackish and whitish species, with varying amounts of cryptic streaking, inhabiting arid landscapes.

The laughingthrush genera *Babax*, *Strophocincla*, *Stactocichla* and *Leucodioptron* and the intriguing African *Ptyrticus* are similarly coloured, but with bolder patterns of streaks and spots, while such genera as *Pomatorhinus* and *Stachyris* combine a sometimes strong black-and-white head pattern with concealing browns and rufous, leading to still more richly camouflaged plumages in the densely patterned barwings (*Actinodura*), and reaching apotheosis in the wonderful Giant Laughingthrush (*Ianthocincla maxima*) and Spotted Laughingthrush (*Ianthocincla ocellata*). The colours and patterns of these latter species seem far too striking to be cryptic, but in context the spots and bars and patches of rufous and black clearly have a disruptive effect on the birds' outline. This may be true of many of the other laughingthrushes in the genera *Ianthocincla*, *Garrulax*, *Dryonastes* and *Trochalopteron*, for their many and various beautiful splashes of colour—black, white, chestnut, golden-yellow, rufous, crimson—are not so bold at any distance beyond close range as to make them stand out. Only a few species, such as the White-crested Laughingthrush, the Black-and-white Laughingthrush (*Garrulax bicolor*), two *Gampsorhynchus* babblers and the Southern Pied Babbler, have evolved an aposematic conspicuousness, for which their

aggressiveness and strength of numbers doubtless compensate. Other brightly coloured species, such as the sibilas, the Blue-winged Siva, the minlas and cutias, the Fire-tailed *Myzornis* and the shrike-babblers, all tend to deploy white, yellow or green to countershade and camouflage the sharper patterns.

A feature of several babblers is a long blackish lateral crownstripe, present in several genera. Thus, it is exhibited by the Crimson-faced *Liocichla* (*Liocichla phoenicea*), the Blue-winged Laughingthrush (*Trochalopteron squamatum*), the Striated Laughingthrush (*Grammatoptila striata*), the Striped Wren-babbler (*Kenopia striata*), the Taiwan Yuhina (*Yuhina brunneiceps*), most *Schoeniparus* and *Alcippe* fulvetas and, incidentally, several species of parrotbill, these last currently separated in the family Paradoxornithidae. Another feature, much more prevalent, is the wingpanel produced by bright colour or colours, often two or three in sharp contrast, on the outer webs of the flight-feathers, and often combined with strongly coloured wing-coverts. This is a character shared by many species in many genera, which include *Lioparus*, *Yuhina*, *Schoeniparus*, *Pseudominla*, *Cutia*, *Garrulax*, *Grammatoptila*, *Rhinocincla*, *Ianthocincla*, *Trochalopteron*, *Liocichla*, *Chrysominla*, *Minla*, *Mesia*, *Leiothrix*, *Crocias*, *Heterophasia*, *Malacias*, *Leioptila*, *Siva*, *Actinodura* and *Myzornis*, and with traces in *Chrysomma*, *Macronous*, *Stachyris* and even one species of *Kupeornis*. Again, this feature is exhibited, very notably, by most species of parrotbill.

There are various other particular plumage ornamentations in the family. Several species have a crest, in all cases erectile, and these include the two yuhina genera *Yuhina* and *Staphida*, the Striated, White-crested and Black-and-white Laughingthrushes, the Hoary-throated Barwing and the White-bellied *Erpornis*; the Bar-throated Minla is "half-crested", with ragged crown feathers. Several species of laughingthrush have plush or bristly feathering on the forecrown, and a few have bare peri-orbital or postocular skin. The Yellow-eyed Babbler (*Chrysomma sinense*) has a bold orange eyering. Various genera, including *Pomatorhinus*, *Mesia*, *Leiothrix* and *Gampsorhynchus*, sport a bright red, orange or yellow bill. The Spiny Babbler has enlarged and pointed feather shafts on the back and, especially, the breast, so that its plumage really is spiny, and the Fluffy-backed Tit-babbler and several others in its genus have profuse soft rump feathering with long bare white shafts, a feature shared

*Trochalopteron*, with 16 species, is one of the most speciose timaliid genera. Its members are characterized by small bills, scaling on the body plumage and wingpanels formed by contrasting fringes to the remiges.

These features are demonstrated here by **Elliot's Laughingthrush**, a species of thickets, undergrowth, bamboo, open forests and gardens in an unusually wide altitudinal range of 1000–4200 m. The epicentre of the *Trochalopteron* radiation is in the Himalayas, especially the eastern Himalayas, but some forms occur as far afield as Taiwan.

[*Trochalopteron ellioti*, Zhuokeji, Sichuan, China.  
Photo: John & Jemi Holmes]

Of the five *Liocichla* species, only two have red faces, and both were previously treated as *Garrulax* or *Trochalopteron* laughingthrushes. They are the **Scarlet-faced *Liocichla***, a beautiful species from the mountains of South-east Asia, and **Crimson-faced *Liocichla*** (*L. phoenicea*); the two were only recently split. All members of the genus are relatively small with distinctly square-ended tails, coloured wingpanels, prominent long rectal bristles and long hind claws; four of them have red outer edges at the tips of the tertials and secondaries, as seen here.

[*Liocichla ripponi ripponi*, Doi Lang, Chiang Mai, Thailand.  
Photo: Kanit Khanikul]

with *Micromacronus*. The Flame-templed Babbler (*Dasycrotopha speciosa*) has curious head-tufts which may project more in agitation.

Although not part of the plumage, mouth colour appears to be important in some species. It is yellow in Sharpe's Babbler (*Turdoides sharpei*) and black with a yellow tongue in the Brown Babbler (*Turdoides plebejus*). In the case of the Yellow-eyed Babbler, it is black in the breeding period but otherwise brownish. The extent of this condition and its function are, however, unknown.

Most babblers are what would be considered "normal" in proportions, but the trend towards a long, graduated tail reaches a climax with the Long-tailed Sibia (*Heterophasia picaoides*) and generally with the laughingthrushes, in which the character is all the stronger for the shortness of the wings. The Red-billed Leiothrix, however, has a forked tail and the *liocichlas* have a rather squared-off tail. As the tail becomes shorter, so the profile becomes more rounded and chunkier, as in the genera *Stachyris*, *Turdinus* and *Napothera*, and then stubby and wren-like, as in the almost tailless *Rimator* and *Pnoepyga*.

Variations in bill size are just as strong. Among species that take a variety of invertebrates, seeds and fruit, the bill is relatively simple, a generalist tool used mostly for probing, digging, flicking and plucking, although its size, of course, co-varies with the size of the bird itself. Others timaliids are more specialized, and the English names invoked to describe them now or in the past, "wren", "tit", "shrike" and "jay", reflect these adaptations. Certain laughingthrushes have a stout bill like that of a jay (*Corvidae*), used for hoarding and hammering acorns, and the anomalously stout bill of the Striated Laughingthrush may prove to serve a similar function. While many wren-babblers recall the wren genus *Troglodytes*, the analogy for *Rimator*, with its long and thin curved bill, is perhaps the cactus-wren genus *Campylorhynchus*. The *Pomatorhinus* scimitar-babblers, so aptly named, have for a bill a "scimitar" that resembles the bills of the New World *Toxostoma* thrashers; that of the closely related Sickle-billed Scimitar-babbler (*Xiphirhynchus superciliaris*) brings to mind a Neotropical woodhewer (*Campyloramphus*), although the former feeds mostly on the ground. The genus *Sphenocichla* has a conical bill like that of some of the caciques (*Cacicus*), and presumably utilizes it for chiseling. The short decurved bills of

*Myzornis* and the *Heterophasia* and *Malacias* sibilas are adaptations for nectar-feeding, and these timaliids have developed brush-tipped tongues as a consequence of this behaviour.

Differences between the sexes of babblers are mainly morphometric, with females almost invariably a little smaller than males, although this is only an average and there is plenty of overlap. Only about 8% of the 309 species in the present treatment of the family exhibit any sexual plumage differences, and some of these, such as the paler or duller underparts of females of *Lioparus* and *Micromacronus*, are minor. The genera *Cutia*, *Mesia*, *Leiothrix*, *Minla*, *Myzornis* and *Pteruthius* are well known for their fairly marked differences between the sexes, but the constantly warmer underparts of female *Spelaornis* babblers and the generally less pronounced colours of female *Liocichla* have been less often recognized, although a recent study of the Taiwan *Liocichla* (*Liocichla steerii*) has demonstrated that some differences show up spectographically. The Blue-winged Laughingthrush has the distinction of being the only "garrulacine" in which plumage dimorphism is apparent, the female being more rufescent on the face and having dark brown, rather than blackish, flight-feathers and tail. Among the "non-babblers" (see Systematics), *Achaetops* and *Chaetops* exhibit small differences between the sexes and *Mystacornis* shows large differences.

As already noted (see Systematics), it is one of the general taxonomic diagnoses of babblers that there is usually no distinct juvenile plumage. In some species, the similarities may be bewilderingly strong. For example, juvenile Grey-cheeked Fulvetta (*Alcippe morrisonia*) are so like the adults that, in one study of the species, the only reliable guide to ageing proved to be the degree of pneumatization of the skull in the period April–September, when the skulls of 93% of known juveniles were incompletely ossified and those of 93% of known adults were fully ossified, although adults tended to show redder eyes. Soon after fledging, however, juvenile timaliids can usually be distinguished in the hand from adults by their softer, less pointed flight-feathers, particularly the first primary. Even so, it is an exaggeration to suggest that there is no difference between adults and juveniles. The great majority of juveniles exhibit minor distinctions which reveal their age, most often simply being browner than their parents, and sometimes having slightly darker eyes. A notable example of more distinctive plumage is the rufous stain on

The **Red-tailed Minla**, sole occupant of the genus *Minla*, is a strikingly patterned timaliid with a warbler-like bill and creeper-like foraging behaviour. It extends from Nepal to Vietnam, occurring in all strata of montane evergreen forests, but most often found with mixed-species flocks in the canopy. It is weakly sexually dichromatic, the female having a more olive-grey mantle, and more yellowish fringing on the tail and wings, than the male (shown here).

[*Minla ignotincta*.  
Photo: Cyril Laubscher]

the head of immature White-hooded Babblers (*Gampsorhynchus rufulus*) and another is the occluding grey feathering of young Southern Pied Babblers, but these are rare instances.

Very limited data are available on the moult of the family. There is a post-juvenile moult, which starts some weeks or months after fledging. It is completed rapidly by the smaller species but much more slowly by larger ones, and adverse weather will cause it to be suspended. For example, Yellow-billed Babblers (*Turdoides affinis*) begin to moult three months after fledging, but, whereas individuals that fledge in the early part of the year are able to complete this moult, later-fledged ones cannot and, instead, undergo a complete moult in the following year. Similarly, in the case of Palearctic *Turdoides* babblers, early-hatched young complete the moult before winter, but later-hatched ones may replace only some flight-feathers and tail feathers before full suspension of the moult in the later part of the autumn. Adult Yellow-billed Babblers and Jungle Babblers (*Turdoides striata*) may nest and moult simultaneously, the body feathers being replaced from March to November and the flight-feathers from May to November. Similar extended moults occur in the Arrow-marked Babbler (*Turdoides jardineii*) in the Afrotropics. This may entirely reflect the piecemeal nature of the breeding cycle and the high number of renesting attempts that can be made. On the other hand, the moult of the Red-billed Leiothrix, at least in captivity, can be very fast and be completed in less than a month.

### Habitat

Forest, forest edge, scrub and grassland are the habitats of babblers. While the family can be said, therefore, to occupy a broad spectrum, from primary forest down to open climax vegetation below human eye level, which suggests a very plastic ecological adaptability, in reality the great majority of babblers appear, nevertheless, to be birds of dense thickety areas such as are found at treefalls or edges in standing forest or else, in drier open areas, in clumps of trees and bushes and tangles. The habitat occupied by members of this family has in many cases not been well defined, and for almost no timaliid species has it been quantified, so that the descriptions given in the literature often reflect very crude, broad impressionistic assessments of general usage, with little or

no precise indications of the key features to which the species are adapted. Some species are described as occurring simply in "forest", and, although most descriptions give considerably more detail than this, it is merely of an additive type. It is not that such accounts are inaccurate, but how helpful they are in indicating the species' true habitat preferences is open to query.

Nevertheless, if we break down these descriptions very crudely indeed into those which indicate habitat simply as (1) forest only, (2) forest, secondary growth and some or sometimes more open adjacent areas ("forest and edge"), (3) forest edge, young secondary growth, plantations and scrub ("forest edge"), (4) scrub and secondary growth ("scrub") and (5) tall grassland and scrub ("grassland"), we find that 22% of babblers are confined to forest, 10% to forest and edge, 56% to forest edge, 10%

The sibilas form a group of eight specialized nectarivores, six of which are currently placed in the genus *Malacias*. The **Rufous Sibia**, a delicately coloured inhabitant of Himalayan forests, is a typical example. It has a long graduated tail, the short legs of an arboreal passerine, and the slender decurved bill of a nectar-hunter. In terms of plumage, sibilas vary from black and white, to grey or rufous. Their taxonomic placement in the family is debatable, but preliminary results of genetic analyses suggest, rather surprisingly, that they may be most closely related to Leiothrix and Mesia.

[*Malacias capistratus bayleyi*,  
Hanuman Tok,  
Gangtok, Sikkim, India.  
Photo: Gaurav Bhatnagar]

The barwings are a well-defined group of seven Asian species in the genus *Actinodura*. The results of genetic analyses suggest a relationship with minlas. They resemble sibilas in size and tail length, but differ in the dense black barring on their wings and tails, erectile crown feathers, long rectal bristles, and shorter, deeper bills. Most barwings have brown plumage, with a varying amount of streaking, and a greyer head. They also tend to have pale eyerings, a trait expressed most conspicuously in the **Spectacled Barwing**.

[*Actinodura ramsayi*

to scrub and 2% to grassland. If we then allow that the plain use of "forest" seems frequently to be a default designation based on the simplest level of information or assumption, and we arbitrarily decide that half of such designations may in due course be reclassified under "forest and edge", then we can speculatively group all the species into a more general arrangement in which 11% are true forest species, 77% are broad edge-spectrum species, and 12% are scrub and grassland species. Time will tell whether this overemphasizes the basic ecological character of babblers, but generally it seems to reflect their specialization for foraging in dense, relatively low-level vegetation such as luxuriant thickets, regenerating edges, dense undergrowth and lower storeys, the often rather stout bill and legs being adaptations for moving about in the woodier, more sclerotic parts of the forest and taking wingless or immobile animal food from more solid substrates such as stems, branches, dead leaves and the ground (see Food and Feeding). If babblers are thus specialized on disturbed and secondary habitats, this may help to explain why so few of them are threatened (see Status and Conservation); and, if they occur also in forest canopy and dense grass, these appear to be relatively unsuccessful or narrowly specialized colonizations by species which still retain the skulking disposition of their thicket-dwelling forebears.

Among these slightly unusual babblers, those that occupy largely the upper strata of the forest are the five *Pteruthius* shrike-babblers, which are not, in any case, true babblers, the two cutia species, the two species of *Crociis*, the two *Micromacrus*, the three *Kupeornis* mountain babblers and, being partly nectarivorous, most of the *Yuhina* species, although some of the last-named habitually forage at lower levels and all are capable of doing so. The *Heterophasia* and *Malacias* sibilas are also partially dependent on nectar and use the undercanopy, as does the Rufous-backed Sibia (*Leioptila annectens*), although it is not known to take nectar and is more bound to moss-laden and lichen-covered branches. The Panay Striped Babbler (*Zosterornis latistriatus*) likewise exploits mainly the upper levels of the forest, although in moss forest this is presumably relatively low down. All of these species are montane, some shrike-babblers appearing at only 300 m but most doing so at much higher elevations, and all except the yuhinas specialize in foraging on the moss-laden and lichen-covered trunks and branches of the upper layers of the forest.

Those timaliids that largely occupy grassland areas include the *Chrysomma* species, which skulk in tall grass, reedbeds and tangled thickets, living in extensive tracts of habitat. Jerdon's Babbler (*Chrysomma altirostre*) is the most specialized in this regard, and has a strictly lowland distribution, whereas its sole congener, the Yellow-eyed Babbler, ranges higher, to around 1500 m, and the apparently closely related Rufous-tailed Babbler (*Moupinia poecilotis*) starts at 1500 m and continues to 3300 m, occasionally up to 3700 m. The Marsh Babbler is unusual in its genus, *Pellorneum*, for inhabiting reeds and tall grasses near water, and both the Striated Babbler (*Turdoides earlei*) and the Slender-billed Babbler (*Turdoides longirostris*) similarly occupy grassland, usually near water, as their major habitat type, although both retain the trait of their genus of using scrubby bushes and trees for nesting. Other *Turdoides* babblers use savanna and forage in grassy areas, but these are birds less of the grasslands than of the scrub and trees that dot the grasslands. Three anomalous southern African species in the genera *Achaetops* and *Chaetops* live in rocky and sometimes shrubby terrain in grassland areas, and may therefore crudely be considered "grassland" species.

Since bamboo is a type of grass, this is the appropriate place to mention three bamboo specialists in the family, although in the present classification they fall into the category of forest-edge species. These are the curious Golden-breasted Fulvetta (*Lioparus chrysotis*), which is usually found in bamboo although also in bushes bordering tracks; and the even more curious pair of *Gampsorhynchus* babblers, namely the White-hooded and Collared Babblers (*Gampsorhynchus torquatus*). *Lioparus* is montane in its distribution, *Gampsorhynchus* keeping to foothills and submontane areas. Other babblers that display a strong degree of association with bamboo, although no such relationship is an obligate one, are the Sickle-billed Scimitar-babbler, the Orange-billed (*Pomatorhinus ochraceiceps*) and Coral-billed Scimitar-babblers (*Pomatorhinus ferruginosus*), and the Golden-fronted Fulvetta (*Pseudominla variegaticeps*), again all submontane to montane species. Many other members of the family include bamboo in their habitat and at least occasionally use it or visit it.

Babblers that inhabit what is here loosely termed "scrub"—various vegetation types in which trees do not form continuous stands but, at best, occur in small clumps—are relatively few in number, and half of them belong to the genus *Turdoides*, sug-

Apart from the fact that it is incontrovertibly a babbler, the evolutionary origins of the **Fire-tailed Myzornis** remain obscure. It may be derived from the small, bright species in the *Leiothrix*-*Minla*-*Siva* group, or it may be related to *sibias*, with which it shares a foraging specialization (nectarivory) and a related adaptation (decurved bill). The sole member of the genus *Myzornis*, it roams in small flocks through mossy scrub, bamboo, and low forest in the Himalayas of Nepal, northern India, Bhutan, south China and north Myanmar, occasionally ascending above 4000 m.

[*Myzornis pyrrhura*,  
Dochula, Buthan.  
Photo: Yeshey Dorji]

gesting that this type of habitat does not greatly favour birds with the limited vagility of the Timaliidae. Four monotypic genera, *Chamaea*, *Dumetia*, *Timalia* and *Rhopophilus*, are among them. Each of these four is difficult to characterize. The Wrenit basically requires low brush and scrub, but this can occur independently of any trees as well as inside many different types of open wooded landscape. The Tawny-bellied Babbler (*Dumetia hyperythra*) is rather similar, using low scrub and grass but seeming to need a certain amount of taller cover. The Chestnut-capped Babbler (*Timalia pileata*) occupies an intriguing range of open habitats, from swampy reeds and grasses to bamboo, thorn hedges, brushwood and palm bushes in mangroves. The last of the four, the Chinese Bush-dweller, utilizes scrub, bushes, grass and reeds. A fifth species, the Spot-throated Babbler (*Pellorneum albiventris*), an odd *Pellorneum* closely related to the Marsh Babbler, uses scrub, grass and pine-forest undergrowth. The bush-dweller's elevations are not well documented, but the other four range from sea-level to between 1500 m and 2300 m. All five species are small-bodied in comparison with the rest in this habitat group.

Ten laughingthrushes fall into the scrub-dwelling category. The Masked Laughingthrush, which occupies scrub, thickets, bamboo, reeds and hedges from the lowlands to 1000 m, is the only member of the genus *Garrulax* to do so, while the other nine are divided among three genera which exploit exclusively this habitat. The Chinese Hwamei and the Taiwan Hwamei (*Leucodioptron taewanum*) favour clumps of secondary growth, thickets, bamboo, tall grass and sometimes gardens, from the lowlands to 1200–1800 m. The five small *Strophocincla* laughingthrushes inhabit streamside thickets, wooded gardens, bushy field margins and forest edge at middle elevations, roughly 1000–2500 m. Both of the *Pterorhinus* species occupy willow (*Salix*) scrub, grass, thickets, brushwood and dwarf open forest, at varying elevations, the White-browed Laughingthrush (*Pterorhinus sannio*) from low foothills to 2600 m and the Plain Laughingthrush (*Pterorhinus davidi*) at 1600–3300 m.

This, then, leaves a large number of *Turdoides* babblers as "scrub"-dwellers, birds that occupy dry thorny open country from semi-desert with palm groves and date gardens to open savanna and scrubby hillsides with boxthorn (*Lycium*) and acacia (*Acacia*), tamarisk (*Tamarix*) and *Ziziphus* clumps. They include the Spiny, Iraq (*Turdoides altirostris*), Common (*Turdoides caudata*), White-throated (*Turdoides gularis*), Large Grey (*Turdoides*

*malcolmi*), Arabian (*Turdoides squamiceps*), Fulvous, Bare-eyed, Rusty, Sharpe's, Arrow-marked, Scaly (*Turdoides squamulata*), Northern White-rumped (*Turdoides leucopygia*), Southern White-rumped (*Turdoides hartlaubii*), Hinde's Pied (*Turdoides hindei*) and Northern Pied Babblers (*Turdoides hypoleuca*). While the Spiny Babbler occurs at 915–2135 m, Hinde's Pied Babbler at 1070–1700 m, the Northern White-rumped Babbler at 1250–2450 m and reaching to the foothills in Eritrea, and the Northern Pied Babbler at 1000–1800 m, the others range down to sea-level. At the other extreme, the Arabian Babbler ascends to 2800 m in

Recent molecular work has shown that the *Pteruthius* shrike-babblers are not babblers at all, and belong instead to the corvid lineage. Genetic data further suggest that they are so close to the vireos (*Vireonidae*) of the New World that they should be included within that family. While this discovery is startling from a biogeographical and morphological perspective, it is less surprising from the viewpoint of voice and behaviour as species like the **White-browed Shrike-babbler** do indeed act and sound vireo-like. This is a common treetop species across much of Asia from Pakistan to Java and Borneo.

**The White-bellied Erpornis**, previously placed in Yuhina, is another widespread Asiatic form that has been shown to be misplaced in Timaliidae, and more accurately allied with the Vireonidae. Sole member of the genus Erpornis, it has a slender bill, a relatively prominent crest, a square-ended tail, and rather weak legs and feet. In its foraging behaviour and vocalizations it is somewhat reminiscent of tits (Paridae). Fairly common in the middle strata of humid forests, it occurs from Nepal to Sumatra and Borneo, ranging from the lowlands to the montane zone, and occasionally reaching 3500 m.

Yemen, much higher than any other *Turdoides* babbler, the next highest elevation being reached by the Northern White-rumped, at 2450 m.

Species that seem most simply characterized as forest-edge inhabitants comprise those that occupy glades and light-gaps, range out into more open country and are reported also, at least marginally, from forest itself, but with the main emphasis and evidence falling on edge habitats, which here include also secondary and recovering forest, gallery and riverine forest, and plantations such as coffee and timber trees. In the Timaliidae, such species are represented by a wide range of genera and well over half of all members of the family. In Africa, this involves both species of *Pseudoalcippe*, most, if not all, of the *Illadopsis* species, seven *Turdoides* and the monospecific genera *Lioptilus*, *Paraphasma* and *Horizorhinus*.

One of these species, the Scaly-breasted Illadopsis (*Illadopsis albipectus*), is perhaps the only babbler to have been the subject of detailed quantitative analysis of habitat selection. This study, carried out by J. A. Lindsell in Budongo Forest, in Uganda, generated some very interesting insights. The species preferentially forages in and adjacent to treefall gaps in natural forest, probably because the decaying wood within the gaps is associated with a higher biomass of leaf-litter invertebrates, on which the birds mainly feed, although this is true also in man-made light-gaps where fallen timber is usually removed. Territory density increases with the number of light-gaps, so that the highest densities are found in forest that has been well logged. Intriguingly, however, while individuals having home ranges with a higher number of treefall gaps are in better body condition than are others, they also experience a greater squeeze during the main annual dry season. Because it is more open, the understorey of logged forest is subject to more extreme seasonal abiotic conditions, and in the dry season becomes lighter, hotter and less humid than does unlogged forest, food being accordingly less easy to find. Another member of the genus, the Brown Illadopsis (*Illadopsis fulvescens*), is interesting not only for being able to use pure stands of arrowroot (Marantaceae), but also for having a strong requirement for primary forest in the Lower Guinea forests while readily tolerating disturbed and logged forest in the Upper Guinea region.

This difference in tolerance on a broad geographical scale appears to have been recorded for only one other babbler, the Crimson-faced Liocichla. Like all other species in its genus, this is essentially a bird of edge habitats at middle elevations, but in Bhutan, and presumably throughout the westernmost reaches of its range, it occurs only in extensive tracts of untouched broadleaf forest. It is perfectly possible, of course, that similar conditions apply among other species but have not yet been registered by ornithologists. Another species, the Orange-billed Babbler of south-west Sri Lanka, has a curious trait of seeming to be restricted to primary forest in some areas while entering secondary areas, scrub and tea plantations in others; this and the Jungle Babbler are the two Asian *Turdoides* that qualify as "forest-edge" species as defined here.

Three of the six genera confined to the Philippines, *Dasycrotapha*, *Sterrhoptilus* and *Zosterornis*, consist largely of forest-edge species, although the Panay Striped Babbler is perhaps better classified as an undercanopy forest bird (see above). The Golden-crowned Babbler has been reported as preferring forest with more than 90% canopy cover but with a dense understorey covering up to 90% of the forest floor, suggesting that this species is, in fact, a treefall-gap specialist, which in the present treatment counts as forest-edge habitat. *Dasycrotapha* and *Sterrhoptilus* species cover elevations from around 100 m to well past 1000 m. *Zosterornis* taxa are typically found higher up, mainly or exclusively above 1000 m, the Chestnut-faced Babbler (*Zosterornis whiteheadi*) ranging occasionally down to 100 m but becoming abundant above 1400 m in moss forest, which has the general broken-canopy, heavily tangled character of forest edge.

Members of the genus *Macronus*, which has three species represented in the Philippines but is chiefly Sundaic in range, also occupy forest-edge habitats, as do the mainly Sundaic genera *Malacocincla* and *Trichastoma*. *Macronus* species have lowland distributions, although one reaches as high as 1700 m, but upper elevational limits in all cases may reflect attenuated populations and probably the highest densities all occur well below 1000 m. This is true of *Malacocincla* and *Trichastoma*, too, the highest record of the former also being at 1700 m, and that of the latter at 1900 m. These species' dependence on disturbed for-

est areas has allowed them also to colonize low-stature climax forest such as peatswamp-forest, upland and coastal heath-forest, mangroves and nipa palm (*Nypa*) swamps. The White-chested Babbler (*Trichastoma rostratum*) is perhaps the most specialized of them, being very largely a bird of forested riverbanks.

Babblers in *Pellorneum* and *Malacopteron*, two genera taxonomically and distributionally closely associated with *Malacocincla* and *Trichastoma*, being similarly plain and brown in basic coloration, mainly lowland in elevational range, and preponderantly Sundaic albeit extending well to the north and west, are similar to each other in ecology. Apart from the two anomalous species in grassland and scrub, respectively, *Pellorneum* consists of babblers which are clearly main users of forest-edge habitats, although at least one species, the Black-capped Babbler (*Pellorneum capistratum*), reacts badly to the fragmentation of its forest habitat. *Malacopteron*, on the other hand, combines obvious forest-edge species such as the Sooty-capped Babbler (*Malacopteron affine*) and Melodious Babbler (*Malacopteron palawanense*) with ones that appear to prefer less disturbed formations, namely the Moustached Babbler (*Malacopteron magnirostre*), Scaly-crowned Babbler (*Malacopteron cinereum*) and Rufous-crowned Babbler (*Malacopteron magnum*).

*Stachyris* is a further genus largely tied to the Sundaic lowlands, but, as with *Malacopteron*, it contains both forest-edge and forest-interior species, as well as ones that appear to bridge both habitat types. The most anomalous *Stachyris* in terms of plumage—the primary feature of which is its lack of plumage characters—is also the most specialized. This is the Sooty Babbler, which is one of two timaliids, the other being the Limestone Wren-babbler (*Gypsophila crispifrons*), confined to forest growing on limestone outcrops, although a third species, the Streaked Wren-babbler, is commonly, but not always, found in such areas. A second apparent specialist is the White-necked Babbler (*Stachyris leucotis*), which is believed to be confined to forest on slopes throughout its range, although nowhere reaching above 1000 m. In contrast, at least five species have frequently been recorded in old rubber and/or *Albizia* plantations, and evidently qualify as forest-edge inhabitants. These are the Black-throated Babbler (*Stachyris nigricollis*), Grey-headed Babbler (*Stachyris poliocephala*), Grey-throated Babbler (*Stachyris nigriceps*), Chestnut-winged Babbler and Chestnut-rumped Babbler (*Stachyris maculata*), and it seems likely that all the other members of the genus fall into this category, although one, the White-

bibbed Babbler (*Stachyris thoracica*), is not sufficiently well known to be described as other than a forest species. With regard to any assumptions about these birds' ability to survive away from forest, however, an interesting and potentially important proviso is supplied by the White-breasted Babbler of Java. This species has been found to occur in highly disturbed areas, including the edges of damar (*Agathis*) plantations, but it seems to do so only when these are adjacent to primary forest.

Among the other small babblers that can be categorized as forest-edge species are five of the seven *Alcippe*, all three *Schoeniparus*, the closely related monospecific *Rhopocichla*, all four *Stachyridopsis* and three of the four *Pseudominla* species. Grey-checked, Nepal (*Alcippe nipalensis*), Black-browed (*Alcippe grotei*), Brown-cheeked (*Alcippe poiocephala*) and Brown Fulvetta (*Alcippe brunneicauda*) occupy forest, secondary growth, bamboo and scrub, the first two with a fairly broad elevational range of 200 m to at least 2500 m, the second two confined below about 1500 m; in parts of Indochina, the Black-browed Fulvetta is segregated altitudinally from the higher-ranging Mountain Fulvetta (*Alcippe peracensis*). *Schoeniparus* fulvettae are undergrowth-dwelling birds of primary forest, but extending through secondary and disturbed formations out into bamboo, scrub and old cultivation. The Dark-fronted Babbler (*Rhopocichla atriceps*) of south-west India and Sri Lanka, although geographically very restricted, nevertheless favours a wide range of habitats below 2100 m, including forest undergrowth, secondary growth, plantations, marshy thickets, scrub, reeds and bamboo. *Stachyridopsis* babblers are very similar to each other not only in appearance and structure, but also in elevational range and habitat, being found in undergrowth and up to the middle storey in open forest, thick secondary scrub jungle, bamboo, bramble (*Rubus*) and lantana (*Lantana*) thickets and overgrown cultivation. This means that, like the Chestnut-faced Babbler on the Philippine island of Luzon, the Golden Babbler (*Stachyridopsis chrysaea*) in Sumatra can penetrate upper montane primary vegetation, while on the latter island the Rufous-fronted Babbler (*Stachyridopsis rufifrons*), which may prove to be a slope specialist, has been suggested as having a particular association with bamboo. Glades, streamside vegetation, cut-over scrub and bamboo all feature in habitat descriptions of the *Pseudominla* species with the exception of the Black-crowned Fulvetta (*Pseudominla klossi*), which in fact occupies the same habitat as the Rufous-winged Fulvetta (*Pseudominla castaneiceps*).

The South African genus *Chaetops* contains two species, one of which is the **Cape Rockjumper**.

These forms have long been postulated to be babblers because of the loose, copious body plumage, particularly on the rump. This clue was misleading, however, as genetic analyses have recently shown a link with the picathartes (*Picathartidae*) of West Africa. It is now commonly thought that rockjumpers are sufficiently distinct in structure, breeding biology and rock-dwelling habits to warrant a separate family of their own, *Chaetopidae*.

[*Chaetops frenatus*,

The widespread Asian genus *Pomatorhinus* consists of classic forest-edge species, with a typical range of habitats from forest understorey out into bamboo, scrub, bramble thickets, overgrown clearings, abandoned cultivation and long grass. Only one species of the 14 in the genus appears to be stricter in its niche: the Coral-billed Scimitar-babbler, while using both bamboo and wild banana groves, and even though preferring light gaps, is limited, at least in Bhutan, to more continuous tracts of forest, shunning fragmented areas. In Bhutan, the Streak-breasted Scimitar-babbler (*Pomatorhinus ruficollis*) remains more inside forest at lower elevations, where it overlaps with the Rusty-cheeked Scimitar-babbler (*Pomatorhinus erythrogastrus*), but at higher elevations it emerges into scrub and open conifer forest. Most species in this genus have an elevational range of around 2000 m, starting at or near sea-level, but the Spot-breasted Scimitar-babbler (*Pomatorhinus maclellandi*) is restricted to a belt at 750–1830 m and the Indian (*Pomatorhinus horsfieldii*) to one at 915–2135 m, while the Streak-breasted Scimitar-babbler is found within altitudinal zones of varying widths in various places, the widest by far being in China, where it ranges from 200 m to as high as 3400 m. The Large Scimitar-babbler (*Pomatorhinus hypoleucos*) is generally a bird of lower-lying areas at up to 1500 m in the majority of its large range, but it is strictly montane in southernmost Thailand and Peninsular Malaysia, where it is found at 915–2135 m. The Chestnut-backed Scimitar-babbler (*Pomatorhinus montanus*) makes a similar shift between, on the one side, Peninsular Malaysia and Sumatra, where it occurs from sea-level to 1350 m, and, on the other, Java and Borneo, where its respective limits are 1400–2000 m and 500–2800 m. Already mentioned as a possible bamboo specialist, the closely related Sick-billed Scimitar-babbler, a species in its own genus, seems also, from its use of dense undergrowth and shrubbery in and near forest, to be classifiable as a forest-edge bird.

Certainly the tiny wren-babblers of the genera *Spelaornis*, *Elachura* and *Pnoepyga* are all inhabitants of forest edge, an inevitable condition of being adapted to foraging on the ground in dense low vegetation—small-stature birds for small-stature habitat. They are found in dense undergrowth on steep terrain, usually near running water and/or roads and tracks where naturally occurring breaks in the canopy are matched by broken ground with moss-covered boulders, rocks and fallen trees intermixed with luxuriant ferns, bracken (*Pteridium*), bamboo, often of dwarf type, and a rich herb layer often with *Strobilanthes* and nettles (Urticaceae). One species, the Tawny-breasted Wren-babbler

(*Spelaornis longicaudatus*), even penetrates treeless areas on hillsides. The 13 species contained in these three genera have elevational ranges that vary between 900 m and 1900 m in width, all except two of them starting at 1000 m or above. The exceptions are the Spotted Wren-babbler (*Elachura formosa*), the lowest breeding altitude of which is 300 m, and the Pygmy Wren-babbler (*Pnoepyga pusilla*), which, as the Chestnut-backed Scimitar-babbler, exhibits an upward shift through the Indonesian archipelago, breeding above 750 m in South-east Asia, above 900 m in Sumatra, from 1300 m on Java, from 900 m on Flores and above 1800 m on Timor.

Other small montane species that qualify as birds of forest edge are the attractive monospecific genera *Chrysominla*, *Mesia*, *Leiothrix*, *Siva* and *Myzornis*, although there are important differences between some of them. The Bar-throated Minla is mostly a canopy-dwelling bird when in forest, but it ranges down through open low-stature birch (*Betula*), willow and barberry (*Berberis*) woodland into bushy open country. The Silver-eared Mesia (*Mesia argentea*) is rather more confined to forest, although it does extend into heavily man-modified terrain such as abandoned tea and other plantations; in Bhutan, on the other hand, it appears to be a light-gap specialist in continuous forest, not occurring in extensive edge habitats. The Red-billed Leiothrix requires open forest with a berry-bearing shrub layer, forest edge, abandoned fields and bamboo. The Blue-winged Siva is very similar to the leiothrix in its needs, but it also occupies *Fokienia* forest in Indochina. Completing the list, the Fire-tailed Myzornis, a flower specialist, inhabits oak-rhododendron (*Quercus-Rhododendron*) forest, rhododendron and juniper (*Juniperus*) scrub, bushes and bamboo. Each has an elevational range covering at least 1500 m, the lowest, *Mesia*, typically starting at 600 m, and the highest, *Myzornis*, at 2000 m.

Three of the seven species of barwing clearly qualify as forest-edge species. These are the Rusty-fronted (*Actinodura egeroni*), Spectacled (*Actinodura ramsayi*) and Black-crowned Barwings (*Actinodura sodangorum*), the last only recently described. All three inhabit dense undergrowth, shrubbery, bamboo, tall grass and scrub in forest and secondary growth, and all three occur at rather lower elevations than do the four that are less obviously edge species. In Bhutan it has been observed that, in the belt where they overlap, the Hoary-throated Barwing occupies the canopy and the Rusty-fronted the bushes and undergrowth, but that, in places where one of the two is absent, the niches of the other species tend to expand more.

One behavioural trait found repeatedly throughout the family is that of group-living. Most babblers are at least seasonally gregarious, and many live in extended family groups all year round. The Grey-throated Babbler, for example, forages in parties of 5–20 individuals in the non-breeding season, often in association with other timaliids. These groups are generally furtive, but will emerge to scold an intruder with loud alarm calls, or when boisterous squabbling breaks out.

[*Stachyris nigriceps borneensis*, Mount Kinabalu National Park, Sabah, Borneo. Photo: Ong Kiem Sian]

Laughingthrushes are classic timaliids in their gregarious habits and group territoriality. They tend to forage in closely knit pairs or small parties, as is the case of the **Red-tailed Laughingthrush**. The soft, scalloped grey of the body plumage, and the rich ochre and maroon of the crown and tail, make it one of the most stunningly beautiful of babblers. This photograph, taken in captivity, captures these attractive features, but not the true character of the species. It is a shy South-east Asian bird, rarely emerging into the open, preferring to forage close to the ground, or amongst the leaf litter, in the shady understorey of montane evergreen forests.

[*Trochalopteron milnei*.  
Photo: Cyril Laubscher]

A slightly different phenomenon, also in Bhutan, has been noticed in respect of two species of *Garrulax* laughingthrush. In this case, there appears to be no habitat-partitioning but merely species replacement or numerical suppression, the White-throated Laughingthrush being supplanted at lower elevations by the White-crested Laughingthrush, with the effect that, in an area where the latter is absent, the former is common. This is interesting because, although both species commonly forage on the ground, the White-throated is as much a bird of the middle storey. Moreover, while the White-crested Laughingthrush certainly counts as a forest-edge species—something that one must assume also for the closely related but little-known Black-and-white Laughingthrush of Sumatra—the White-throated Laughingthrush is generally somewhat more an inhabitant of forest interior, falling in the habitat category of “forest and edge”.

Forest-edge laughingthrushes involve at least nine genera. At lower elevations, the White-crested, Greater Necklaced and Lesser Necklaced Laughingthrushes (*Garrulax monileger*) represent all *Garrulax* in this category, and these three species often co-occur from forest through to bamboo and scrub, and from sea-level to very roughly 1800 m. The five species to which these three are most closely related are, however, so far as can be judged, better treated as forest-interior birds with elevational ranges rather more straitened, since they begin in the foothills between 400 m and 800 m and all terminate at or below 1800 m: they are the Rufous-cheeked, Grey (*Garrulax maesi*), Black-hooded (*Garrulax milleti*), Cambodian (*Garrulax ferrarius*) and White-necked Laughingthrushes (*Garrulax strepitans*). In contrast, the six non-singing, non-laughing but highly sociable relatives in *Dryonastes* all occupy forest-edge habitats, albeit with broadly similar elevational ranges, none higher than 2000 m. These are the Rufous-vented (*Dryonastes gularis*), Wynaad, Blue-crowned (*Dryonastes courtoisi*), Yellow-throated (*Dryonastes galbanus*), White-cheeked (*Dryonastes vassali*) and Rufous-necked Laughingthrushes, all typically found in such places as forest undergrowth, bamboo jungle, secondary growth, scrub and the borders of cultivation, the last-named even spreading out into

tall grass and reeds, often along streams, brambles, hedgerows and tea gardens.

The four species in the two Sundaic genera *Rhinocichla* and *Melanocichla* show mixed evidence of being forest-edge birds, the former being the more obviously so. In Peninsular Malaysia and Sumatra, the Spectacled Laughingthrush (*Rhinocichla mitrata*) occupies forest, edge, low growth and overgrown fields from 900 m or lower up to 3200 m, and in Borneo the Chestnut-hooded Laughingthrush (*Rhinocichla treacheri*) exploits similar habitat in an even wider elevational range, from 200 m to as high as 3350 m. The Black Laughingthrush (*Melanocichla lugubris*), which shares its range with the Spectacled, and the Bare-headed Laughingthrush (*Melanocichla calva*), which shares its with the Chestnut-hooded, are more limited in elevation, with extremes of 500 m and 1800 m, and seemingly also in habitat width, utilizing the lower and middle storeys of forest, including secondary disturbed forest, the former, at least, occurring also in edges and at light gaps. Perhaps *Melanocichla* is a timaliid more of forest interior, as its dull coloration would seem to imply.

At broadly similar elevations to those used by *Melanocichla* are the closely related pair of *Stactocichla* laughingthrushes, both of which skulk deep inside understorey shrubbery, edges, light gaps and densely overgrown fields and borders, and the two closely related members of *Strophocincl*a in southern India, both of which occupy thickets, scrub and overgrown edges of plantations, and one of which, the Kerala Laughingthrush (*Strophocincl*a *fairbanki*), is thought to have its range circumscribed by that of the wild raspberry (*Rubus*). The remaining three *Strophocincl*a, all in the north of the Indian Subcontinent, have higher-lying ranges, two with upper limits at 2400 m and one at 3000 m, and occupy thick scrub, bushes and grass, as well as more obviously anthropogenic habitats such as field borders, gardens and other areas around human settlements.

Also to be found in patches around mountain villages are the Moustached Laughingthrush (*Lanthocincl*a *cineracea*), Rufous-chinned Laughingthrush (*Lanthocincl*a *rufogularis*) and Spotted Laughingthrush and the anomalous Striated Laughingthrush. The

first avoids primary forest, the second actively profits from shifting cultivation, and the third enters scrub bordering fields. The fourth is a bird of the middle storey and lower canopy in forest, but it also extends into scrub jungle, thickets and bamboo clumps, mainly at 1000–3000 m; in Bhutan, this upper limit coincides with the distribution of cool broadleaf forest. Vaguely similar in appearance to the Striated Laughingthrush, the three species of babax (*Babax*) range much higher, well above 4000 m, and are adapted to life on the ground and in the lower strata of montane and alpine vegetation such as stands of juniper, willow, sea-buckthorn (*Hippophae*) and prickly oak, scrub, brambles, bracken and grass. These birds, some of the largest of all babblers, must therefore find themselves sometimes in the fleeting company of some of the smallest in the family, as the White-browed (*Fulvetta vinipectus*), Ludlow's (*Fulvetta ludlowi*) and Grey-hooded Fulvetta (*Fulvetta cinereiceps*) all occupy bushes, scrub, juniper, dwarf willow, birch, stunted rhododendron, brambles and bamboo at upper elevational levels near the tree-line, as well as using taller forest.

This huge group of forest-edge species is completed by 14 members of the genus *Trochalopteron*, some of which rival the babaxes for the distinction of being the highest-elevation babblers in the world. The Brown-cheeked (*Trochalopteron henrici*), Elliot's, Variegated (*Trochalopteron variegatum*) and Black-faced Laughingthrushes (*Trochalopteron affine*) all reach over 4000 m, the last-named attaining 4600 m, the same as the Giant Babax, and at these upper limits all are tree-line species of upper forest edge, pushing into scrub and bushes in sheltered gulleys. None of the 14 species occurs normally below 900 m, and almost all of them are typically associated with forest and edge, bamboo thickets, shrubbery, scrub and clearings. The Red-tailed Laughingthrush (*Trochalopteron milnei*) presents an interesting example of a species which in one country, in this case Thailand, is known to utilize scrub but in an adjacent one, Laos, is instead a denizen of continuous hill evergreen forest.

The final two members of *Trochalopteron* separate into the final two habitat categories, those of "forest and edge" and "forest", although, as noted already, the distinctions are clearly weak and highly dependent on reports in the literature and their interpretation. One is the Scaly Laughingthrush (*Trochalopteron subunicolor*), which inhabits broadleaf forest, dwarf rhododendron and bamboo. The other is the newly discovered Golden-winged Laughingthrush (*Trochalopteron ngoclinhense*), which

has to date been recorded only in the understorey of relatively low-stature primary montane forest, an interesting circumstance, given that its close relatives in the Chestnut-crowned Laughingthrush (*Trochalopteron erythrocephalum*) complex all use forest-edge habitats.

"Forest and edge" species are defined as those which appear to be able to use either habitat, but which are not clearly identified as having a variety of non-forest habitats into which they might spill from taller adjacent edge cover. They are very considerably fewer in number. In addition to the two *Trochalopteron* mentioned above, this category contains the four remaining *Actinodura* barwings and the five remaining *Ianthocincla* laughingthrushes, at least two of which, the White-speckled (*Ianthocincla bieti*) and Giant Laughingthrushes, reach elevations above 4000 m but appear nonetheless to be confined within forest. All eleven yuhinas in the genera *Yuhina* and *Staphida* and the non-yuhina *Erpornis* occupy such habitat, in all cases involving broadleaf evergreen forest even at higher elevations, three species ascending above 3500 m, although some conifer stands are then also used. In a recent study of the Taiwan Yuhina, 83.5% of nests were within woodland, rather than in orchards or adjacent open habitats, but these nests were closer to the woodland edge than would be expected from chance placement. The Black-crowned (*Sterrhoptilus nigrocapitatus*) and Rusty-crowned Babblers (*Sterrhoptilus capitalis*) are two representatives of their genus that seem to be less "edge-restricted" than are the others, and elsewhere in the Philippines both species of *Micromacronus* appear, from what little is known about them, to be birds of the canopy and undergrowth of forest and forest edge, as do the two *Robsonius* and the single *Leonardina* species, forest-floor specialists for which edge habitats may often be vital. The Black-headed (*Malacias desgodinsi*) and White-eared Sibilas (*Malacias auricularis*), which occupy elevations between very roughly 1000 m and 3000 m, inhabit both evergreen forest and edge, and in Africa the monospecific *Phyllanthus* is similar, albeit extending out into savanna and occasionally visiting gardens, but always keeping to the darkest areas.

African timaliids that seem confined to forest and woodland are the Thrush-babbler, which skulks in dense vegetation along streams in forest, gallery forest, damp woodland and thickets, and the Black-capped Illadopsis (*Illadopsis cleaveri*), which lives in the understorey of primary and secondary forest, swamp-forest and sometimes coffee groves. Afrotropical species of "non-babbler"

**The Southern Pied Babbler** is a good example of a well-studied gregarious timaliid. It is usually found in groups of up to 15 birds, often including 6–10 adults and up to three immature birds. These gatherings collaborate to defend large territories of 35–50 ha in African acacia savanna. They breed co-operatively, with up to 12 helpers at the nest. In all seasons, Southern Pied Babblers commonly form foraging associations with other species, including Red-billed Buffalo-weavers (*Bubalornis niger*), Crimson-breasted Shrikes (*Laniarius atrococcineus*) and Fork-tailed Drongos (*Dicrurus adsimilis*).

[*Turdoides bicolor*, Etosha National Park, Namibia.  
Photo: Günter Ziesler]

(see Systematics) that are likewise forest-bound are the Grey-chested Kakamega, which is rather like the Thrush-babbler in its preference for shaded streamside areas, albeit at higher elevations, the Spot-throat, which favours luxuriant wet montane forest of regionally variable type and has been recorded in forest edge, and the Dapple-throat, which favours similar forest but with areas of open floor enclosed by dense herbs and shrubs. The Madagascar Groundhunter dwells in the forest undergrowth and understorey, foraging in the leaf litter and on moss-covered trees and rocks.

The species just mentioned are all birds of the forest floor, which explains why they are not greatly recorded in edge habitats. In Asia, the same considerations largely apply. Here, there are 35 species in twelve genera that occupy the floor and/or the lower understorey in extensive forest tracts, with eight species in four genera typically in the middle storey. Among the ground-dwellers is a group of apparently closely related species representing the entire genera *Kenopia* (one species), *Ptilochila* (three), *Turdinus* (four), *Napothera* (three) and *Rimator* (four), all of which typically forage among leaf litter, on rotten fallen timber, amid rocks and around trunk bases, often in the vicinity of streams and gulleys but not necessarily with an open or broken canopy. There is little or no solid evidence for more precise habitat preferences, but the Large Wren-babbler is said to favour areas of the undergrowth dense with rattan (Calameae), salak palm (*Salacca*), bamboo and gingers, and this may well be true of several of the other species. Some are lowland timaliids, found below 1000 m, but most are also montane and *Rimator* is predominantly montane.

Other species in this list, while using the forest floor for foraging, make use also of other strata. The two *Sphenocichla* "wedge-billed" babblers are relatively arboreal, and three members of *Dryonastes* and eight of *Garrulax* will commonly forage on the ground but also in the middle storey, but all appear to be forest birds with no evident preference for edge habitats. One of the three *Dryonastes* that form a distinct group of "soft-plumaged" species, the Grey-sided Laughingthrush, has been thought in Bhutan to prefer dense stunted broadleaf forest on steep slopes with some bamboo, and it may be that similar parameters govern the occurrence or abundance of the other two, the Chestnut-winged and Rusty Laughingthrushes; on the other hand, the Grey-sided Laughingthrush occurs at higher elevations than these others, so that its preferences in Bhutan may have no bearing on those of its close relations at lower elevations elsewhere. The five mainly

Indochinese forest *Garrulax*, namely the Rufous-cheeked, Grey, Black-hooded, Cambodian and White-necked Laughingthrushes, feed largely on the floor in submontane broadleaf evergreen forest, using the middle storey when moving between foraging sites; all occur at reasonably similar elevations, from an average of 600 m up to 1600 m. Three other forest-dwelling species of *Garrulax*, the Rufous-fronted, Ashy-headed and Sunda Laughingthrushes, are essentially similar, although the Ashy-headed is more lowland in distribution while the other two ascend above 2000 m, and all three may possibly forage arboreally more than terrestrially.

There are eight species of "forest" babbler that habitually use the middle storey. The five *Malacopteron* babblers, birds of extreme lowlands, do so, although two are treated above as forest-edge birds. So also do two closely related *Garrulax* of montane elevations, the White-throated Laughingthrush, already mentioned for its apparent interactions with the White-crested in Bhutan, and, on Taiwan, the Rufous-crowned Laughingthrush, although both of these commonly forage on the forest floor. The Red-tailed Minla (*Minla ignotincta*) seems to be more a bird of the forest interior and, indeed, less of a canopy-dweller than is the Bar-throated Minla. Finally, it remains very unclear what kind of bird the Malia is, but this species, too, appears to be an inhabitant of the middle storey within forest. Like the Javan babblers mentioned in the preceding paragraph, however, it is so little known that its ecological classification is as uncertain as its taxonomic position.

### General Habits

Babblers are for the most part highly sociable species, and many of their habits and activities are determined by this trait. In a very crude review of the evidence, and always accepting that some species are not strictly timaliids (see Systematics), around 64% of the 309 species in the current treatment live in groups outside the breeding season, 14% live in groups throughout the year, and 13% appear to live mainly in pairs although, for some of the time, in small family parties. The remaining 9% are not sufficiently well known for the category in which they belong to be determined with any degree of certainty.

The presumption behind the figure of 64% is that these are species, almost 200 of them, which do not live simply in family parties but in flocks, variable in size through the year, formed by

Allopreening is a form of behaviour found almost ubiquitously amongst the true babblers. It appears to be an innate and fundamental type of comfort behaviour, especially as solitary captive babblers of more than one species have been seen to solicit allopreening by wing-drooping, head-raising and erecting of the feathers on the head and neck.

It seems to be most prevalent in species which live permanently in pairs or groups, and perhaps serves to strengthen bonds between individuals. In gregarious species, such as the Chestnut-backed Scimitar-babbler, a pause in foraging often leads to bouts of group preening.

[*Pomatorhinus montanus*.  
Photo: Brian J. Coates]

One offshoot of group-living is known as "clumping". This behaviour is frequently observed in social species, including waxbills (Estrildidae), certain cuckoos (Cuculidae), and babblers, especially *Turdoides*. It arises during periods of rest, or at nocturnal roosts, often beginning with one individual sidling up to another on a perch. This leads to more individuals joining the clump, with increasing enthusiasm, until the whole group is huddled together. Clumping is regularly accompanied by allopreening-solicitation and reciprocal allopreening, as demonstrated by this group of Jungle Babbler.

[*Turdoides striata striata*, Keoladeo Ghana National Park, Bharatpur, India. Photo: Otto Pfister]

the amalgamation of families. For example, the numbers of individuals in flocks of Grey-cheeked Fulvetas in Taiwan reach a peak in August, presumably when all the families unite, and a second peak is evident in November, presumably when the autumn flocks, having declined through mortality, themselves unite as the weather becomes colder; the lowest numbers, again owing to mortality rather than to the splintering of groups, are predictably present just before the breeding season. These circumstances appear to be the result of ecological adaptations that permit foraging of a certain type, and which are conducive to the formation of well-co-ordinated foraging parties in which, allowing for deaths, membership is stable. It is also the case, however, that babbler flocks, at least arboreal ones, commonly join the mixed-species parties that are formed daily, and, indeed, babblers are frequent components of such parties throughout the family's range within Asia. Even ground-feeding babblers attract followers such as drongos and *Dinopium* woodpeckers.

Arboreal babblers such as the *Alcippe* fulvetas can be nimble and frenetic in their movements, sometimes exasperatingly so to the observer trying to identify or study them, the birds hopping rapidly along and between branches and flying between trees and parts of trees with direct, zipping flight. Some species, however, can be relatively sluggish and methodical, examples being *Cutia*, *Crocias*, *Actinodura* and *Pteruthius*. On and near the ground the movements of the smallest species can be just as quickfire, but babblers at these strata tend to be the bigger species and their actions for the most part slower and seemingly less volatile, albeit no less impressive. Rufous-chinned Laughingthrushes, for example, shift their short wings and long tail to one side or the other as they twist and sideslip through dense vegetation in a smooth movement reminiscent of the rodent-like progress of certain cuckoos (Cuculidae) amid thick branches.

On the ground, some species, such as the Wrenit and the Puff-throated Babbler (*Pellorneum ruficeps*), may either run or hop depending on the context, whereas the *Napothera* wren-babblers always hop and the two *Robsonius* species always walk. Ground-dwelling babblers often move cautiously, and for some, such as the "chatterers" in the genus *Turdoides*, this may be a permanent circumstance, but when foraging confidently their movements can be fleet. The Streaked Laughingthrush (*Strophocincla lineata*) creeps around in a foraging patch but scut-

tles rat-like to the next one, and larger laughingthrushes can move from point to point in great bounding hops, the head held forward, the body horizontal, and the tail swinging slightly from side to side to maintain balance.

The rather strong legs of babblers enable many of them to perform acrobatic movements among branches. This applies even to larger species. Their strong grip is such that a babbler can lean forwards so far on a perch, craning the head well below the body to peer at something of interest, that it seems as if it should have fallen off long before. The Bare-headed Laughingthrush may creep about sluggishly for much of the time, but it can hang upside-down like a giant tit and, in pursuit of falling insects, it can almost free-fall through creepers, using its feet to grasp occasionally at a perch as it does so.

The flight of babblers is generally characterized as weak or, at least, it is strong only over short distances. Small species flit from branch to branch, tree to tree or bush to bush with whirring flight on a direct path, sometimes zooming very intently and purposefully in flocks across clearings, and, in the case of yuhinas, often covering fairly large distances. There are, however, some exceptions to this general flight behaviour. The Wrenit has a weak, relatively slow flight in which the tail pumps slightly to maintain elevation, and it rarely goes farther than 30 m in any one flight, although it is good at avoiding mist-nets. Likewise, the Yellow-eyed Babbler has a feeble, jerky and undulating flight. The Bush Blackcap flies on a direct and undulating course, but sometimes, when moving between perches, it gracefully parachutes down on outstretched wings.

Larger species, as typified by the laughingthrushes, the scimitar-babblers and the *Turdoides* babblers, can be rather clumsy, laboured and jay-like, their short wings and long tail adapted for alternate short bursts of whirring flight and longer horizontal stiff-winged glides, the tail often spread wide, usually ending with an upward swoop to land in leafy cover or else pitching at the base of dense vegetation. Such flights are typically at low level, a few metres off the ground; in open savanna-type country, the trajectory is horizontal or slightly downwards between trees, the birds making up height for the next stage by moving up through the branches. Groups of *Turdoides* babblers usually fly across open areas in single file or loose succession, in a hierarchically led tour of the territory. Of 21 group flights by Yellow-billed Bab-

blers in which individuals could be identified, nine were led by the dominant male, four by the dominant female and six by a high-ranking adult male. It is by such flights, for example, that the birds arrive near water in order to bathe.

Unlike the great majority of passerines, which remain standing in water while they bathe, babblers have a distinctive habit of bathing by repeatedly hopping in and out of the water. While briefly in the water they dip and shake the head, whirring the wings rapidly, with the body feathers widely fluffed out. Then they hop out, continuing to shake the wings, before returning for a second or third dip. This is thought perhaps to be an adaptation to deeper water—captive individuals preferred the deeper of two troughs provided—or an anti-predator device, but, as it is so rare among the passerines, it is difficult to comprehend how these considerations could have evolved to apply just to one group. Perhaps the explanation is to be found in the birds' group-living behaviour or even in some property of the plumage. A pioneer student of babblers in captivity, C. J. O. Harrison, confirmed this behaviour for the Rufous-chinned Laughingthrush, noting how an individual would hop in very briefly but flutter its wings so furiously that it would raise a small fountain of water; but he discovered that a Red-billed Leiothrix would spend even less time in its quick dip, and raise a commensurately higher spray when doing so, such that he "could stand in the house and tell by the fountain of droplets that shot up from the bowl in the aviary away down the garden which species was now enjoying a bathe".

The Wrenit uses standing water, if available, to bathe in this fashion. As with other babblers, vigorous shaking and preening by the waterside follow. When standing water is unavailable, however, it uses the moisture left on shrubs by fog or rain, moving about in the leafy crown, brushing and bumping against the wet leaves until its plumage is damp, and then shaking and preening in the normal way. This behaviour appears not to have been reported for other babblers, but it is almost certain to be a widespread habit and, for some arboreal species, it may be the only means of bathing, and it presumably may take place at any time of day following rain. For timaliids that come to standing water, however, there seems to be a preference for bathing during mid-afternoon lulls or as a pre-roosting activity. As examples, the Black-capped Illadopsis comes to small forest streams in the afternoon, while small parties of Rufous-throated Fulvettas (*Schoeniparus rufogularis*) are often found bathing in secluded streams at dusk.

Although adapted to arid environments, *Turdoides* babblers greatly favour bathing when circumstances allow it, and will come every day to a site in order to do so. In central Kenya, two or more groups of Brown Babblers may share artificial water sources such as birdbaths and drinking troughs; an approaching group choruses in order to announce its arrival, causing the group already present to withdraw. Southern Pied Babblers can be such enthusiastic bathers in artificial or temporary pools after rain that their feathers sometimes become stained from suspended silt, and they sometimes become so waterlogged that they have real difficulty in flying up to a perch, instead running and clambering into the branches. Brown, Yellow-billed and Jungle Babblers all indulge in sun-bathing, and this is probably widespread in the genus. In captivity, Chestnut-collared Yuhinas (*Staphida torqueola*) also sun-bathe, and Wrentits have been seen to dust-bathe, but these types of maintenance and comfort behaviour are very poorly documented among the family.

When preening, almost all species of babbler use the direct method of head-scratching. In other words, and unlike most passerines, they raise the leg directly to the head in order to scratch, rather than lowering the wing and moving the leg over it from behind. K. E. L. Simmons recorded direct scratching by the genera *Pomatorhinus*, *Chamaea*, *Turdoides*, *Babax*, *Garrulax* (*sensu lato*), *Leiothrix*, *Siva* and *Heterophasia* (*sensu lato*), but he found that, inexplicably, the Stripe-throated Yuhina (*Yuhina gularis*) employed the indirect, over-wing method of scratching. The family also has a peculiarity in the way in which it oils its feathers. In contrast to other passerines, babblers seem rarely to oil the head by use of the foot, whereby oil is transferred from the bill to the foot and then to the head. Instead, they usually simply rub the bill with the foot in order to distribute oil along the length of the bill, and then simultaneously rub the bill and head on the extended wing and the wing against the head, all at lightning speed, alternating from wing to wing, and spreading the tail and thrusting it sideways to steady the wing by pressing against it.

Simmons also kept a record of the number of bird species for which anting had been observed. By 1963, the total for the timaliids was 26, including the genera *Pomatorhinus*, *Turdoides*, *Babax*, *Garrulax* (*sensu lato*), *Leiothrix*, *Mesia*, *Siva*, *Yuhina* and *Heterophasia*, the last probably referring, in fact, to *Malacias*. To this list can be added a recently published record of a Bold-striped Tit-babbler (*Macronus bornensis*) which was seen to take ants individually from a twig and wipe them down its wings.

The bathing behaviour of babblers is said to be distinctive and unusual.

Unlike most other passerines, which often stand for prolonged periods part-submerged in water, some babblers dip themselves only briefly to whirr their wings, sending a flurry of spray into the air, before hopping to a dry perch. They repeat this process several times, never spending more than a few seconds in the water.

It is not known what selective pressures have shaped this technique, nor whether it is adopted by the Bar-throated Minla.

Elegem]

Bathing often occurs in tandem with other forms of comfort behaviour. When babblers have drenched themselves with water, they usually retreat to a nearby perch to preen their plumage thoroughly. This activity is interspersed with head scratching, which is almost always direct in timaliids (under the wing, rather than behind and over it). The **Large Scimitar-babbler** is shown here perching on a tree root after bathing, ruffling its wings, and perhaps raising its foot to scratch its head. This species is widespread in evergreen forests from north India to Vietnam and Peninsular Malaysia. It spends much of its time in pairs or small groups foraging on the ground.

Apart from preening and scratching, babblers use at least two other behavioural techniques to maintain their condition: "anting"; and "sunning". The vigorous application of ants to feathers presumably distributes toxic defence chemicals, perhaps to discourage parasites. Direct sunshine has also been shown to reduce the parasite load, but it may have other important benefits in terms of maintaining plumage quality. There is nothing on record in the literature about sunning in babblers, but this photograph of a **Spotted Laughingthrush** suggests that they adopt similar postures to other passerines.

[*Ianthocincla ocellata*.  
Photo: Kenneth W. Fink]

Anting by babblers is of two main types. The large laughingthrushes seem to be specialized for anting on the ground among ant trails. In these cases, the bird seizes an ant and rapidly applies it just once to the extreme tip of one wing, contorting the tail as it does so; the ant is then rejected and another seized for the same purpose, without the laughingthrush shifting its position. The smaller babblers, however, seem to be specialized in anting on a low perch, exploiting ants taken either from the ground or from the foliage. They use each ant several times in a rapid series of applications, again to the underside of one wingtip at a time, with the tail thrust sideways. Reports that the birds are thrusting ants into the tail or the ventral area are the product of an optical illusion. Nevertheless, a Red-billed Leiothrix kept by L. Gibson not only made such movements, rubbing the ants on the outside primary feathers of a drooped wing, but also applied the ants violently to the body under an extended wing, at the same time adopting a stilt-like stance on extended legs, and afterwards in each case eating the insects.

A young female leiothrix kept by Gibson also performed anting movements with a shoot of *Actinidia*, as did a three-year-old female Silver-eared Mesia with a sprig of *Nasturtium*. In each case, the bird stood high, in an anting pose, and vigorously scrubbed itself with the plant for several spells each of 10–15 seconds. In both instances the sprig was sappy, but no clear explanation of this behaviour could be offered any more than for anting. A Rusty Babbler was once seen at dusk to carry a small dead snake near its preening group, then drop it and preen itself ecstatically over the body, attracting four Arrow-marked Babblers to watch from adjacent bushes. Whether the Rusty Babbler was using ants from the snake's body or deriving a more direct stimulus from the reptile's skin is unknown. It certainly seems, however, that anting and anting-like behaviour are relatively frequent and widespread among the babblers, and deserve more investigation.

Even so, ■ far more prevalent and important timaliid comfort behaviour is that of allopreening. Harrison suspected it to be practised by most, if not all, species, and he had records for *Garrulax* (*sensu lato*), which on current knowledge would have included also the species in *Dryonastes*, *Strophocincla*, *Stactocichla* and *Ianthocincla*, as well as for *Leiothrix*, *Mesia*, *Pomatorhinus*, *Chrysomma*, *Turdoides* and *Chamaea*. To these can now be added

*Zosterornis* and *Crocias*, and a careful gleaning of the avicultural literature would probably reveal many more. Harrison noted that all of the birds on his list have apparently long or permanent pair-bonds, and that the behaviour seems deeply ingrained. Even solitary captive individuals of the White-crested Laughingthrush and Yellow-eyed Babbler have been seen to pause during autopreening and then to adopt allopreening-solicitation postures, such as wing-drooping, head-raising and erecting of the feathers on the head and neck.

Allopreening by babblers cannot be dissociated from another notable behaviour, otherwise demonstrated most markedly by waxbills (*Estrildidae*), known as "clumping". Clumping describes the huddling behaviour exhibited by social babblers, particularly *Turdoides*, during periods of rest in the course of the day and at night-time roosts. It is sometimes initiated simply when one individual approaches another on a perch, landing some centimetres away, and then sidling up to it and pressing against it. Those joining a pre-existing clump, however, are less inhibited and alight directly next to the already clumped birds, and, indeed, the vigour with which babblers attempt to join a clump appears to be positively correlated with the number of individuals already in it. This clumping, even when only two birds are involved, is always accompanied by allopreening. Once clumped, first one individual and then the other preens its companion's head and neck. Special attention is given to the chin and throat, the receiving bird remaining stock-still, frequently with the bill held upright. Often, one babbler will preen the other hurriedly for a few seconds as if in encouragement, and then hold its own head up in position, inviting reciprocation.

In A. J. Gaston's classic study, allopreening by Jungle Babblers proved to be commoner in winter than in summer, possibly because of heightened aggression and competitiveness in the latter period, and also to be commoner in the afternoon lull when feeding was least intensive. Allopreening was otherwise common immediately following an event that induced an elevated state of excitement, such as a confrontation between groups, the giving of a predator alarm or disturbance by a human observer. Gaston suggested that allopreening invitations by ■ low-ranking member of the group are attempts to form coalitions with senior-ranking members in order for the former to promote its own status, by demonstrating to other group-members the degree of its

Many babblers are vocal birds, as indeed their name suggests. The extent of their repertoires is highly variable, as is the acoustic structure of their signals, but year-round singing is the norm. The song of the **Yellow-eyed Babbler** consists of loud whistled phrases, often given at fairly short intervals. The alarm calls are dry, harsh and churring. Individuals disturbed while foraging or nesting will often scold a predator with these calls from close quarters. This species is very widespread in an Asian range delimited by Pakistan, China, Sri Lanka and Vietnam. It avoids forest, preferring reedbeds, coarse grassland, swamps, and the margins of agriculture.

[*Chrysomma sinense sinense*,

acceptance by that senior member. This explains why most soliciting is directed at the most dominant individual and why clumping exerts a stimulus for others to clump.

A. Zahavi and A. Zahavi's even more classic study, forming the core of their major book *The Handicap Principle*, concludes that allopreening, in this case by Arabian Babblers, is a repeated test of the birds' social bonds with each other:

"The babbler being preened puts itself at the preener's beak, feathers fluffed and eyes often closed to let the other preen its facial feathers fully. The recipient of the preening can hardly see in that state and obviously is not prepared to fly or flee. The preener tests the other's will to cooperate with it, and the one being preened shows off that it trusts the other to warn it in case of danger. Both, by clumping and allopreening, take on a greater risk than birds resting alone."

Confrontations between neighbouring groups can be seriously risky events for an individual bird, and it is vitally important that it constantly reassures itself that, if full-scale fighting does take place, its groupmates will be no less committed. Power relationships within groups are always slightly, and occasionally dramatically, shifting as young birds mature, older ones die off, some individuals immigrate or are evicted, and each member constantly jostles for supremacy of some sort. Therefore, a group-member can constantly check and confirm the solidity of its status within the group and also the reliability of the other members' commitment to it by means of the many bouts of daily clumping and allopreening, which every few days are supplemented, at least among Arabian Babblers, by a remarkable group dance, performed at dawn in the open, in which the birds press against each other, squeezing under, over and between partners in a curious frenzy of activity. Perhaps unsurprisingly, the soliciting of allopreening is particularly frequent among juveniles and first-year individuals.

A less frequent but still common aspect of the behaviour of Arabian Babblers is allofeeding, but this varies with food availability and season. Experimental manipulation through food supplementation of a group and of individuals within the group, which has the effect of greatly increasing allofeeding rates, has elegantly shown that allofeeding is a dominance display. It is almost al-

ways the case that an individual of higher rank feeds one of lower rank, and never the reverse. The exceptions are situations when babblers of equally low rank engage in reciprocal allofeeding, and it is notable that receivers often refuse proffered food, thereby declining to signal their subordinate status to the giver. Even so, because dominance rankings are reasonably stable, allofeeding can be interpreted as displaying the prestige of the donors and the degree of dominance of one individual over another.

Social status also influences vigilance behaviour, for all the same reasons. Foraging groups are likely to be attractive to predators, especially if the foraging is being done in a herbaceous layer

The genus *Stachyris*, as currently constituted, seems to embrace three different vocal groups, each of which gives different song-types. The **Chestnut-winged Babbler** belongs to a group of three species with songs made up of mellow whooping or pooping notes, given in series. To produce these low-pitched notes it inflates its neck, baring two patches of skin. A similar effect is seen in passerines with comparable songs, such as the Neotropical *Hylopezus antipittas*. In the **Chestnut-winged Babbler**, the puffed-out neck-skin is a conspicuous pale blue or violet.

[*Stachyris erythroptera erythroptera*,  
Johor, Malaysia.  
Photo: Morten Strange]

Babblers are oscine passerines and are therefore thought to develop songs via an imprinting-like process.

Despite this fact, their songs generally lack some features found in many oscine families, including wide repertoires and mimicry. Vocal signals are a useful guide to higher-level taxonomic relationships in the Timaliidae, with the members of clear-cut genera tending to share distinctive song-types.

The **Rusty-breasted Wren-babbler**, for example, gives a series of loud, clear, mid-range whistles, typical of the genus *Turdinus*.

which may hinder the vision of the forager. Gaston found that, for at least 82% of the time when Jungle Babblers were observed, a sentinel was posted, for periods of less than four minutes in the morning but up to ten minutes in the afternoon. Change-overs were effected in three ways. In one, the sentinel flew down to feed and another bird then flew up to replace it. In the second, which was sometimes triggered by a call from the sentinel, a relieving bird flew up to join the sentinel and the latter then descended. In the third, the same thing happened as with the second method, except that the sentinel remained perched but diminished its vigilance and began autopsyching, before eventually descending to feed. Most sentinels were male in gender.

The Zahavi team has shown that no reciprocal altruism, no "fair sharing" of sentinel duties, is involved in this process and that, in reality, quite the opposite is happening. Despite the fact that the act of standing guard alone on a relatively exposed perch is itself a risky thing, and one that involves forgoing food for considerable periods as individual babblers may spend 2–3 hours per day on this task, the birds are actually competing among themselves for the chance to be sentinel. Careful study to record which birds stand guard and which replace them reveals that each individual makes the most effort to replace the one just below it in rank, so that, when it does so, it reconfirms its status in the group hierarchy. Some fascinating patterns in the group dynamics result. Frequent attempts to guard made by the second-ranking (*beta*) male are thwarted by the dominant (*alpha*) male, which keeps replacing him, but, because the *alpha* male cares far less about the threat posed to him by the third-ranking (*gamma*) male, the latter is able to do more guarding than is the *beta* male. When the *alpha* male dies, however, the *beta* male immediately takes over his role as the chief vigilante in the group, and turns the tables on the former *gamma* male, which is now the new *beta* male.

Once a threat has been spotted, the sentinel gives an appropriate warning. Recent study of sentinel behaviour among Arabian Babblers living in the path of a raptor migration flyway shows that the birds are sophisticated in their ability to discriminate between species posing a high predation risk and those representing lower threats, as well as in judging the degree of threat from the high-risk species, but generally always erring on the side of caution when uncertain of themselves. Moreover, they have slightly different-sounding calls for different predators, such

as raptors, snakes or cats, and this will doubtless be true of all the *Turdoides* babblers. The birds certainly learn quickly, as biologists who catch and ring them discover to their cost: the babblers immediately cease all habituated behaviour, they avoid the place of capture, and they growl in disapproval whenever the biologist appears. They rarely tolerate birds of prey such as kites and hawks (Accipitridae) and owls and owlets (Strigidae), or ground predators such as mongooses (Herpestidae) and snakes, near or in their territory or foraging area, and they mob them persistently. Furthermore, because of their numbers and their confidence in one another, they will sometimes launch fierce attacks on dangerous intruders. In one notable case, a group of five Southern Pied Babblers retaliated against a juvenile Gabar Goshawk (*Micronisus gabar*) that had caught one of its number, a nearly full-grown juvenile, attacking the hawk physically for ten minutes until it released the babbler and flew off; after only 15 m, however, the babblers caught up with the raptor, pinned it down and attacked it for a further five minutes, scrambling over it, constantly pecking at its head and neck, and leaving it to die of what proved to be a fractured neck joint, spinal-cord damage, puncture wounds and haemorrhages.

Food competitors, too, can feel the width of *Turdoides* displeasure. Southern Pied Babblers chase Cape Glossy Starlings (*Lamprolornis nitens*) from foraging areas, food supplies and daytime roosts, and displace doves (Columbidae), sparrows (Passeridae), weavers (Ploceidae) and shrikes. They even get into disputes with Arrow-marked Babblers in some areas. In one case, two groups, one of each species, approached each other, while emitting a cacophony of raucous calls, and seemed to form a loose circle. Each group then "delegated" one of its members, presumably a dominant individual, to take on the other species. Physical fighting, including much rolling on the ground and grabbing with the feet, ensued in the middle of the circle of onlookers, which raucously called as if in support of their champion. Southern Pied Babblers have been seen to defend daytime roosts and water resources from Arrow-marked Babblers, although the two species may forage in close proximity at other times.

Other babblers are rather more restrained, which is perhaps why there appear to be few examples of aggressive behaviour by them. The Brown Illadopsis, secretive, suspicious but inquisitive, will join other birds in mobbing snakes. Fulvetas in the genus *Alcippe*, despite their nervous-seeming disposition, flock

around an intruder demonstratively. There is probably a relationship between strength of reaction and the presence of an active nest or young, but food is clearly also a trigger, as illustrated by the Rufous Sibia (*Malacias capistratus*) and White-browed Shrike-babbler (*Pteruthius flaviscapis*), both of which can be very aggressive towards other species feeding in the same area as they. The Wrenit vigorously scolds nest predators such as the Western Scrub-jay (*Aphelocoma californica*), the bobcat (*Lynx rufus*), the grey fox (*Urocyon cinereoargenteus*), alligator lizards (*Elgaria*) and snakes, and potential brood parasites such as the Brown-headed Cowbird (*Molothrus ater*).

There are very few records of babblers being taken as prey, the best-known examples involving a laughingthrush caught in flight by a Black Kite (*Milvus migrans*) and an Arrow-marked Babbler found as prey of a Wahlberg's Eagle (*Aquila wahlbergi*). Nevertheless, the threat is ever present, and when a predator makes

an attack, rather than merely putting in an appearance, these and other smaller birds do, of course, take sharply to cover and are silent. As is discussed later (see Food and Feeding), drongo alarm calls, as well as strong alarms from sentinels in *Turdoides* groups, cause ground-feeding timaliids to fly up into cover. Caught unawares, they also simply freeze. Rufous-chinned Laughingthrushes do this when disturbed, and in so doing manage to "disappear" entirely; Harrison found himself repeatedly having to search the ground of his aviary if he entered it too quickly, for the birds' immobility and camouflage made it impossible to see them without real effort. The simple habit of skulking is, of course, its own kind of anti-predator behaviour. In Bhutan, the Rufous-necked Laughingthrush is a fairly common species, but it becomes so secretive in the later part of the breeding season that there are no July and August records of it in this country, and only a handful between the end of May and the start of November.

Night brings its own risks, and the roosting behaviour of babblers is a rich seam of unexplored questions for behavioural ecologists. Unfortunately, the evidence is very limited, for the most part restricted to a few anecdotes from the old literature, a few accounts of popular cagebird species, or the inevitable studies of *Turdoides* babblers. In all cases clumping occurs, even when only two birds are involved. Uniquely in the family, groups of Dark-fronted Babblers use an old nest for roosting. Yellow-eyed Babblers roost in groups of 20–30 individuals, but split up into smaller groups by day. White-throated Laughingthrushes do the opposite, foraging by day in flocks of up to 40 but roosting at night in subgroups of 2–6 individuals, each in a different tree. White-crested Laughingthrushes huddle so close together that they may cover each other with their wings. Captive Wrenitis sleep in groups of 2–5, their feathers fluffed and intricately overleafed, the individuals sometimes leaning against each other and using only the outer leg for support. Interestingly, pairs of Chestnut-collared Yuhinas roost on a twig, the two side by side but facing in opposite directions, each with the body inclined steeply forwards at 45°, as if poised to hop down from the perch. Two roosting Red-billed Leiothrixes can press themselves so tightly together on the roosting branch that they present the appearance of being a single bird with two heads and two tails, the ruffled body feathers forming a single fluffy ball which looks all the stranger when the birds tuck their heads down. So strong is this tendency that, in captivity, individuals of the same sex will readily roost in this manner and, if no other conspecific is present, lone individuals will attempt to clump with other babblers or even

The songs of *Turdoides* babblers are rarely noted for their beauty. These social birds do not produce melodious refrains, whistled notes or duets, but instead give raucous chattering cries. The harsh grating notes of the **Bare-cheeked Babbler**, for example, are often given communally in a deafening cacophony. These group vocalizations serve as a territorial or group-advertising signal, and as a rallying cry during territorial interactions.

[*Turdoides gymnogenys* kaokensis, Halali camp, Etosha National Park, Namibia. Photo: Geoff McIlhennion]

While some babblers vocalize as a group, others sing alone or as a pair. The male **Malayan Laughingthrush** usually sings with a clear and far-carrying "wip-weeeoo", the second syllable stressed; the female may accompany this with low mewing notes. The songs of babblers may provide an insight into the taxonomic status of geographically isolated forms, and in this case they reveal that the Malayan Laughingthrush is allied to, but probably not conspecific with, the Chestnut-crowned Laughingthrush (*T. erythrocephalus*), with which it was previously lumped.

[*Trochalopteron peninsulae*, Fraser's Hill, Malaysia. Photo: Jimmy Chew]

with unrelated passerines and non-passerines. Gibson noted that attempts by a single leiothrix to huddle with any sociable species were especially strong in cold weather, which seems to imply an underlying thermoregulatory value and poses some interesting biological questions about the physiology of this and other timaliids. Where clumping involves more than two individuals, however, a central position may have a further value, that of aiding predator avoidance.

In the case of *Turdoides* babblers, the roost-site is often quite low, 2–6 m from the ground inside the canopy of a tree or bush, although the Southern White-rumped Babbler may use reedbeds. One group of Jungle Babblers roosted in the same tree on eight successive days, while another varied between two trees, and it may well be that particular roost-sites are used over much longer periods of time, although not necessarily every night. In Gaston's study, roosts were usually at least 3 m up, on a branch 2–5 cm in diameter, with the innermost bird close to the junction with a larger branch. Usually, all birds faced in the same direction. Sometimes the babblers went straight to the roost-site, but on other occasions they visited "false roosts", up to 15 in number, before settling. Those entering roosts often clambered over the backs of earlier arrivals and tried to force themselves between already clumped birds. These struggles for position sometimes continued into darkness, but at other times everything passed off without any disorder. In cases where individual identities could be determined, dominant birds tended to enter the roost first, and non-breeding adults and second-years tended to be last. On some occasions, adults arriving at the roost late sat and waited for several minutes before joining the end of the roost line. The pattern, which seemed to be constant, was that the central birds were the breeding pair and one of the outer ones was a non-breeding adult male; in some cases, young juveniles entered the roost last but squeezed themselves into the centre of the group. Thus, over a period of several months, young juveniles perch first in the centre, then at 2–3 months of age move to the outer third, although not the extreme edge, and then move either to the outside or to the inner third as the next generation of juveniles arrives. Unsettled roosting behaviour may be related to issues of position within the roost line as age forces changes on it.

In India, it was once observed that members of a group of Common Babblers usually roosted such that some faced in one direction and others in the other, but that, when all faced the same way, towards the wind, this accurately predicted coming storms at night. "The babbler as barometer" was the headline. It seems, however, that in all other cases, whatever the species, roosting individuals all face in the same direction. One would conclude

that this intriguing anecdote perhaps suffered from a rather small sample size, possibly no more than a couple of cases.

## Voice

With such English names as "babbler" and "laughingthrush", it is hardly possible to think that vocalizations are unimportant for the Timaliidae. Of course, only a small proportion of babblers babble and few laughingthrushes laugh, but there is a wide variety of songs and calls in the family, as one would certainly expect from species which typically live well out of sight in thick cover or move about in large groups. A few species have immensely rich songs, some, indeed, being among the best-kept secrets of the avian world, whereas a few have no identifiable songs at all. Some songs are complex, and others simple. Some species duet, some sing as "trios", and others chorus, but most timaliids have pleasant whistlings and trillings, given by the male of a pair.

Duetting by babblers doubtless has a major function in pair-bond maintenance, but the phenomenon has not been analysed, and it is not clear how widespread it is. Even so, the evidence points to its extending across many taxa. For example, in this survey alone, duetting and antiphonal calling have been unambiguously recorded for 22 genera, representing roughly one-third of all babbler species: these genera are *Pomatorhinus*, *Sphenocichla*, *Macronus*, *Ptyrticus*, *Illadopsis*, *Pellorneum*, *Malacopteron*, *Malacocincla*, *Trichastoma*, *Turdinus*, *Napothera*, *Ptilocichla*, *Turdoides*, *Melanocichla*, *Sirophocincla*, *Ianthocincla*, *Trochalopteron*, *Liochla*, *Actinodura*, *Malia*, *Rhopophilus* and *Parophasma*. This list, however, does not take into account the information that comes from aviculturists, who have reported, for example, that in both *Mesia* and *Leiothrix* the sexes can be distinguished by call, the female having a short loud two-syllable whistle, to which its mate will respond with a quiet version of his song, or that the female Chinese Hwamei calls with a series of monotones, to which the male answers with a short burst of song. Evidently, these more informal aviary communications mirror circumstances unreported in the wild, and tend strongly to suggest that antiphonal calling between paired individuals may be a feature throughout the family, in some species and genera blooming into full song duets. It seems likely that all of this relates to the importance of the pair-bond among babblers, which is associated with the phenomenon of living in large groups.

Duetting, a common feature in babblers, has been unambiguously reported from 22 timaliid genera. This figure will doubtless increase when new information from field ornithologists and aviculturalists is compiled. To begin with, the monotypic genus *Kenopia* may belong on the list, judging by the evidence of this photograph. It appears to show a pair of **Striped Wren-babblers** vocalizing side by side in the manner of many duetting timaliids. Whether this species gives a true duet remains to be described.

[*Kenopia striata*,  
Johor, Malaysia.

Photo: Morten Strange]

Duets can be explained in terms of mate defence or joint territory defence, and it is sometimes difficult to disentangle these factors. Chorusing is more easily understood.

Three or more birds clump shoulder-to-shoulder vocalizing communally, as demonstrated by these **Red-tailed Laughingthrushes**. Such choruses show varying degrees of co-ordination: some are random, some highly syncopated, but all are thought to serve in group defence of a territorial resource.

[*Trochalopteron milnei*.  
Photo: Brian J. Coates]

Most babblers are essentially insectivores that supplement their diet with varying amounts of vegetable matter. Some are highly specialized; many are ecological generalists and opportunists. Their stout bills are designed for digging, prising and probing in a variety of substrates. The **White-browed Scimitar-babbler**, for example, forages anywhere between the ground and the lower canopy, using its decurved bill to pick items from leaf litter or tangled vegetation. In this case it has captured a large insect. This is a widespread, polytypic scimitar-babbler, occurring from India to Indochina.

Being mainly tropical, sedentary and either pair-territorial or group-territorial, babblers seem to sing all through the year. In Africa, the Brown Illadopsis, which J. P. Chapin noted as being the first bird species to call at dawn in the country then known as the "Belgian Congo", now DR Congo, sings all year, even at the height of the long dry season, in Gabon. Similarly, the chorus song of Sharpe's Babbler is heard all year, but with more complex chorusing over certain spans of months, presumably in relation to breeding activity. The Spiny Babbler of Nepal also sings in all months, but with greater frequency during the long period from March to September. The Wrenit does likewise, but with two peaks, the first from April to July, when breeding, and the second from late August into September, when expelling the young from the territory, and with the weakest output in November–December. With this species, as with birds of many different families, unmated males usually sing more frequently than do mated ones. One such was heard to deliver 450 songs in 90 minutes, a rate of five songs per minute, whereas in the more relaxed world of the mated male these songs, which are delivered in "bouts" of 3–6 at a time, are usually given at a rate of just 4–5 bouts per hour, an order of magnitude fewer.

The song of the Wrenit consists of five or six dry notes, all the same, that accelerate into a trill. This is not, in fact, unexpected from a bird which is judged to be relatively close to the *Sylvia* warblers (see Systematics), bearing in mind that several *Sylvia* species of xerophytic scrub have dry buzzing, rattling songs that somehow seem to match the dryness of their habitat. In stark contrast, the song of the African Hill-babbler (*Pseudoalcippe abyssinica*) is so strikingly beautiful that it has been considered by several ornithologists to be one of the finest in Africa. This species was described by H. Granvik as "the finest master-singer I have heard among African birds", and this, again, is not unexpected, given that *Pseudoalcippe* is also close to *Sylvia*, the parallel in this case being to the Blackcap (*Sylvia atricapilla*), a songster of celebrated richness in the lush, leafier clearings and glades in the woodlands that it inhabits. This latter is, indeed, the type of habitat used by both species of *Pseudoalcippe*.

The songs of the two *Pseudoalcippe* species are virtually identical, and it occasionally transpires that taxa that are strongly distinguishable in their morphology are poorly distinguishable in their vocalizations. For example, the Golden-crowned Babbler has a song very like that of its congener the Black-crowned Bab-

bler, while the Panay Striped Babbler sings like the Luzon Striped Babbler (*Zosterornis striatus*), and the Rufous-fronted Babbler sings like the Rufous-capped Babbler (*Stachyridopsis ruficeps*) and, indeed, like the Golden and Black-chinned Babblers (*Stachyridopsis pyrrhops*). Among the laughingthrushes, the Rufous-cheeked, Grey, Black-hooded, Cambodian and White-necked all sound the same, as do the Black and Bare-headed Laughingthrushes, and the Brown-cheeked has a song just like that of Elliot's Laughingthrush. Even among the "non-babblers" (see Systematics), the Chestnut-fronted (*Pteruthius aenobarbus*) and the Black-eared Shrike-babblers (*Pteruthius melanotis*) sound very similar.

Playback experiments designed to determine whether two taxa may be better considered species or subspecies do therefore, in the case of the Timaliidae, sometimes encounter problems. On the other hand, there are some species in which the song varies geographically, the Brown Illadopsis and the Spot-necked Babbler (*Stachyris striolata*) being two such examples, although the extent to which this carries any taxonomic information has not yet been explored. Moreover, the types of vocalization of certain genera and groups of babbler appear to be helpfully indicative of relatedness at levels above species rank. *Lioparus* and *Fulvetta* possess songs consisting of a few short high-pitched notes, and are clearly very closely related. The songs of *Yuhina* are not particularly well known, but some, at least, are sibilant and ringing, and consist of several to many notes. In contrast, the songs of *Staphida*, which until recently was regarded as a junior synonym of *Yuhina*, are the simplest imaginable, one or two notes in a series.

Across the South China Sea, the Philippine Islands host some intriguing species and no fewer than six endemic genera. The Flame-templed Babbler, for long included in the rather large South-east Asian genus *Stachyris*, has a song that helps to set it a long way apart; it sings a very pretty, descending, slurred jingle, reminiscent of, if anything, a speeded-up Silver-eared Mesia, and is now accorded a genus of its own, *Dasyerodapha*. The *Sterrhoptilus* babblers for which relevant information is available have simple, weak songs consisting of rapidly repeated single notes. *Zosterornis* babblers, in contrast, have high-pitched, rapid, jumbled songs that resemble those of white-eyes (*Zosterops*), inevitably triggering the fanciful notion that the accidental similarity of their scientific names may happen to indi-

cate a similarity in ancestry. As with *Dasycrotapha*, both of these timaliid genera were until recently merged with *Stachyris*, but both are clearly vocally distinct from it. Meanwhile, the song of the minuscule *Micromacronus* appears to be unknown, but those of the two remaining Philippine genera, *Leonardina* and *Robsonius*, are strikingly similar to each other, such that a relationship between the two appears very likely, despite the former often being considered a *Trichastoma* and the latter a *Napothera*. Both have an extremely high, insect-like whistling, quite unlike any sound yet recorded from any other species of babbler.

*Alcippe* babblers differ from those now treated in *Fulvetta* in the slightly more complex structure and flutier tones of their songs, but *Schoeniparus*, which also used to be subsumed in *Alcippe*, is vocally very similar to the latter. The song of *Rhopocichla*, the south Asian Dark-fronted Babbler, which has likewise been treated in *Alcippe*, has not been reported, and it is conceivable that this species does not have a true song. In contrast, the south Asian endemic Tawny-bellied Babbler, the sole member of the genus *Dumetia*, has a pleasant but piercing whistling song of descending notes. This connects with certain *Stachyris* babblers, but not others, although no record exists for the song of three of the twelve species. *Stachyris* songs are of three types, one involving pleasant simple high-pitched whistled phrases, as sung by the White-necked, Spot-necked and Grey-headed Babblers, another involving rolling quavering trills, as given by the Grey-throated, White-breasted and Crescent-chested Babblers (*Stachyris melanothorax*), and the third involving repeated mellow whooping and pooping sounds, as sung by the Black-throated, Chestnut-winged and Chestnut-rumped Babblers. The last four species named appear to have some kind of accompaniment from a presumed female mate, and the Chestnut-rumped Babbler has been reported as giving its whooping call in apparent trios or more.

There is a link in these latter calls, both in their "whooping" quality and in the emergence of a second singer, to the songs of the scimitar-babblers. The Sickie-billed Scimitar-babbler has a staccato hollow piping "wuwuwuwu...", and several of the *Pomatorhinus* species make similar sounds in duet, examples being the White-browed (*Pomatorhinus schisticeps*), Indian, Sri Lankan (*Pomatorhinus melanurus*), Chestnut-backed and Orange-billed Scimitar-babblers. The sounds produced by the second bird, presumed female, are often highly synchronized, so that the resultant impression is of a coherent "single" song. There are, however, degrees of co-ordination and structure in these songs that

may vary with season, as well as perhaps between species, and in some cases the duet is more obviously antiphonal, producing a "statement and answer" sound, rather than something so finely honed that a listener has difficulty in determining that two birds are involved. Indeed, the overall vocabulary of scimitar-babblers seems to be rather varied and not all songs involve duets, many being clearly the output of a single individual, but some being the combined efforts of three or more voices. This situation presumably mirrors their social lives, spent in pairs in the breeding season and in groups outside it.

Similar considerations may in due course apply to the genus *Sphenocichla*, for long thought to consist of one species but, following recent vocal evidence from P. I. Holt, alongside significant morphological differences, now treated as two species. These "wedge-billed" babblers possess surprisingly clear, well-structured songs but, again, duetting of some sort is frequently involved, although the birds live in fairly large groups outside the breeding season. The smaller *Spelaornis* wren-babblers are all rather similar in their song type, which involves loud, quickly repeated, rather mechanical series of jingling rolls and trills, but the Spotted Wren-babbler, which is normally treated as a member of *Spelaornis* (but see Systematics), has a very different, very high-pitched song which strongly suggests a link to *Pnoepyga* wren-babblers. These latter sing with high-pitched, simple series of notes, becoming more slurred and rambling in the song of the Scaly-breasted Wren-babbler (*Pnoepyga albiventer*).

The four *Stachyridopsis* babblers, the songs of which are, as mentioned above, almost inseparable to the human ear, give long rapid series of high-pitched monotone piping notes and are by this character well confirmed in their generic distinctiveness. This monotone piping may or may not provide a link to the *Macronus* babblers, the songs of which, like those of the scimitar-babblers and some *Stachyris*, commonly consist of rather low-pitched, hollow hooting notes, and which, as with *Pomatorhinus* and some others, may involve several birds, at least in the case of the Stripe-headed Tit-babbler. There appears, however, to be no call-and-response duetting in *Macronus*, whether highly co-ordinated or not; rather, the main singer produces a string of hooting notes, and this may or may not be accompanied by a second singer with a rather different, seemingly huskier and less organized series of calls. The distinctive Chestnut-capped Babbler has a husky metallic whinnying, sometimes involving more than one individual.

The **Silver-eared Mesia** is generally encountered foraging low-down at forest edges and in shrubby clearings, but it will ascend to the subcanopy of montane forests. It hunts for insects in foliage, occasionally making flycatching sallies after flushed prey, but never pursuing very far. It supplements this diet with small quantities of berries, fruits and seeds. Like many babblers, it often associates with mixed-species foraging flocks, even during the breeding season. Being so colourful, and having such a rich, melodious song, the Silver-eared Mesia is a popular cagebird in South-east Asia.

[*Mesia argenteauris tahanensis*, Fraser's Hill, Malaysia. Photo: Jimmy Chew]

**The Grey-headed Babbler** is one of several timalids that often forage among tangled vegetation and dead leaves. This species is usually encountered close to the ground, but sometimes ascends a few metres above ground where there are tangled creepers or hanging clusters of dead leaves. It usually targets small to medium-sized insects such as Orthoptera, and larval Coleoptera and Lepidoptera. The Grey-headed Babbler is a Sundaic species ranging in the lowlands to around 1000 m.

[*Stachyris poliocephala*, Khao Pra-Bang Khrum Wildlife Sanctuary, Krabi, Thailand. Photo: Kanit Khanikul]

The African genera *Ptyrticus* and *Illadopsis* both have songs in which two birds may participate. In the case of the first, the Thrush-babbler, this appears to happen only in one type of song, a series of disconnected notes like those of an Old World oriole (Oriolidae) that the presumed female instantly echoes. In *Illadopsis*, the extra participation is recorded for three of the seven species, the Pale-breasted (*Illadopsis rufipennis*), Brown and Mountain *Illadopsises* (*Illadopsis pyrrhoptera*), which happen also to be the ones in which the male is not reported as moving into higher strata of vegetation in order to sing. With these species, the additional sounds may be provided by one or two individuals, and consist of rather unco-ordinated conversational back-up chattering sounds. The main sound, from the presumed male, is a simple set of resonant melodious whistles, structurally and tonally quite distinct from the songs of Asian *Trichastoma* and *Malacocincla* babblers, in which genera the African taxa have in the past been treated.

Duetting is performed by the great array of mainly South-east Asian and Sundaic rainforest babblers associated with *Trichastoma* and *Malacocincla*, namely the genera *Pellorneum*, *Malacopteron*, *Turdinus* and *Napothera*, with *Ptilocichla* as a partial outlier. Songs of forest-dwelling *Pellorneum* are simple repeated two-note or three-note whistles, but these babblers also have slightly more complex, cheerful, skipping songs, sometimes dubbed "whistling schoolboy" or "errand-boy" tunes, which can trigger duet responses; the former song type appears to have a territorial function, while the latter may reinforce the pair-bond. *Malacopteron*, which does a fair amount of group calling, also has songs of two, and sometimes more, types. With the Sooty-capped Babbler it is the main song type, a slow string of up to nine rising-and-falling whistles, that often prompts back-up calling from the presumed female, while the secondary song type, as with *Pellorneum*, is the jauntier "errand-boy" version; whether this means that the functions of the songs are reversed is not known. The song of *Ophrydornis*, for long treated in *Malacopteron*, is not particularly different from songs of that genus but is more subdued and protracted, and duetting has not been documented. Similarly, of four *Malacocincla* and three *Trichastoma* for which the voice is known, no evidence of duetting has been found for two of the former, namely Horsfield's Babbler (*Malacocincla sepiaria*) and the Ashy-crowned Babbler (*Malacocincla cinereiceps*), and for one of the latter, the Ferru-

ginous Babbler (*Trichastoma bicolor*), but this may simply be an observational artefact. At present, the Short-tailed Babbler (*Malacocincla malaccensis*) is known to perform a highly co-ordinated duetting song, whereas "duets" of Abbott's Babbler (*Malacocincla abbotti*) involve the female contributing a few sharp notes in an unsynchronized manner, and only Abbott's is known to perform evening group calling. This may all change with greater study. The songs of these two genera are variable in quality but mainly rich, loud and flutey; those of the White-chested

**The Blue-winged Siva** is a group-living species, often found in parties of 5-20 individuals and at least sometimes breeding co-operatively. Groups of sivas spend much time foraging with mixed-species flocks of passerines in the canopy of montane forests, usually alongside other flock-following babblers such as minlas, cutias and sibilas. A variety of foraging techniques are employed by sivas in the hunt for insects and fruit. This individual is hanging acrobatically, apparently with the intention of snatching a poisonous-looking bug from the foliage.

[*Siva cyanouroptera sordidior*, Fraser's Hill, Malaysia. Photo: Morten Strange]

**The Short-tailed Babbler**

is not a flock follower. Singles or pairs forage low down or on the ground in the understorey of Sundaic forests. Here, they hunt for a variety of insects, including beetles, grasshoppers and ants. This individual is using its hook-tipped bill to extract a larval insect from a rolled leaf. In doing so it is demonstrating a distinctive feature of timaliid foraging behaviour: the use of the foot to grasp and clamp food items. This habit is generally uncommon in passerines, but shared with allied families such as the crows (*Corvidae*), the shrikes (*Laniidae*), the tits (*Paridae*) and the drongos (*Dicruridae*).

[*Malaccocincla malaccensis polioegenys*, Borneo.

Babbler are variable, with at least seven different permutations noted among all individuals heard at one site in Sumatra.

The Striped Wren-babbler, in the monospecific Sundaic genus *Kenopia*, produces a little inflected piping note, clear and monotone, and its presumed closest relative, the sympatric Bornean Ground-babbler, in *Ptilocichla*, makes a similar kind of song but, because it sings in sequential duet, it sounds as a double note, "doo-dee". The other two *Ptilocichla*, in the Philippines, are somewhat divergent, but the Streaked Ground-babbler (*Ptilo-*

*cichla mindanensis*) recalls *Trichastoma* with its two song types, while the Palawan Ground-babbler hints at its proximity to *Napothera* with mournful whistles. *Napothera* commonly embraces *Turdinus* and *Gypsophila*, but these are here separated for other reasons (see Systematics). *Gypsophila* is very different in its song, having a quick jumbled chattering which may or may not involve duetting. All four *Turdinus* species have simple mid-range whistles, loud and clear, delivered in series at different speeds, and sometimes with a second individual, presumed female, providing differently structured calls in duet, but the degree of stereotypy or co-ordination is unclear. The three *Napothera* species have simple clear piping whistles given at different speeds, at least two of the species sometimes duetting. The long-billed wren-babblers in the genus *Rimator* reveal their relationship to *Napothera* by singing with one brief repeated piping whistle, loud and piercing, but none of them is known to duet.

The highly sociable species in the genera *Gampsorhynchus*, *Pseudominla* and *Turdoides* have vocalizations which reflect their flocking habits. Thus, there is an absence of loud fluting and of clear piping, and relatively little, if any, duetting, since for much of the time the birds are all calling together as a group, whether in synchrony or not. *Gampsorhynchus* song has been reported as a rarely heard series of mellow low whistles, while the dominant sound is a loud harsh cackling chatter, given in groups. *Pseudominla* has a very high-pitched, very thin jumbled jingling trill for a song. With the exception of the Spiny Babbler, which has a rich, complex song giving further support to the notion that it may be better placed in its own genus (see Systematics), *Turdoides* have highly developed but relatively uniform, unmelodious vocabularies. Given that they live in groups all year around, this is perhaps unsurprising, but, even so, at least one species, the Striated Babbler, is known to perform duets.

Studies of the Jungle Babbler have discriminated eleven different vocalizations and identified both the caller within the group and the context in which they are given. (1) The "Shriek call", consisting of a short high shriek, is given by any individual at the unexpected appearance of a predator, causing the group to seek cover. (2) The "Weak Cackle call", a low intermittent wheezing, is uttered by sentinels to warn of potential but remote danger. (3) The "Strong Cackle call", a loud wheezy cackle, is given by one or more members of the group in the presence of a ground preda-

**The Puff-throated Babbler**

is a terrestrial forager, habitually rummaging among dead leaves and turning them over in search of insects. It occurs from India to Peninsular Malaysia and Vietnam, often in drier vegetation, including deciduous forests, roadside scrub, overgrown gardens, acacia thickets and bamboo. In these habitats, pairs or small groups make an audible rustling when searching for food. Some babblers hop when they are on the ground, others walk, but Puff-throated Babblers are known to use both modes of locomotion, depending on context.

[*Pellorneum ruficeps hilarum*,  
Kyobin, Myanmar.  
Photo: John & Jemi Holmes]

Many laughingthrushes are semi-terrestrial. Groups of **Greater Necklaced Laughingthrushes**, containing up to 25 individuals, band together with other *Garrulax*, including *White-crested* (*G. leucolophus*) and *Lesser Necklaced Laughingthrushes* (*G. monileger*). These unruly rabbles forage low down on a wide variety of fruits, taking them from low bushes or on the ground. They also dig for adult and larval insects, sometimes in fresh dung, as this photograph attests. Like so many babblers, this is a species of continental South-east Asia, where it is distributed widely from Nepal to China and Vietnam.

[*Garrulax pectoralis picticollis*, Hong Kong, China. Photo: John & Jemi Holmes]

tor or a perched raptor. (4) The "Group Cackle call", a loud wheezy cackle with a rising-and-falling guttural tone, is used by the entire group during confrontations with another group. (5) The "Chack call", a short "chack" uttered irregularly, is used for contact. (6) The "Cuk call", a short low intermittent "cuk", is occasionally given by a feeding individual. (7) The "Cu-cu-cu call", low and guttural, is an adult's announcement of its intention to move to a new site, and an enticement to others to follow; hence, it is used to encourage fledglings to fly. (8) The "Kya call", a loud ringing "kya-kya-kya", is an alarm summons given by a babbler when in distress. (9) The "Gurgle call", a low gurgling noise, with the wings loosely waving, announces a male's intention to copulate. (10) The "Scheer call", a low "scheer", signals submissiveness, as when a female approaches a male of another group or when one individual is dominated by another during "play". (11) The "Begging call", a rattling squawk, given by juveniles up to six months of age, intimates hunger.

Similar breadths of vocabulary are found for most other *Turdoides* that have been investigated, often, but by no means always, with contextually homologous calls. Some species, all Afrotropical ones, have petulant raucous, chattering chorus songs that act to rally group-members and advertise the group, particularly when confronting another group. That of the Scaly Babbler has the distinction of being thought one of the most grating sounds made by any passerine bird. Curiously, the only other babblers to produce a chorus song are the Capuchin Babbler (*Phyllanthus atripennis*) and the *Kupeornis* babblers of West and Central Africa.

Ongoing research is turning up interesting new evidence about the sophistication of signalling by *Turdoides* babblers. For example, different intensities and intonations of warning calls by Arabian Babblers provide remarkably precise information on the nature of the perceived threat. Further, Southern Pied Babblers have recently been shown to modify their ground-foraging contact calls as "recruitment calling", which summons nutritionally independent but inexperienced young to particular patches of food.

The Himalayan *Cutia* (*Cutia nipalensis*) sings in strings of the same loud, hard, high single note, up to 20 at a time though usually fewer. Its very close relative the Vietnamese *Cutia* (*Cutia feadleri*) has several song types, again involving strings of notes but either double ones or variable single ones. These calls, or songs, are by no means dissimilar in structure to those of the two crocias and the *Pteruthius* shrike-babblers, all of which also dwell in the

forest canopy. As with the morphological similarities of the species, however, the vocal likeness of *Cutia* to *Pteruthius* must be the result of convergence since, as already noted (see Systematics), these two genera are completely separate genetically.

The *Dryonastes* laughingthrushes fall into three subgroups which, if their vocalizations provide any guide to taxonomic relationships, present some interesting problems. The first group consists of the three beautiful rusty-and-grey species headed by the Grey-sided Laughingthrush, the song of which is loud and melodious but not yet sufficiently well known to be clearly characterized. The second group, consisting of the Black-throated Laughingthrush (*Dryonastes chinensis*) and Chestnut-backed Laughingthrush (*Dryonastes nuchalis*), delivers extremely rich, fluty and slurred songs, the birds living in pairs and being extremely territorial. The third group is made up by the six species led by the Rufous-vented Laughingthrush, all of which live in large groups and sing rather poorly, their main vocalizations being hard, shrill, scratchy twitters and rattles.

The genus *Garrulax*, ironically, does not entirely conform vocally, although all members live in fairly large groups. The seven species led by the Rufous-cheeked Laughingthrush live in large flocks in the same way as does the third *Dryonastes* subgroup, but their main vocalizations are "laughing goblin" calls, which are best known for the White-crested Laughingthrush, and from which this entire group of timaliids has acquired its English name. Greater Necklaced and Lesser Necklaced Laughingthrushes emit a much weaker laugh, and much less frequently. The Masked Laughingthrush sounds most like the White-browed Laughingthrush, a *Pterorhinus* species; both are inhabitants of open country. The remaining five *Garrulax* species, led by the White-throated Laughingthrush, deliver odd wheezy hissing or harsh squeaky snuffling guffaws. Whether these variations within the genus reflect different phylogenetic pathways or adaptations to particular types of environment remains to be clarified. It is to be observed, at any rate, that the *Melanocichla* laughingthrushes make loud hollow whooping sounds that are heard also, albeit with different qualities, from other, distantly related babblers of the lower storeys of rainforest—*Stachyris*, *Macronus* and *Pomatorhinus*—and, as these genera, they duet or even sing in trios. *Rhinocichla*, which occupies the same geographical range as *Melanocichla*, is a genus of more open forest habitats and its two members have more complex and structured strings of notes, given at a higher pitch.

Most babblers consume insects and fruit, with fruit making up the smaller proportion. Some species of high altitudes or temperate latitudes survive cold periods by switching seasonally to frugivory, while others forage on fruit when the opportunity arises. The **Brown Fulvetta**, for example, generally gleans insects, including beetles, caterpillars and grasshoppers, but will pause to eat small berries at any time of year. It is restricted to lowland evergreen forests from southern Thailand and Peninsular Malaysia to the neighbouring islands of Sumatra and Borneo, a region with minor seasonal fluctuations in climate.

[*Alcippe brunneicauda*,  
Panti Forest Reserve,  
Malaysia.

Photo: Ong Kiem Sian]

Among the brown laughingthrushes with camouflage streaks and spots there is great variation in song types. The babaxes give series of simple pleasant whistles with a thrush-like quality. The anomalous *Grammatoptila* has an outstanding rich burry song, one of the typical sounds of middle-elevation Himalayan forests. The two *Stactocichla*, inveterate skulkers in the densest of thickets and therefore, inevitably perhaps, birds that live in pairs, not in parties, have sensationally rich, mellow, complex and melodious songs, often involving mimicry; tape playback induces a state of vocal warfare. These songs are considerably richer than those of the two hwameis in *Leucodioptron*, which are so well known and loved for their song, a rich warble, faster and more slurred than that of *Stactocichla* but also often involving mimicry. This is true, at least, of the Chinese Hwamei, the song of which is considerably more intricate than is that of the Taiwan Hwamei, with the unfortunate outcome that Chinese Hwameis have been imported into Taiwan in high volume and many have escaped, leading to the danger of genetic and phenotypic swamping of the island endemic. The five *Strophocincla* have several song types each, generally including a short one, loud and clear, and a longer one, more complex and trilling. In the case of the Striped Laughingthrush (*Strophocincla virgata*), two types can be sung antiphonally, possibly one by the male and the other by the female, and this is true also of the Streaked Laughingthrush. The situation with the three other species in this genus is less clear, but duetting is performed by all of them.

The two rather featureless laughingthrushes of the genus *Pterorhinus*, birds of very open scrub and brushwood habitats, have shrill, simple vocalizations, although the least distinctive, the Plain Laughingthrush, compensates by having the most developed song, a rather sweet warble. Songs of the considerably more patterned *Ianthocincla* laughingthrushes, which live in deeper forest cover, are loud, clear and rather thrush-like, with rich, fluty, mellow notes; in the case of the Barred Laughingthrush (*Ianthocincla lunulata*) and the Spotted Laughingthrush, at least, some form of duetting takes place, the presumed female contributing quavering churring notes. The large genus *Trochalopteron*, with 16 species, possesses rather uniform songs, despite the great variety of plumages present. All of these consist of repeated short phrases of two or three loud, clear, rather thin, high whistles, often slurring up or down, liquid and musical, and in many cases with some sort of antiphonal calling from presumed females.

The five species of *liocichla* are fairly similar in their songs. The two "red-faced" species have rather loud, clear, jolly phrases and sound most melodious, the newly discovered Bugun *Liocichla* (*Liocichla bugunorum*) giving a fluty song of similar length, the Grey-cheeked *Liocichla* (*Liocichla omeiensis*) a weaker and shriller one with rather long slurred phrases, and the Taiwan *Liocichla* a quick high, short, cheerful phrase. Females of the Bugun and Taiwan *Liocichlas* often punctuate the male's song with three or four short buzzy churrs; whether this happens or is usual with the other species is not known. Recent study of Taiwan *Liocichlas* reveals that male song in duets is highly individualistic and varies significantly across different habitat types, with females more likely to duet with males in densely vegetated, steep forest habitat than in more open agricultural areas, suggesting that in this species, at least, females are duetting in order to reveal their location to their mates.

In the current taxonomic treatment and sequence, the tail end of the family consists of a number of species in their own genera, some of them clearly related to each other, some of them less obviously so, and with a concluding suite of "non-timaliid" forms (see Systematics). *Chrysominla*, *Minla* and *Siva* produce sweet, clear, high, hurried whistles, simple and *Fulvetta*-like; interestingly, *Leioptila*, while evidently a sibia, is vocally somewhat like a minla. Rather unpredictably for such colourful creatures, *Mesia* has a cheerful, loud, clearly spaced, descending short warble, and *Leiothrix*, known popularly as the "Chinese Nightingale", takes this a stage further into a longer, more complex fluty warble, rich and variable in structure, recalling, as does the song of *Pseudoalcippe*, the supposedly unrelated Blackcap of the warbler genus *Sylvia*. More predictable in terms of song is that a skulking African forest-undergrowth babbler such as *Phyllanthus* should have a pure musical whistle, although, as noted earlier, it also has raucous chorus songs of some vehemence; its relatives in the African treetops, the three *Kupeornis*, share the choruses but appear to lack any other type of song. In the treetops of Asia, however, *Crocias* has a rapid string of single notes or inflected notes for a song.

The nectar-eating sibilas fall into three genera and three vocal types. The Long-tailed Sibia in the monospecific *Heterophasia* has a simple series of notes that may serve as song, but the species is best recognized by the weird, wispy, high-pitched sounds, thin and metallic, produced by flocks. In contrast, the six *Malacias*

The genus *Turdoides* is largely made up of generalists. The *Fulvous Babbler*, for example, eats a mixture of insects, seeds, and berries. In its North African range it consumes a large quantity of invertebrates, including caterpillars, termites, beetles and grasshoppers. This diet is supplemented with fruit, chiefly *Ziziphus* and *Salvadora* berries, but also the fruit of the introduced prickly pear (*Opuntia*), pictured here. This babbler is familiar at desert camps and settlements where it will take scraps of bread and meat. It is relatively slender and quiet for a *Turdoides*, belonging to a subgenus sometimes referred to as the "chatterers".

[*Turdoides fulva maroccana*, near Goulmine, Morocco. Photo: Arnaud B. van den Berg]

sibias produce loud, well-structured songs consisting of high-pitched whistles, silvery and wavering, strident or resonant, but commonly descending in pitch at the end. As mentioned in the previous paragraph, the monospecific *Leioptila* is rather minlike vocally, but its attractive simple warbling also descends in pitch. The barwings, the genus *Actinodura*, sing in a manner that is fairly constant among the seven species, in short, clear, loud piping phrases, strident or wavering and often rather mournful. Oddly, only the Spectacled Barwing and the most recently described member of the genus, the Black-crowned Barwing, appear to have been documented as duetting, but presumably all do so to some degree. *Pteruthius* shrike-babblers string together single notes in monotonous, unmusical songs.

With the exception of the rockjumpers, all of the following species belong in monospecific genera. The White-bellied Erpornis has a curious high descending whinny, while the Fire-tailed Myzornis appears to have no song at all, individuals in groups making very thin, high, single sounds which, run together, produce a titting effect. True to its big size and chunky appearance, the *Malia* gives a raucous mix of guttural warbling and harsh grating sounds, but with one bird doing the warbling and the other the grating, and there is also a penetrating chorus call, which tends to suggest that the species may, indeed, belong in the timaliid assemblage (see Systematics). The same may be true of *Rhopophilus*, the Chinese Bush-dweller, which has a simple repeated inflected note as one song, and rich duetted calls presumably as another. The Juniper Babbler, *Parophasma*, reinforces its claim to be a babbler by virtue of the female's low churring support for the male's rich warbling trill. *Lioptilus*, the Bush Blackcap, has a loud lively jumbled song with bulbul-like phrases. From the depths of cover, the Grey-chested Kakamega gives fluty, melodious sets of phrases, warbling and liquid, the Spot-throat, *Modulatrix*, delivers loud, shrill, slurred whistlings, and the Dapple-throat, *Arcanator*, announces itself with quick, short, clear, pure melodies. The Rockrunner, *Achaetops*, sings rich clear bubbling warbling phrases from open songposts. In similar open positions, the two rockjumpers, combined in the genus *Chaetops*, utter long series of penetrating piping notes. The Principe Flycatcher-babbler, the sole member of *Horizorhinus*, gives loud

rich cheerful whistles, often in chorus, which tends to support the notion that it is a true babbler. Finally, the song of the Madagascar Groundhunter, *Mystacornis*, has a three-part structure, with two quiet high notes, a protracted mournful whistle and a harsh churr, quite unlike any "true" timaliid vocalization.

Mimicry appears to be poorly developed among babblers. The Spot-throated Babbler is described as singing "mimicked" phrases, with no further clarification, and Chestnut-winged, Chestnut-backed and Chestnut-eared Laughingthrushes (*Lanthocincla konkakinhensis*) are said to imitate other birds on occasion. The best mimics, it appears, are, in descending order of skill and/or frequency of imitation, the Spiny Babbler, which has songs very rich in mimicry, the Spot-breasted Laughingthrush and the Chinese Hwamei, three species that appear to be highly territorial and aggressive. Apart from these, the "non-timaliid" Rockrunner is reported as sometimes incorporating mimicry of other birds in its songs.

### Food and Feeding

Babblers are adapted to a broad invertebrate diet that is augmented, sometimes importantly, by vegetable matter. They are specialized for foraging on substrates in which immobile or slow-moving and often hidden invertebrates are couched. The stout bill of most timaliids is adapted to dig at, probe into and prise open surfaces in which food items may be present, including dry stems of grass, nodes of leaves, twigs and branches, curled dead leaves, old bark, rotten standing and fallen wood, epiphytic layers on tree surfaces, leaf litter and soft soil; it is used also for plucking fruits and nuts and for hammering prey items. The feet need to be fairly strong in order to support the birds in various acrobatic positions while they are foraging, and, at least in some species, including *Turdoides* babblers, laughingthrushes, the Red-billed Leiothrix and the Blue-winged Siva, to grasp and clamp food items, including nuts and hard-skinned fruit, for further processing by the bill.

As a very general rule, babblers could be said to be adapted to foraging on more aseasonal, or seasonally stable, substrates

such as dead leaves, sclerotic stems, woody vines, bark, branches, twigs, epiphytes, bases of herb clumps, fallen timber and leaf litter, but there are, of course, plenty of exceptions. All types of invertebrate are taken, with no apparent preferences, and captive laughingthrushes were ready to eat foul-smelling beetles (Coleoptera) and, once de-stinged, bees and wasps (Hymenoptera). In addition, small vertebrates are occasionally attacked, hacked up and consumed by the larger members of the family. Further, a bird as remote from human settlements as the Taiwan *Liocichla* will readily take food scraps thrown by birdwatchers from their lunchboxes, and one has been seen to eat the corpse of a conspecific.

Considering genera in terms of guilds, many babblers do, in fact, glean items from green leaves, whether in the canopy or in the shrub layer, but these birds glean also from twigs and branches, and they may be categorized as arboreal leaf-gleaners and twig-gleaners. They include the genera *Pseudoalcippe*, *Fulvetta*, *Yuhina*, *Sterrhoptilus*, *Zosterornis*, *Alcippe*, *Stachyris*, *Micromacronus*, *Macronus*, *Malacopteron*, *Ophrydornis*, *Trichastoma*, *Gampsorhynchus*, *Pseudominla*, *Rhinocichla*, *Chrysominla*, *Mesia*, *Leiothrix*, *Crocias*, *Siva*, *Pteruthius*, *Erpornis*, *Lioptilus* and *Horizorhinus*. Of these, however, *Sterrhoptilus*, *Zosterornis*, *Stachyris* and *Macronus* perhaps spend as much or more time on foraging in dead leaf tangles, *Yuhina* species also suck sugar-rich sap early in the year, *Yuhina* and *Pseudominla* glean moss-covered trunks, *Stachyris* babblers work on tree bark, and the *Gampsorhynchus* species glean bamboo-canopy leaves. Stronger specialism on dead leaf tangles is apparently displayed by the Flame-templed Babbler, *Dasyrotapha*, and all *Macronus* except the Fluffy-backed Tit-babbler, as well as by two *Stachyris* species, namely the Grey-throated Babbler and Crescent-chested Babbler. Altogether, these species account for 28% of the total in the family as presently constituted.

Several more specialized arboreal guilds exist. Babblers adapted for probing tree flowers for nectar and insects but which also probe mossy twigs and glean foliage include those in the genera *Heterophasia*, *Malacias* and *Myzornis*. Those that glean from epiphyte-bearing substrates under the canopy include species in *Staphida*, *Cutia*, *Minla*, *Kupeornis*, *Leioptila* and *Actinodura*. Specialist trunk and branch bark-gleaners appear to be

*Sphenocichla*, *Melanocichla*, *Malia* and three or four *Pomatorhinus* scimitar-babblers. Species that forage mainly or exclusively in the forest undergrowth, gleaning from leaves, stems and woody plant parts near ground level, are *Spelaornis*, *Elachura*, *Stachyridopsis* and *Timalia*. These combined account for around 16% of the family's members.

Terrestrial insectivores, here including species which may also forage in the low undergrowth 1–2 m above the forest floor, but excluding those that sometimes forage in higher strata in more open country, constitute a very large guild among the babblers. Genera represented in this include *Schoeniparus*, *Rhopocichla*, *Dumetia*, *Xiphirhynchus*, *Pomatorhinus*, *Pnoepyga*, *Ptyrticus*, *Illadopsis* (which also glean branches and trunks of trees), *Pellorneum*, *Malacocichla*, *Leonardina*, *Robsonius*, *Kenopia*, *Ptilocichla*, *Turdinus*, *Gypsophila*, *Napothera*, *Rimator*, *Stactocichla*, *Leucodiotron*, *Sterrhocichla*, *Pterorhinus*, *Ianthocichla*, *Trochalopteron*, *Liocichla*, *Kakamega*, *Modulatrix* and *Arcanator*. Species in *Illadopsis* also glean branches and trunks of trees. Some 34% of the family are represented in this guild.

Several genera of large babbler are sufficiently generalist to be considered in their own guild, one which combines arboreal leaf-gleaning and twig-gleaning with terrestrial foraging, the "arboreal and terrestrial omnivores". These are *Turdoides*, *Dryonastes*, *Garrulax*, some of which are more terrestrial than others, *Babax*, *Phyllanthus* and possibly *Melanocichla*, although the last-mentioned is included above as a specialist bark-gleaner. These constitute 19% of the family's members, leaving the final 3% to a few anomalous species. These last few comprise the three "non-babbler" genera (see Systematics) *Achaetops*, *Chaetops* and *Mystacornis* that feed exclusively on the ground, something that no "true" babbler appears to do, two open-country monospecific genera which glean mainly from the woody parts of plants, namely *Chamaea* and *Rhopophilus*, and the acrobatic grass-stripping *Chrysomma* and *Moupinia*. *Rhopophilus*, however, feeds also on the ground.

Berries, fruits and seeds are probably exploited mainly opportunistically and seasonally, but certainly more than as mere supplements, and in some cases they are major year-round components of the diet, as is so for certain *Turdoides* babblers in the Indian Subcontinent. The family's foraging specialization on sea-

Although its plumage is drab, the **Arabian Babbler** is a confident and colourful character. It has been the subject of long-term field studies and therefore its diet is relatively well known. It hunts for a wide variety of insects (crickets, beetles, caterpillars, wasps, etc.), invertebrates (spiders, scorpions, centipedes, etc.), and vertebrates; the last include lizards, geckos, snakes, and perhaps small mammals. It also eats nectar, petals, leaves, fruit and seeds, sometimes visiting cultivated crops. This individual has taken a liking to a cob of maize.

[*Turdoides squamiceps*  
*muscatensis*,  
Sohar, Oman.

Eriksen]

The sibilas show varying degrees of nectarivory. They use strong legs to reach nectar-bearing flowers, usually in a wide variety of canopy trees, including *Bombax* and *Erythrina*. They also visit flowering shrubs in clearings. This **Long-tailed Sibia** is visiting gardens to glean nectar from the flowers of an introduced Australian bush, the bottlebrush (*Callistemon citrinus*). Parties of this sibia are more typically encountered in the canopy of montane forest, where they associate with large mixed-species flocks, and eat a variety of insects, flower buds, fruits, berries and seeds.

sonally stable substrates predicates its adaptation to seasonally stable conditions more generally, and hence to year-round occupation of areas and habitats. Frugivory, by providing a key component of the diet in colder or drier periods when invertebrate abundance dips, further aids the decoupling of babblers from the need or ability to migrate other than in the form of vertical movements, which can be undertaken slowly and in piecemeal fashion. A self-reinforcing circle of adaptation comes into play: birds lose the need to fly great distances to forage, so they are compelled to diversify and specialize *in situ*, resulting in many cases in weak dispersive abilities, including shortened wings, which not only inhibit the colonization of seasonally favourable habitats but also encourage the development of group-living and cooperative breeding (see Breeding).

Of course, in some equatorial regions where seasonal variation is minimal, there are species that are, so far as is known, entirely insectivorous. *Malacocincla* and *Trichastoma*, for example, are genera for which no evidence of vegetable matter in the diet has been reported. On the other hand, a small number of species go to the opposite extreme. One, the Juniper Babbler of Ethiopia, appears to have been recorded as eating only fruit, mainly juniper berries, although it doubtless takes also insects at times, perhaps especially when feeding young. Another, the Spotted Laughingthrush, is reported as being almost entirely vegetarian except when feeding young, but, again, this possibility requires closer study. Several other higher-elevation *Lanthocincla* and *Trochalopteron* laughingthrushes probably have high proportions of fruits and nuts in the diet, since they live in places where annual temperatures and conditions fluctuate the most.

A study by Simmons of one species, the Rufous-chinned Laughingthrush, in captivity showed, however, that even within the realm of frugivory there is a degree of specialization. A pair of these timaliids proved to have a great interest in acorns, which the two either ate or buried, as they did also, incidentally, with peanuts after having shelled them. An individual would use its bill to ram the acorn into the ground, and then quickly hammer it more deeply in, after which it would often fetch a leaf, bits of earth, a small twig or other item and push this into the aperture above the acorn; following this, it would use its bill to make earth from the aperture wall collapse inwards, then rake the site

over with its bill and, sometimes, add a final leaf to the spot. Clearly, such caching behaviour, independently observed to be practised by other captive *Garrulax* species, too, indicates an important adaptation which may be widespread among the larger laughingthrushes of more seasonal habitats, although nothing is known of the way in which food-caching by a gregarious species functions. For example, no information exists on the period of time between burial of the food and its retrieval, and it is not known whether it is always retrieved by the individual that buried it.

There have been no detailed comparative studies of the diets of closely related sympatric and syntopic babblers other than three or more involving three *Turdoides* species, the Yellow-billed, Jungle and Common Babblers, in the Indian region. Where Yellow-billed and Jungle Babblers co-occur, they separate their feeding niches distinctly, the smaller Yellow-billed undertaking far more arboreal foraging and the larger Jungle far more terrestrial foraging. Where Jungle and Common Babblers occur together, the latter being even smaller than the Yellow-billed Babbler, their diets exhibit distinct differences attributable, at least in part, to bill size: the large bill of the Jungle Babbler allows it to take grasshoppers (Orthoptera) and fruit with high efficiency, whereas the small bill of the Common Babbler enables better handling of beetles and of grains of pearl-millet (*Pennisetum glaucum*).

Studies of the Spiny Babbler have revealed an entirely expected pattern in diurnal foraging activity, and one probably typical for most species. The birds begin feeding soon after dawn and reach a peak of activity at around 08:00 hours, thereafter declining steadily towards the midday low between 11:00 and 14:00 hours, when feeding is only occasional. In winter, when the average daylength is 11 hours, and in summer, when it is 13 hours, foraging intensity increases from 14:00 and from 16:00, respectively, and continues until dusk. A similar pattern is found for the Taiwan Liocichla. The average weight of adults of this species is significantly lower during the breeding season than outside it, presumably in part owing to the stresses of feeding young birds and in part because thermoregulatory considerations require higher body mass in colder conditions than in warmer ones. Also on the island of Taiwan, in what is apparently the only study of seasonal differences in foraging patterns of a babbler, it

Very few babblers are known to drink, but this is presumably because few reports ever find their way into print. In some arid-country species the need for water is apparently obviated, although they will visit temporary water sources after rain. Meanwhile, forest babblers, such as the **Black-throated Laughingthrush**, probably drink on a regular basis at rivers and pools, particularly where these are shady and secluded. One timaliid has even been noted to drink from the cups of pitcher plants.

[*Dryonastes chinensis*

was found that the White-whiskered Laughingthrush (*Trochalopteron morrisonianum*) foraged in different parts of the habitat at different seasons, presumably mainly in response to plant phenology. Thus, during the breeding season, the birds foraged both lower and higher than in the non-breeding season, on both shorter and taller plants and smaller and larger trees, and along smaller branches, and they consumed more invertebrates, flower petals and larger food items; moreover, throughout the year, males foraged more often above 8 m than did females.

Foraging flocks of particular species of babbler can move very swiftly from site to site, or they may move very slowly. Size and guild seem to matter here. Small arboreal leaf-gleaners and twig-gleaners tend to be faster-moving, sometimes, indeed, with bewildering speed. The Yellow-throated and Rufous-winged Fulvetas are two such species, and the Chestnut-collared Yuhina is another. The last-mentioned has a predilection for aphid-infested trees, and could it be that at certain times of the year the flocks trap-line when they forage? They certainly must cover relatively large distances in a day, and they belong to the only babbler species known to have irruptive behaviour (see Movements).

In contrast, some of the larger species take their time, especially when foraging on the ground, up to 20 or sometimes more individuals working their way methodically over a patch of forest floor covering several hundred square metres, the operation lasting for many minutes. In the case of some *Turdoides* babblers, notably the skulking "chatterers", the foraging group works its way out into open terrain from the base of thick cover, searching unobtrusively for food, often with one bird posted as a sentry against potential danger, which is a general feature of *Turdoides* (see General Habits), although apparently unreported for other genera. The birds tend to keep within 10 m or so of their nearest group-member, and remain in constant contact by means of low-volume calls. In one study of Yellow-billed Babblers, the average speed of flock movement in the rainy season, with denser vegetation and greater fruit abundance, was 105 m per hour, whereas in the dry season this increased to 134 m per hour, although in a study of the more arboreal Jungle Babblers in the non-breeding season the average speed was 200 m per hour and, on the other hand, groups of ground-foraging Giant Babaxes moved only 300–400 m over the course of an entire day.

It is not particularly clear if babblers in monospecific groups defend territories and, if they do, the methods that they use. The smaller, faster-moving species may not do so at all. A study of Grey-cheeked Fulvetas on Taiwan revealed extensive overlap in the home ranges of groups, with no apparent territorial defence; the size of home ranges of this species varied from 17.8 ha to 31.8 ha. Even the aggressive open-country *Turdoides* babblers, which fight each other on occasion, sometimes have neutral ground where groups feed together for several hours at a time without conflict, at least when not breeding. Certainly, territorial defence becomes impossible when monospecific flocks join mixed-species flocks, many of which are composed largely or completely of babblers; presumably, these "taxonomic" groupings reflect similarity of guild, and involve species with very slightly different niches within the guild. Such mixed flocks are commonest in the parts of the world where babbler species are at their most numerous, from the eastern Himalayas east to South-east Asia. Feeding flocks, however, often require a sentinel, commonly a drongo, a bird well known for its aggression, sharp eyes and distinctive warning call. The theory has been that the drongo benefits by being able to hawk insects flushed by the ground-feeding babblers, and repays this advantage by its vigilance and alarm-calling. This certainly fits the evidence from a study of Yellow-billed Babblers in India, where a nesting pair clearly profited from the presence of a Black Drongo (*Dicrurus macrocercus*), which, although once stealing food from a babbler, drove off every approaching raptor. On the other hand, recent observations in Myanmar of mixed-species flocks dominated by Greater Necklaced and Lesser Necklaced Laughingthrushes have produced evidence that the dynamics of the relationship are less straightforward. There, the Greater Racket-tailed Drongo (*Dicrurus paradiseus*) commonly occurs with a foraging group of the babblers and, indeed, it often gives alarm calls which alert the group to the presence of predators; far from using the foraging flock as "beaters" for its own aerial sallying, however, it also simply harries flock-members for prey that they catch, in some cases chasing an individual for over a minute, striking it in flight and driving it to the ground. The trade-off for the laughingthrushes is evidently worthwhile, although it is difficult to know what they could do about the situation.

The more aggressive *Turdoides* babblers have a solution to this. Although, as just noted, they supply their own sentries, it is clearly more efficient if another species fulfils this function. In South Africa, however, the Fork-tailed Drongo (*Dicrurus adsimilis*), which frequently attaches itself to groups of Southern Pied Babblers, has taken the game one step further. Instead of harrying its companions, it gives an alarm call, a "false alarm", when it sees a prey item about to be taken by one of them, causing the babblers to fly up while it swoops down to steal the item for itself. For small groups of babblers, the benefit of the drongo's services just outweighs the cost of this kleptoparasitism, and the bird is tolerated. On the other hand, for large groups of babblers, in which sentry duty can easily be rotated with little loss to any individual, the drongo becomes surplus to requirements and the babblers drive it off.

In the case of the drongos, it seems well agreed that it is they that seek out the babblers, rather than the reverse. In the case of the mixed babbler flocks in tropical forest, it is possible that there is a general advantage to all participants, and that the convergence happens through a common self-interest. In Sri Lanka, however, the Orange-billed Babbler is a major nuclear species for mixed flocks of birds of any species in Sinharaja Forest, being present in most flocks and then always leading them, but the extent to which it profits by the company is unclear. In the open savannas of Africa, at any rate, there is some evidence that the trade-offs among *Turdoides* babbler species may be more lopsided. Thus, Southern Pied Babblers and the slightly smaller Arrow-marked Babblers have been seen while foraging together in the same group on occasion, but at other times they have been recorded as fighting fiercely, indicating that different degrees of sociability must be determined by different environmental conditions. Similarly, groups of Rusty Babblers commonly follow groups of the larger Brown Babbler, foraging behind and occasionally with them, but always subordinate to them, and from this evidence it would seem that the greater advantage in the association is for the Rusty Babbler.

Apart from their frequent participation in forest bird waves, babblers have been found to exploit other animals in some way as beaters or as sentinels. Rusty Babblers have been seen to join company with francolins (*Francolinus*) and other unspecified birds. Sharpe's Babblers, too, are recorded as associating with francolins, and also with ground-foraging *Lamprotornis* starlings,

Courtship displays of timaliids are varied, generally modest, and poorly known. No display has been described for the **Ferruginous Babbler**, but it is possible that the "sky-pointing" individual in this photograph is involved in some sort of display. Several babbler species are known to cock their heads or point their bills upward during courtship or agonistic behaviour. The most dramatic timaliid displays are seen in species with elongated plumes, such as *Macronus*, or coloured neck-patches, such as *Stachyris*.

[*Trichastoma bicolor*,  
Johor, Malaysia.  
Photo: Morten Strange]

*Campethera* woodpeckers, wood-hoopoes (*Phoebastria*) and *Tockus* hornbills. Southern Pied Babblers form associations with Red-billed Buffalo-weavers (*Bubalornis niger*) and Crimson-breasted Shrikes (*Laniarius atrococcineus*), and have been seen to kleptoparasitize a Brown-headed Tchagra (*Tchagra australis*) and to be kleptoparasitized by hornbills. Brown Babblers often join bird flocks but also associate with parties of dwarf monogeese (*Helogale parvula*). In south Asia, Orange-billed Babblers and Yellow-billed Babblers associate with *Funambulus*

As a general rule, both sexes of babblers contribute to parental duties such as nest-building, incubating eggs, and rearing the brood. Most babbler nests are cup-shaped, but many are domed, especially in those species nesting close to the ground. Thus, the **Spot-breasted Scimitar-babbler**, like most other *Pomatorhinus* species, builds a loose dome with a broad side-entrance. The structure consists of coarse plant fibres such as grasses, dry ferns and leaves. It is placed on the ground, or low in a dense bush, and lined with fine grass and rootlets.

[*Pomatorhinus mccllellandi*,  
Cangshan, Dali,

Holmes]

The **Pin-striped Tit-babbler** builds a ball-shaped nest from dead grasses and leaves (often including bamboo), bark strips, palm strands, and a range of other plant debris and fibres. It usually places this structure in dense low vegetation such as bushes, ferns, vines or bamboo. The individual pictured here seems to have snapped off a piece of dead leaf, perhaps with the intention of incorporating this item in the nest. Alternatively, it may simply be removing debris while foraging; aerial dead leaves are favoured feeding stations for this species, along with several other babblers.

squirrels, and in Sulawesi the Malia does this with other species of squirrel. Back in Africa's tropical forests, the Brown Illadopsis sometimes attends driver-ant columns, and often follows the ribboned rope squirrel (*Funisciurus lemniscatus*).

If the animals with which timaliids associate are used more as beaters than as sentinels, which is incontrovertibly the case with the ants, at least, it has to be said that very few babblers appear ever to indulge in aerial sallying. Yellow-billed, Common and Spiny Babblers do so occasionally, as do the Wrenit, the

White-chested Babbler, the Silver-eared Mesia, the Red-billed Leiothrix, the Fire-tailed Myzornis and the Principe Flycatcher-babbler. The Rufous Sibia has been known to flycatch in captivity, and perhaps all sibilas indulge in this behaviour at times. On the other hand, the habit of jumping to snatch food items, such as overhanging fruit or an insect on an overhanging leaf or branch, is quite widespread in the family.

Drinking is poorly documented for babblers. Many members of the family may not need to do so. Southern Pied Babblers survive in certain areas without drinking, but where they get the chance to drink they take it. Brown Babblers drink during the day and before they go to roost: the flock approaches the drinking pool cautiously, using the cover of thick vegetation, the birds then either all emerging at the water's edge in a row or else drinking one at a time from an overhanging branch. On Luzon, in the Philippines, a Chestnut-faced Babbler has been seen to drink from a pitcher-plant.

Within groups of *Turdoides* babblers, at least, the feeding of one individual by another is an important phenomenon. This behaviour, known as allofeeding, has already been dealt with in some detail (see General Habits). Courtship feeding, another form of allofeeding, is mentioned below (see Breeding).

## Breeding

For most babbler species, it appears that breeding is predictably associated with increasing daylength and temperatures in much of the Northern Hemisphere. At the equator the pattern is less predictable, and breeding may occur in any month, but with greater likelihood at the start of the rains. Study of *Turdoides* babblers in India reveals that, while rains-driven food availability accounts for the timing of breeding in some areas, it does not in others, perhaps owing to the nature of the rain—too hard and continuous in open country to allow for efficient foraging, in spite of the insects that emerge. Babblers in India show two breeding peaks per year, one in spring, probably in response to spring leaf-flush, and the other between mid-summer and autumn, probably in response to monsoon rains.

With these Indian *Turdoides* babblers, non-breeding flocks can sometimes be big enough that they break up into smaller breeding groups which remain on the flock territory and breed

Co-operative breeding is the norm in many group-living babbler genera, including *Turdoides*. In the **Fulvous Babbler**, for example, breeding groups are composed of a monogamous pair assisted by one or two subordinate individuals, usually the offspring of the dominant pair. These helpers contribute to nest-building, incubation, defence against predators, and the feeding of incubating birds, nestlings and fledglings. In this species, as with other *Turdoides*, the nest is a loose cup of twigs and dry grasses, usually placed fairly low in dense thorny bushes.

[*Turdoides fulva fulva*,

Ardea]

independently of each other, but not simultaneously. The many other babbler species that form large winter flocks have not been studied in sufficient detail to determine the pattern of their break-up into smaller constituent groups and pairs, but in some cases there are reports of flocks persisting while some birds begin breeding; these flocks perhaps consist of younger individuals that will not breed at one year of age, or of later-breeding birds. The dynamics of flock break-up, however, appear engaging, as anecdotal evidence concerning the Bar-throated Minla suggests. With this species, flocks of 15–50 individuals have been seen to separate into pairs, all of which remain together in the same tree, the partners of each pair snuggling side by side while facing in opposite directions on a branch, and separated by at least 15 cm from the next pair. Then, with churring and whistling, they alternately bow and stretch the head to the fullest extent, the feathers of the head and neck fluffed out, and frequently reverse their positions, shifting at the same instant so that the two tails are never on the same side of the branch. This can continue for an hour or more without a break, each pair normally ignoring the others, but an individual occasionally leaving its partner and starting to bow to the nearest bird of the next pair, which leads to much scuffling and disturbance.

To the human eye and mind, a flock has a certain informality and randomness, to do with its seemingly variable composition and arbitrary movement through a habitat, which encourages the assumption that individual relationships within the flock may be rather secondary considerations, and that pair-bonds may not be particularly strong or long-term. That this is probably a mistaken notion is suggested by a study of Taiwan Liocichlas, in which it was found that established pairs join winter flocks every day, one hour after dawn, and break down into pairs again after sunset, thereby giving the daytime human observer something of an illusion of the relative importance to the species of group-living over pair-wise association. Studies of other flocking species, in captivity, have suggested that the pair-bond is very strong. Gibson considered that the Red-billed Leiothrix mates for life, and found that members of pairs were extremely protective of each other; one female seemed to nurse her mate back to health after he lost half of his scalp and eyebrow in a scrap. Gibson pointed out that single birds are always nervous and unhappy in aviaries, and that they need to be kept in pairs. Interestingly in this regard, an early

fieldworker in Myanmar, T. R. Livesey, reported of the Dark-backed Sibia (*Malacias melanoleucus*): "I very reluctantly had to shoot a few specimens to authenticate the eggs I took, and for scientific purposes. In doing so the distress shown by the mate of the bird I had killed induced me to shoot it also." Among Wrentits, it has been found that more than 95% of individuals mate for life, the pair-bond usually forming in the first winter of life, between late autumn and early spring. Paradoxically, it may be that it is the very strength of the pair-bonds in babbler flocks that promotes their coherence and stability.

Apparently, only one species of babbler, the Blue-crowned Laughingthrush, has been found to be loosely colonial when breeding, but this trait may prove to be true of certain other timaliids, particularly those which have little or no song. Despite the evidence that some *Turdoides* and *Babax* species share parts of their home ranges, however, it seems that many babblers are territorial, and, at least around breeding time, strongly so. In a study of Jungle Babblers, it was found that the flock usually visited every tree in the territory at least once during the course of a day. Among both Wrentits and Taiwan Liocichlas, both sexes actively defend the territory, which is usually fairly small, in the case of the latter species only some 0.6 ha, and irregular in shape according to the landscape, while that of the Scaly-breasted Illadopsis is about 0.8 ha and the birds are sufficiently site-faithful to be found in the same territory for at least three years. Wrentits use song as a key indicator of occupancy, the male visiting preferred singing perches throughout the day. When intruders are detected, both members of the pair quickly fly to the vicinity and sing, holding the head feathers and tail erect and the wings slightly spread. Longer conflicts usually take the form of chases back and forth along the territorial boundary, but fighting, which involves wing-buffeting and bill-snapping, is rare. When greater tolerance is shown, it is likely that the individuals are related, as territorial division between parents and offspring of this species has been observed, so that offspring come to occupy adjacent territories. So deeply philopatric is the male Wrentit, however, that, once it is established on territory, a shift to another has yet to be recorded.

Territorial conflict appears much stronger with certain species than with others, but the extent to which this perception is the product of observer bias is unclear. The Madagascar Ground-

The nest of the **Golden Babbler** is a ball made of dry leaves, usually including bamboo and grasses. It is often unlined, and placed on the ground or low down in thick vegetation. The clutch comprises 3–4 eggs. Aside from these details very little has been published about the breeding behaviour of this species, despite its wide distribution and relative abundance. This paucity of information applies more generally to small timaliids, suggesting that they represent good targets for future fieldwork.

[*Stachyridopsis chrysaea chrysops*, Fraser's Hill, Malaysia. Photo: Ong Kiem Sian]

The **Golden-fronted Fulvetta** is a restricted-range species inhabiting the mossy, rain-soaked, mid-montane forests of Sichuan and Guangxi, China. Here, it builds a ball-shaped nest with an outer layer of green moss, presumably as camouflage. The inner layers and lining of the nest are constructed from the dry dead leaves of bamboo, along with other plant fibres. This structure is fitted snugly and inconspicuously amongst moss or creepers low down on tree trunks, sloping banks or in clumps of ferns or orchids. The scant information available suggests that a clutch of around 4 eggs is laid, and the chicks fed by both adults of a pair.

[*Pseudominla variegaticeps*,

Holmes]

hunter is a pugnacious creature, highly territorial and often in dispute with other males, and the Cape Rockjumper (*Chaetops frenatus*) has frequent brief territorial confrontations, during which the head is held up and the tail is fanned so as to show off the conspicuous tips. Chinese Hwameis are fiercely aggressive at all times: a captive male that sees another male goes into paroxysms, quivering its wings, fluffing its body feathers, uttering low cat-like mews or standing erect on its perch, performing hula-like movements and uttering chuckling notes as it dips its tail and nods its head in rhythmic unison, or else it ostentatiously jumps up and down on the perch with much noise. In a display that seems to proclaim territorial rights, the Rufous-chinned Laughingthrush, giving a loud throaty bubbling, perches with the body held to one side, the tail pointing to the opposite side, and the head and neck stretched upwards and forwards, with the bill slightly raised; it then performs a series of rapid single pivoting and ducking movements from side to side, dipping and raising the head as it swivels the body, at the same time swinging the tail across with a vigorous jerky movement that shows off the conspicuous coloration of the throat and tail tip.

Among *Turdoides* babblers, confrontations at boundaries take the form of extended chorusing and displaying, the rivals usually 30–50 m apart. Brown Babblers partly spread their wings, bow, and fan and close the tail as they chorus, sometimes turning the body widely from side to side and flicking the wings with each call note. With Arrow-marked Babblers, flocks that cross the boundary line are quickly chased back, but, when group sizes are unequal, larger groups may cross the boundary and chase the smaller group deep into its own territory. Sometimes, as noted earlier with regard to interspecific confrontations (see General Habits), an individual from each side steps forward to take the confrontation further, and the two fight while the others look on. This has been recorded for Southern Pied Babblers and Rusty Babblers, as well as the Arrow-marked Babbler.

In contrast, courtship displays of the Timaliidae are far less well documented or understood, because they are, of course, con-

siderably less frequent and more discreetly performed. Yet the anecdotal evidence suggests that they are as varied as the plumages and shapes of the babblers themselves. Singing is for many species the primary form of display, and, as indicated earlier (see Voice), an unmated male Wren-tit has a far higher song output than a paired male. Many, and perhaps most, singers deliver their songs together with other signals. As examples, the Palawan Ground-babbler stretches its head up at 45°, the Malia cocks its tail high, the Brown Illadopsis puffs out its throat feathers and displays its white moustaches, the Black-capped Illadopsis opens its wings, the Fluffy-backed Tit-babbler jerks its back plumes, and the Striated Laughingthrush raises its crest. Both the Flame-templed Babbler and the Coral-billed Scimitar-babbler perch very upright, and the latter puffs out its throat. The Naga Wren-babbler (*Spelaornis chocolatinus*) puffs up its head and breast feathers and jerks its body up and down, while the Spotted Wren-babbler, *Elachura*, opens and quivers its wings. The Plain Laughingthrush tilts its head rhythmically from side to side, puffs out its feathers and holds its tail above its head, the Rufous-chinned Laughingthrush hunches its back, depresses its tail and puffs out its body feathers while bowing and turning around, and the Rufous-necked Laughingthrush raises the bill upwards, flicks the wings, and depresses and flirts the tail from side to side. The singing Yellow-billed Babbler spreads the tail and flicks the wings as it pivots from side to side. Finally, the Silver-eared Mesia continually flirts its wings, and the Red-billed Leiothrix quivers its wings and fluffs out its body feathers.

The two last-mentioned have courtship displays that have, apparently, been recorded only in captivity. The male Silver-eared Mesia holds a grass stem and stretches bolt upright, crown feathers erect, in front of the female. Both then raise the wings above head-height, the female also sometimes holding grass, and both slowly bow the head and bob the tightly folded tail. A male Red-billed Leiothrix, evidently somewhat earlier in the courtship cycle, danced around and around a female in the manner of certain gamebirds (Galliformes), swaying his sleeked, up-pointed head

Incubation in babblers normally begins with the last egg so that hatching is synchronous. Both males and females take part in incubation, changing over at the nest very furtively, with a minimum of fuss or vocalizing. In some species the overnight shift is always undertaken by the female. This information is lacking for many babblers, including the **Rufous-crowned Babbler**, because they are poorly known and sexually monomorphic. As with most *Malacopteron*, the nest of this species is a simple cup, usually supported by vertical stems low down in the dense understorey of evergreen rainforests.

[*Malacopteron magnum magnum*, Malaysia.  
Photo: Roland Seitre]

and forebody from side to side, showing off the throat and breast colours, and displaying the pattern of both wings by leaning towards her, lowering the near wing and raising and inverting the far wing so that it showed over his back. In a third unique observation involving a captive timaliid, a male Black-chinned Yuhina (*Yuhina nigrimenta*) crept through some bushes while holding his crest down, wings half-spread and quivering, tail spread, and flank feathers fluffed, giving him an odd flattened appearance, during all of which he made a hissing noise. Later, he sang and, on the last note of the song, rotated forwards and downwards on the perch, with wings and tail spread to their fullest extent, hanging upside-down like a miniature bird-of-paradise (*Paradisaeidae*), before returning to his original position by swinging back up in a complete circle.

Just as unexpectedly, a Striated Yuhina (*Staphida castaniceps*) soared 6–10 m into the air and then sailed down on outstretched wings to some lower bushes, presumably in a display intended to impress a watching female. There seem to be no other reports of aerial displays of this sort in the family, although lightning-fast pursuits through dense vegetation have been recorded for the Rufous Sibia, during which the male pecked repeatedly at or near the female's cloaca, and for the Sulawesi Babbler (*Trichastoma celebensis*), which ended with both sexes remaining motionless with the head held in a strange way against the neck.

Less acrobatic displays, involving bowing and nodding of the head, flirting and spreading of the wings, and constantly vocalizing, have been seen to be performed by the Black-throated Laughingthrush and Greater Necklaced Laughingthrush on the ground. A captive Masked Laughingthrush, while collecting nest material, fluffed up the head and flank feathers and held the body horizontal so that the chestnut coloration of the ventral area was emphasized, almost as an invitation to copulation. Two courting Chestnut-winged Babblers sat 0.5 m apart on branches about 3 m up, where they pointed the bill upwards, displaying the bright blue throat patches, and uttered a long series of soft *Stachyris* "poop" calls (see Voice), and two courting individuals of the closely related Chestnut-rumped Babbler raised and lowered the head and bowed deeply to each other. In another interesting courtship display, a male and female of the Madagascar Groundhunter

strutted silently around each other in meandering circles for several minutes, the tail cocked vertically, looking like miniature rails (*Rallidae*). The Thrush-babbler is reputed to display in a little arena, but this requires confirmation.

Courtship feeding is practised by babblers, but how widespread it is in the family is not known. It is regularly performed by the Brown Illadopsis and the Spiny Babbler, and has been observed several times in captive White-throated Laughingthrushes, the female approaching the male in a slightly crouched posture, with the feathers fluffed and wings shivering as she was fed. When a male Southern Pied Babbler caught a large grasshopper on the ground, he was quickly joined by a female, which took the prey and ate it, and the pair then copulated. Copulation itself is not commonly seen or, at least, has been infrequently documented for timaliids. It takes place very rapidly in the case of the Chestnut-collared Yuhina and very unostentatiously in the case of the Fulvous Babbler, although single observations of such activities do not necessarily, of course, reflect normal events. Lack of ostentation, however, is certainly a feature of copulation among Arabian Babblers, the female of which deliberately leads the courting male to a secluded spot in order to test the degree of his dominance. If another male follows and is not fully challenged and driven off, she then knows that a question-mark hangs over the first male's control of the group, and she may well then make herself available to his "second-in-command" while still in her fertile period.

Among most *Turdoides* babblers, breeding is co-operative, with usually several helpers at the nest, these generally consisting of offspring of the dominant breeding pair. These helpers contribute to the breeding effort in various ways, by supplying nest material, incubating, bringing food to the nest, including to the incubating female, keeping watch, and supporting the offspring, but the amount and type of assistance varies with species, context and status; among certain Indian *Turdoides*, for example, first-years may do many helpful things, but they never take part in incubation. Moreover, there can be interesting complications, as when two females lay in one nest or one female lays a clutch sired by two fathers. As mentioned previously (see General Timaliids), some 14% of the Timaliidae remain in groups all year, and many of these species are likely to be co-operative breeders. The

Babbler chicks hatch blind and naked, sprouting feathers around four days after hatching, and opening their eyes perhaps a day later. The nestling period tends to be relatively short in many small or medium-sized species. In the **Yellow-eyed Babbler**, 3–5 eggs are incubated by both sexes, and once these have hatched the chicks are fed, again by both sexes, for a further 12–13 days. The nestlings shown here appear to be around ten days old, and equal in size due to synchronous hatching.

[*Chrysomma sinense hypoleucum*,  
Karnataka, India.

Photo: Vivek Sinha/VIREO]

Cape Rockjumper is a facultative co-operative breeder, and this appears to be true also of the Giant Babax, where helpers do no more than defend the nest. Perhaps no timaliid species is obligate to the point of being unable to breed unless a group is involved, although the willingness of captive Blue-crowned Laughingthrushes to assist in the rearing of the young of other species with which they are housed suggests a high degree of "hard-wiring" which may, in fact, be typical of many of its relatives.

The most extraordinary breeding system yet discovered among the babblers is that of the Taiwan Yuhina. In this species, each group consists of 1–3 communally nesting, socially monogamous pairs, some with a single unmated helper, and each is headed by a male the head, wing and tail lengths of which exceed those of other males in the group, and which alone sings in territorial defence. Female rank relates not to body size but simply to her mate's rank. More than one female lays eggs in the nest, and in one study 20% of offspring were from inter-group extra-pair fertilization, which was detected in 50% of all broods, and a further 20% of offspring were from intra-group extra-pair fertilization, found in 67% of all broods. New individuals joining parental groups are either male offspring from previous breeding seasons with a non-relative mate, or an unrelated pair. Larger groups do not have higher nest success rates, nor do they produce more fledglings, but, instead, they reduce their investment in each breeding attempt by laying fewer eggs, thereby lightening the group workload of incubation and food-provisioning. Apart from *alpha* males, individuals in larger groups have higher survival probabilities, this being especially so for females, because their incubation load is much lighter. Larger groups may also build nests and reneest faster than do solitary pairs, and occupy better-quality home ranges in terms of possible nest-sites, food availability and tree cover.

For most babblers, the roles of nest construction, incubation of the eggs, and brooding and feeding of the young are shared between the male and the female, although the relative proportions vary with species and individuals and also with time. Nests are usually open cups, some shallow, some deep, lined with roots and fine stems and camouflaged with moss and lichen. Those species that nest closest to the ground have a domed nest: thus,

members of the genera *Pomatorhinus*, *Pnoepyga*, *Macronus* and probably *Rimator* normally or always add a dome, and species in *Stachyris*, *Stachyridopsis* and *Pellorneum* often do so. The size of the nest and the size of the bird may determine the time taken in the making of the structure; at least, the Grey-cheeked Fulvetta constructs a nest in 3–4 days and the Black-chinned Laughingthrush (*Strophocincla cachimans*) in 7–15 days. Replacement nests, after loss of the first nest, are usually built much more quickly. In co-operative *Turdoides* babblers, the number of helpers appears to have no effect on the speed of construction. A Wrenit's nest, taking 3–10 days but normally 6–7 days to build, involves four stages: the building of a cobweb framework, of the platform, and of the walls of the cup, and the adding of the interior lining. The Dark-fronted Babbler, confined to southern India and Sri Lanka, appears to be unusual, and perhaps unique in the family, in building many "cock-nests" (unlined nests that may or may not be selected for true nesting), so many in fact that one observer originally thought that the species was colonial. It is not known, however, if these are built only by the male, as the term "cock-nest" implies.

The limited evidence suggests that, after the nest is completed, there is a short lull, as with other passerines, of up to three days before the first egg is laid. Black-chinned Laughingthrushes lay their eggs between 06:00 and 08:00 hours on successive mornings. The eggs are highly variable in coloration, from pinkish-white to rich greenish-blue, buffy cream and reddish-brown, with or without maculations, but the shells commonly have a fine-grained texture producing a smooth surface with variable gloss. Clutch size varies more predictably with latitude. For example, many tropical species lay only two eggs, but there is a general tendency towards larger clutches in more northerly species, with six eggs recorded for such species as the Chinese Babax (*Babax lanceolatus*), the Plain Laughingthrush and the Chinese Bushdweller, although the *Turdoides* babblers often do better still, perhaps because more than one female is involved. In the case of both the Wrenit and the Taiwan Liocichla, each egg weighs about 13% of the adult female's body weight.

Incubation begins with the last egg, except for some *Turdoides* babblers. The Arrow-marked Babbler begins with the first egg.

At nests of the Wrenit, the female incubates for longer spells than those contributed by the male, and she sits also at night, the male taking the first and last daytime shifts to allow her up to 30 minutes of foraging. Change-overs are normally preceded by a single or double song by either sex, and the birds often approach and leave the nest along the same concealed route, very surreptitiously. All of this is probably typical for other babblers, and is supported by evidence from studies of the Taiwan *Liocichla* and Grey-cheeked *Fulvetta*, but apparently it is only the female that incubates at nests of the Pale-breasted *Illadopsis* and Abbott's Babbler. With the Black-chinned Laughingthrush, fresh eggs weigh 5.2 g, falling to 4.2 g on the 15th day of incubation, and hatchlings weigh 3.5 g.

After hatching, nestlings of the larger species are brooded intensively in the first few days, at least. Black-chinned Laughingthrushes decrease the amount of brooding daily through to day 7, and thereafter, for a further seven days or so, they brood only weakly, and often simply to keep the chicks dry during rain. Similarly, the Taiwan *Liocichla* broods until day 8. The Wrenit, however, broods its chicks until they leave the nest. Presumably, size is important, such that the smaller the chick the greater the thermoregulatory need. Both sexes feed the nestlings at intervals of 15–30 minutes, this decreasing to as few as five minutes towards the end of the nestling period. There are various other statistics. For example, in 65.6 hours of observation at a nest of Snowy-cheeked Laughingthrushes, the parents fed their seven-day-old nestlings 521 times at a combined frequency of 7.9 times per hour, increasing from 3.2 per hour on the first day to 11.05 per hour on the day of fledging; 35.9% of the provisioning was done by the male and 58.3% by the female, the remainder being unknown, and faecal sacs were removed at a rate of 6.9 per hour. Most babblers, incidentally, swallow the sacs of their nestling. In a study of Arrow-marked Babblers, the young were fed by all members of the group, but unevenly: in one instance, 74% of feeds were delivered by three adults and 26% by another three, and each nestling received 1.3–4.4 feeds per hour, the average being 2.4 feeds. Although helpers make no difference to the speed of nest construction, they do have an influence on the speed of nestling development, such that larger groups fledge their young sooner than do smaller ones. With Arabian Babblers, it has been

suggested that these fast-growing young are the beneficiaries of a serious competition among their food-providers, since provisioning is used also as a means of establishing rights of possession and of improving social status within the group.

Blind and naked when they hatch, babbler chicks begin to sprout feathers on or around day 4 and open their eyes on day 5, progressing as do other passerines. The nestling period of both the Wrenit and the Yellow-billed Babbler is roughly 14 days. Birds of most species, even the Wrenit, may not be able to fly properly at this age, but, being out of the nest, they are capable of clambering around adeptly in twigs and branches. The average weight of fledgling Taiwan *Liocichlas* is 20.5 g, equivalent to 68% of the adult female's weight. An Arrow-marked Babbler in captivity left the nest at 14 days, when it weighed 46 g, 53% of the adult weight. It could fly a little at 16 days, and by 20 days it flew fairly well, but it did not sit out in the open until it reached 26 days, at which stage full feather growth was complete, and it was still being fed by the parents at 45 days. Grey-cheeked *Fulvettas*, the nestling period of which is only around nine days, feed their fledglings for 40–65 days after the latter have left the nest, and Wrenits feed theirs for up to 41 days. In the case of the Wrenit, young from different broods often move together in groups of up to five individuals, from ten weeks after fledging.

The Black-chinned Laughingthrush has been found to pull its nest to pieces after the fledging of the young, or if it is robbed or discovered and disturbed before egg-laying, and the species will even destroy other nests in the same tree. Although this habit appears to be unrecorded for other species, it may be an anti-predator device. Predation is certainly the main cause of nest failure among babblers, which have developed a wide repertoire of distraction displays by way of response. A Spot-necked Babbler near its nest scurried along the ground with its wings outspread and its back feathers ruffled, and a Chestnut-rumped Babbler rapidly hopped along with both wings raised vertically above its head, as if it was unable to fly. At least two species of *illadopsis* perform the "rodent-run", and the Black-capped, Brown-capped and Abbott's Babblers all perform broken-wing displays when disturbed at the nest. Further, and most remarkably, when one breeding adult Coral-billed Scimitar-babbler was mist-netted, two others of the species circled around the observers while making

*Reinwardt's Babbler* is a typical *Turdoides*, breeding in co-operative groups and raising small broods of 2–3 eggs in bulky open-topped nests. There are no data about provisioning in this species, but in congeners the young are fed unevenly by all group members. Some adults, and not necessarily the parents, contribute the bulk of provisioning visits, and each nestling receives 1–4 feeds per hour. It has also been shown that larger groups provide food at a higher rate than smaller groups, resulting in shorter nestling periods, and a consequent reduction in predation risk.

scolding calls and feigning injury, a strange reaction unless, perhaps, the captured adult was in fact an offspring of theirs.

Recently, one observer, F. Peacock, reported a type of distraction behaviour which, if the interpretation is correct, is again remarkable. A small breeding group of Southern Pied Babblers, consisting of an adult pair and an individual in immature plumage, had young in the nest and, every time one of the adults found a food item large enough to be worth delivering to the young, it would hop up to a perch and give a few calls. These calls would cause the immature to fly at once almost to the observer's feet, where it would forage half-heartedly while keeping its eye on him. Meanwhile, the adult would fly to the nest, carrying the food item with it. This happened six times in a period of 40 minutes, and Peacock had "the distinct impression" that the immature was being sent on a mission to distract him, the human observer, from noticing what the adults were doing, in an attempt to keep the presence of the nest secret. As soon as the adult returned from the nest, the immature left him to join it.

None of this is proof against brood parasitism, and babblers are major targets of various species of cuckoo. As many as 24 timaliid species are known to be victimized by *Clamator* cuckoos, which are particularly frequent parasites of *Turdoides* nests. For example, 7.8% of Arrow-marked Babbler nests accommodate the eggs and young of Levaillant's Cuckoo (*Clamator levaillantii*). The Streaked Laughingthrush is apparently parasitized by three different cuculids of two genera, the Jacobin Cuckoo (*Clamator jacobinus*), the Large Hawk-cuckoo (*Cuculus sparveroides*) and the Indian Cuckoo (*Cuculus micropterus*). Parties of smaller babblers, at least, will mob cuckoos, distinguishing readily enough between drongos and drongo-cuckoos (*Surniculus*). The Wrenit's resistance to brood parasitism by Brown-headed Cowbirds, expressed in terms of refusal to leave the eggs unguarded, is so strong that researchers sometimes have physically to remove the sitters, and there is a high rate of rejection of cowbird eggs and young and abandonment of parasitized nests.

Nesting success is variable, but the data are too few to be meaningful. It has been recorded, for example, at 75% for the Giant Babax, 57% for the Common Babbler, 42% for the Taiwan Yuhina, 42% for the Yellow-billed Babbler, 40% for the Plain Laughingthrush and 40% for the Jungle Babbler. In one study of

Grey-checked Fulvettas, natural mortality was determined as 34% per year, attributable mainly to cold weather in January and February. In another study of this species, typhoons were identified as a second cause of mortality, accounting almost entirely for juveniles, although severe typhoons kill adults, too. Almost certainly, these values diminish among babblers in climatically more stable environments in South-east Asia.

Meanwhile, the rest of life beckons for youngsters that have survived beyond fledging. For Wrenit's, with their limited flight capacity and dense low habitat, dispersal can be problematic, and the distance that the young birds travel from the natal nest-site to the site of their first breeding attempt is less than 400 m. Non-breeding individuals, or "floaters", occur in high numbers in years following those with high productivity, and also in years with high breeding densities, and adults appear to show some tolerance of wandering juveniles and family groups at the end of the breeding season and in winter. Among Indian *Turdoides* babblers, juveniles usually stay in their natal groups, but there has to be dispersal at some point, and five out of 104 fledgling Yellow-billed Babblers in one study joined neighbouring groups as early as 40 days after fledging, while others, mainly females, were evicted over time by pressures within the group.

The pattern of socialization in these Indian *Turdoides* is predictable. During the immediate post-fledging period, for about a month, the juveniles spend most of their time being fed by older birds and avoiding being preyed on. Then they begin to move with the group and forage in part for themselves, and they also start play activities and lose their position at the centre of the roost (see General Habits). The next few months are ones of "adolescence", during which they show signs of social indiscipline such as chasing food-carrying adults, pecking one another aggressively and disrupting the roost. This, in turn, declines over the winter months, and by the first summer their behaviour is similar to that of older group-members, although they rank low in terms of sentinel behaviour, allopreening and movement initiation.

This all sounds reasonably comfortable. As an insight into the cut-throat pressures of life in a babbler family, however, a story based on work being undertaken by A. Ridley on Southern Pied Babblers is sobering. In one post-breeding family group that

Brood parasitism by cuckoos is a significant feature of breeding in babblers. Twenty-four timaliid species are known to be parasitized by *Clamator* cuckoos, and this number will doubtless rise with further research. The risk seems to be highest in *Turdoides* babblers. In a study of the Arrow-marked Babbler (*T. jardineii*), for example, Levaillant's Cuckoo (*Clamator levaillantii*) was shown to parasitize 7.8% of the nests. A juvenile of this cuckoo is shown here in the nest of another *Turdoides*, the **Brown Babbler**. Smaller babblers are targeted by cuckoos such as *Cuculus* and *Surniculus*.

Ridley followed, the runt, a tiny female from a brood of four, was continually being left behind. Its parents, the group's dominant pair, never attempted to help it, leaving it to the care of two subordinate birds. After a week, the runt was strong enough to keep up with the group as it moved between sites, but only as a result of the subordinate birds' attention. Then, before the first brood was a month out of the nest, the dominant pair started to breed again. This brought an upsurge of competition among the fledglings because, with one adult now incubating, only three adults were available to feed them. Only one of the second brood survived, and the parents put almost all of their effort into this new fledgling. As a result, the older fledglings began to lose weight, the playfighting stopped and a new begging intensity began, this abating only when the rains finally arrived and the food supply abruptly increased. The single surviving fledgling from the second brood quickly reached parity with his older siblings and began playfighting with them. Leaving provisioning to the subordinates, the two partners constituting the dominant pair fed themselves up in order to produce a third brood. The first brood was now old enough to help with the feeding of the new nestlings, but this triggered new strife among them, one individual wrestling food from another so as to be the one to feed it to the nestlings, and they established a hierarchy of their own. Eventually, one older sibling, through sheer persistent one-on-one aggression, forced its nearest rival to quit the group altogether. None of the adults interfered. Over the following few days the evicted sibling lost weight and condition, reverting to that of a month-old fledgling, but for two weeks he never stopped trying to rejoin the group. Eventually, the aggressive sibling desisted and the evicted bird rejoined the group, but he was now totally subordinate.

In the following year, one of the group's subordinate adults that had given most help to the first and second broods was evicted by the dominant male, since the benefit to the latter of evicting it was greater than the benefit of the quality of help that the evicted bird could then provide. The evicted babbler had helped to maximize the dominant male's genetic standing by contributing to the group's growth in size, but he had thereby also sealed his own fate, since the larger group was seen by the dominant male as sufficient to help with the season's new crop of offspring, meaning that his subordinate, always something of a threat to his status, could be safely thrown out. We can now see rather more clearly that it was hardly a happy family that he was leaving behind.

## Movements

Babblers, at least as the family is constituted in the present treatment, are highly sedentary birds. None of them undertakes a long-distance migration such as is typical of certain species of, for example, Old World warbler and chat. The great majority of timaliids, 75% of the species, are residents, while a further 10% have been either reported as making or inferred to undertake elevational displacements without proof ever having been furnished. This leaves 12% for which elevational movements are usual, if nearly always minor, and 3% which conduct other, minor types of geographical shift.

Into this last category go four African *Turdoides*, which respond to drought or rains with local short-distance migrations, regular or sometimes nomadic, and three other species. These are the Chestnut-faced Babbler of Luzon, in the Philippines, for its records from the migration bottleneck at Dalton Pass, where it presumably would not occur except as a bird on the move; the Chestnut-collared Yuhina for its curious irruptions every few years into Hong Kong, movements which presumably occur throughout its range but have not been recorded elsewhere; and the Blue-crowned Laughingthrush, which has an alarming habit, particularly as it is so highly threatened (see Status and Conservation), of disappearing from its single known surviving site for the period from August to March. The description of the White-hooded Babbler as a local migrant in Kaziranga National Park, in north-east India, is surprising and does not seem to refer to elevational displacements. Similarly, records of the Chinese Bush-dweller in the Korean Peninsula in winter cannot easily be attributed to downslope movements and perhaps involve a more general dispersal in the harsh sub-Siberian winter.

There is also an interesting observation made by the English admiral and naturalist H. Lynes, who noted on the labels of some April specimens of Chinese Hwameis, now in the American Museum of Natural History, that the birds had been singing in the tops of a clump of big willows in a plain "a mile from any other trees" and with "testes scarcely if at all enlarged", and were therefore "obviously on migration". Such a thing has not been recorded for the species otherwise, and it is equally plausible that the individuals in question were, in fact, recent escapees from local bird markets and had dispersed into the local environment.

Elevational movements in the Himalayas and associated ranges have been reported for a good number of species, but not always in a way that allays suspicions of seasonal variation in

Nest hygiene is of paramount importance in babblers, as it is for all passerines. For species with dome-shaped nests, such as the **Pin-striped Tit-babbler**, the removal of faecal sacs is essential to minimize the build-up of excrement in the nest cavity, and the associated risk of disease. In species with open nests, the removal of faeces is probably as much to do with minimizing the accumulation of eye-catching droppings at the nest rim, something that may attract predators. In timaliids, both sexes take responsibility for removing faecal sacs, either eating them directly, or disposing them some distance from the nest-site.

Babblers are often victims of mankind's exploitation.

Many forest species are in retreat due to habitat destruction, while the most beautiful species, or the most powerful songsters, are often trapped and sold as cagebirds. Occasionally, however, babblers benefit from mankind's benevolence, with a few species taking scraps left out for them at human settlements. Here, a squirrel shares a Chinese bird table with a **Giant Laughingthrush**. This handsome species, one of the largest timaliids, occurs in forest and scrub in mountainous regions of south China and Tibet.

[*Ianthocincla maxima*,

detectability or field effort. Nevertheless, they are fairly well documented for the following species: the Golden-breasted and Ludlow's Fulvetas, the Stripe-throated, Rufous-vented (*Yuhina occipitalis*), White-naped (*Yuhina bakeri*) and Whiskered Yuhinas (*Yuhina flavicollis*), the Sickle-billed Scimitar-babbler, the Rufous-throated (*Spelaeornis caudatus*), Spotted, Scaly-breasted, Nepal and Pygmy Wren-babblers, the White-throated, Streaked, Spotted, Scaly, Blue-winged, Variegated, White-whiskered, Black-faced and Chestnut-crowned Laughingthrushes, the Bar-throated and Red-tailed Minlas, the Red-billed Leiothrix, the Rufous, Black-headed and Beautiful Sibilas (*Malacias pulchellus*), the Blue-winged Siva, the Hoary-throated and Streaked Barwings (*Actinodura souliei*), the White-browed and Black-eared Shrike-babblers and the Fire-tailed Myzornis. In Africa, vertical movements by the Bush Blackcap and the Drakensberg Rockjumper (*Chaetops aurantius*) have been documented, and there is some evidence that the Mountain Illadopsis, too, may make minor displacements.

Some of the Himalayan records derive entirely from Bhutan, as a result of detailed mapping work, although there are a number of other indications from long-term projects in various protected areas. The nature of the displacements, however, is by no means clear. In some cases, as typified by the Streaked Laughingthrush and Streaked Barwing, they occur only in hard winters or in response to particularly bad spells of weather. In the great majority of cases, the evidence is that the movements are minor, and sometimes it appears that they are made by only part of the populations, for example those at higher elevations or else, perhaps, younger birds within the population, and so on; again, this could be local in nature, rather than a constant pattern throughout the birds' ranges. There are two cases in which the species in question, the Stripe-throated Yuhina and the Fire-tailed Myzornis, having shifted downwards in winter, reportedly follow the flowering of trees in a steady springtime upward movement, and the Chestnut-crowned Laughingthrush is also described as moving back upslope progressively, albeit not in relation to flowering.

In general, the list is reasonably predictable. The presence of six *Trochalopteron* laughingthrushes is hardly surprising in view of the fact that species in this genus tend to occur at higher elevations than do many others in the family, and for the same reason one may have expected several other high-altitude members of *Fulvetta* besides Ludlow's to be listed. Four *Yuhina*, three

*Malacias*, *Pseudominla* and *Myzornis* are all predictable, given their partial dependence on flowers not for nectar alone but also for insects, and this may also explain the presence of two *Actinodura* species. Perhaps the oddest members of the list are the tiny tailless *Pnoepyga* wren-babblers, which nonetheless undertake what appear to be the most notable vertical migrations of all. The Nepal, Scaly-breasted and Pygmy Wren-babblers are subject to considerable movements, the Scaly-breasted being found in the Dehra Dun valley and Corbett National Park, in the north Indian state of Uttaranchal Pradesh, only in winter, and the Pygmy regarded as an uncommon winter migrant in both Nameri and Kaziranga National Parks, in Assam. Perhaps it is precisely

**The Rufous-fronted Laughingthrush** is a restricted-range species endemic to the Indonesian island of Java. It is locally common in broadleaved evergreen forest in the montane zone, often joining other passerines in mixed-species foraging parties. Like many Javan birds, it suffers from heavy trapping pressure for the cagebird trade, a threat that has apparently caused declines even within major protected areas, such as Gunung Gede-Pangrango National Park. It is fairly common, however, in less-accessible mountainous regions, where habitat remains relatively secure. Its conservation status is currently defined as **Near-threatened**.

[*Garrulax rufifrons*,  
rufifrons,  
Java.  
Photo: Roland Seitre]

because of the small size of these timaliids that they are driven by thermoregulatory necessity down the mountain slopes as winter temperatures drop. What is difficult to credit for so unaerodynamic a bird as a *Pnoepyga* is that these movements can proceed in any way other than a series of very short flights and a lot of hopping.

Apart from these, the two species showing the strongest seasonal altitudinal displacements are the Red-billed Leiothrix in Asia and the Bush Blackcap in southern Africa. The leiothrix appears to make a post-breeding descent throughout the Himalayas, in rather rapid shifts that take place in early November, and

moves back up again in late April. The post-breeding wanderings of this species in Hawaii, where it has been introduced, suggest that this vagility, which sometimes involves upward movements rather than downward ones, is an important part of the dispersal process. Ringing has shown that Bush Blackcap populations breeding in the high Drakensberg can shift downwards over a linear distance of as much as 300 km, records from outside the normal range suggesting that some individuals, perhaps mainly dispersing juveniles, overshoot. Even so, in neither case is it clear that the entire populations supplying the migrant birds shift their ground; on the contrary, it may be that some individuals remain at their high-lying breeding elevations throughout the year.

### Relationship with Man

Skulking, wary denizens of forest undergrowth or dense scrub, most babblers are far too removed from the human environment to figure in any significant way in human cultures or economics. Some are equally unobtrusive in their coloration, leaving even less opportunity to come to man's attention except through their songs, which, although often attractive, are generally not sufficiently special to draw great interest.

The great exception is the Chinese Hwamei, the song of which is among the best and most powerful to be heard in Asia. Because they are extremely territorial and pugnacious, the males are very easily caught. The trapper uses a divided cage with a captive male in the inner compartment; the cage is left in the brambles, with the outer trapdoor set, and, when the captive male sings, the free male immediately responds and approaches, entering the cage and being caught. The birds are commonly used simply as cagebirds, and apparently make excellent pets, but they were, at least formerly, pitted against each other in physical fights, as a form of "entertainment". Perhaps because of this, the species did not always have a favourable association, as La Touche reported:

"At Chinkiang, on the Lower Yangtse, the carrying of a Hwamei in a cage, with the large hanging hook pointing forward, indicated in the later days of the Manchu Dynasty that the owner was a local bully; and I have heard it

**The White-chested Babbler** occupies a classic Sundaic range, extending from south Myanmar to the islands of Sumatra and Borneo. Throughout this range it is a specialist of forested riverbanks, and is often seen hunting for insects on exposed roots and rocks at the water's edge, or darting out to catch insects flying over its surface. This narrow niche presumably results in a relatively low overall population size, especially given the rapid rate of deforestation. However, the species tolerates degraded habitats and overgrown plantations, and is therefore not immediately threatened. It remains fairly common and is classified as Near-threatened.

[*Trichastoma rostratum rostratum*,  
Panti Forest Reserve,  
Malaysia.  
Photo: Ong Kiem Sian]

**The Grey-breasted Babbler**, a Near-threatened swamp-forest specialist, is generally scarce in lowland forests of Peninsular Malaysia, Borneo and Sumatra. It is threatened by the widespread destruction of swamp forest, but survives in degraded habitats. It relies on the long-term protection of peat-swamp reserves, including Tanjung Puting and Gunung Palung National Parks, Borneo. Usually included in *Malacopteron*, its unique head pattern, morphology and behaviour suggest that it warrants isolation in a monospecific genus.

[*Ophrydomis albobularis moultoni*,  
Bentuang-Karimam  
National Park,  
West Kalimantan, Borneo.  
Photo: Doug Wechsler/  
VIREO]

The **Giant Babax** is a Near-threatened, restricted-range species confined to south-east Tibet (part of the Southern Tibet Endemic Bird Area). Its global population, currently estimated at 120,000 birds, is thought to be declining because of the loss of key breeding habitat: high-altitude woodland and scrub. This is being converted to grazing lands and removed for firewood.

The species reaches a maximum length of 33.5 cm, a maximum weight of 160 g, and a maximum altitude of 4600 m. In the entire timaliid radiation, only one species is larger, and no other species occurs higher above sea-level.

[*Babax waddelli waddelli*, Tibet.

Photo: Walter Mankel]

said that people 'not in the swim', daring to carry their birds in this way, were likely to be attacked and have their birds taken away from them. For this reason, in those days, as recently as 1905, it was not a bird for respectable Chinkiang people to carry about."

Today, however, it appears that the "fighting" is for the most part in the form of song-fighting, with keen competitions held to discover which bird is the best singer. Many individuals of this species captured in China are traded via Hong Kong to Singapore, where competitions certainly were, until recently, particularly intense; moreover, such was the extent of the interest that, grasshoppers being a song stimulant, professional grasshopper-collectors on the island would travel to adjacent Johore to bring back supplies for the fanciers. The hwamei clearly is, however, a fighter of sorts, because despite the enormous trapping pressure, not only in China but also in Vietnam, the species remains tolerably common and recovers quickly once trapping pressure is removed.

The glorious colours of the laughingthrushes have been a considerable attraction to bird-fanciers down the years, and the fact that many species come from remote parts of Asia serves only to make them more attractive. In Germany, where there is a long tradition in the keeping of exotic cagebirds, many species of the old extended genus *Garrulax* (see Systematics), and, indeed, other babblers about which we know little in life, have been kept and their breeding and behaviour documented, although one of the best studies of a captive population of the super-popular Red-billed Leiothrix was made by a Canadian aviculturalist, Gibson.

These same species are considerable drivers of ecotourism in parts of Asia. Some of the large laughingthrushes, such as the Giant and Spotted Laughingthrushes, are so extraordinarily patterned that they are top targets for birdwatchers; and no birder going to Emei Shan, in south China, would want to miss out on the spectacular Grey-cheeked Liocichla or the Gold-fronted Fulvetta. Everyone visiting the Himalayas wants to see a Fire-tailed Myzornis, whether it is a true babbler or not (see Systematics), and one of the best opportunities may be while searching for another spectacular liocichla, the newly described Bugun Liocichla, known only from the Eaglenest Wildlife Sanctuary, in Arunachal Pradesh, a species clearly destined to become a "must-see" for many future bird tours to north-east India. Any bird-

watcher visiting Myanmar and suffering at the end of a hot day in the field could always infuse the black hair-like stalks of a fungus with which the Dark-backed Sibia lines its nest; the local people do so as a cure for headaches.

The genus *Turdoides* has proved to be a highly rewarding set of species in terms of behavioural ecology. The problems posed by group-living, relating to social status, helping at nests and altruistic behaviour, were opened up by the pioneering work of Gaston on Jungle Babblers in India, with answers steadily accumulating and resolving in the remarkable long-term study of Ara-

The **Orange-billed Babbler** occurs from sea-level to 2100 m in Sri Lanka. It inhabits a range of well-vegetated habitats, including broadleaved evergreen forest, thickets, bamboo, secondary forest, and tea plantations.

A restricted-range species confined to the Sri Lanka Endemic Bird Area, it is generally common in the lowlands, especially in the Sinharaja National Heritage Wilderness Area. It is currently listed as Near-threatened in view of the many pressures facing Sri Lanka's forests, including intensive logging and clearance for agriculture and settlements.

[*Turdoides rufescens*, Martin's River Lounge, Kitulgala, Sri Lanka.

Photo: Andy & Gill Swash]

bian Babblers led by Zahavi in Israel, and, in very recent years, studies by A. Radford and Ridley of Southern Pied Babblers in Namibia. Zahavi has elegantly used the example of Arabian Babblers to develop and reinforce his idea of altruism as a "handicap". Status within social groups is crucially important, and Zahavi's theory is that an individual can achieve high rank not only by the sheer strength that makes it the most dominant individual, but also by acts of apparent generosity which signal to others its superior quality, since it is able to survive and continue as a group-member in spite of the disadvantage, the self-imposed handicap, incurred by its seemingly selfless behaviour.

Not only is the White-browed Laughingthrush reputedly a pest in orchards and crops but, improbable as it seems, the Taiwan *Liocichla* has been claimed to be a pest in cultivated pearl-millet, potato, peach and orange crops. These are extremely unusual considerations, however, and it seems very unlikely that either species can do any serious economic damage. Within their habitats, on the other hand, babblers are generally relatively common and therefore fairly important avifaunal components, contributing strongly to the insectivorous guilds of scrub, second growth and the lower storeys of forest, and consequently to the overall health of these habitats and the ecosystems of which they form part.

The origins of some scientific names can prove somewhat surprising. *Leonardina* was established by E. A. Mearns in 1906, after a failed attempt in the preceding year with *Leonardia*, which was preoccupied. The name was in honour of Leonard Wood, a long-standing military colleague and friend of the "super-macho" Theodore Roosevelt. The two men fought together in Cuba, where Wood was governor during 1899–1902, they hiked, rode and wrestled together, and even in the latter's White House years they played "singletick", in which they put on padded helmets, breastplates and gauntlets and then "beat one another like carpets". In 1905–1906, Wood was in charge of military forces on Mindanao, in the Philippines, and gave his support to biological fieldwork undertaken by the Smithsonian Institution, but in March 1906 his troops notoriously killed 600 Moslem Moros, including women and children, holed up in a volcanic crater on the island of Jolo. Mark Twain called it Christian butchery, Roosevelt a "brilliant feat of arms". Mearns's own tribute, albeit the year before this event, was in the name of the humble and retiring Bagobo Babbler (*Leonardina woodi*), one of only two avian species in which the first and last names of a person are used for, respectively, the generic and specific names, the other being the Zapata Wren (*Ferminia cerverei*), named for its discoverer, Fermin Cervera. Wood sought the Republican presidential nomination in 1920, and in the following year became a most unpopular Governor General of the Philippines, a position that he held until his death, in 1927.

Indeed, another genus name based on a figure of some historical notoriety has sometimes been applied to some other Phil-

ippine babblers, although this one, *Borisia*, cannot be used for these birds, as the same name was earlier applied to an insect genus. In any case, the oldest name for this group of babblers as currently constituted is *Sterrhoptilus*. Nonetheless, the case is not without interest, the name *Borisia* having been erected by the Marquess Hachisuka for and "by the gracious permission of His Majesty Boris III, King of the Bulgarians". Boris ruled from 1918 to 1943, when he died prematurely amid rumours of dirty tricks. He had made himself dictator in 1934, a year before Hachisuka's honour, but only reluctantly aligned himself with the axis powers in the Second World War. He had been resisting Hitler's demands to attack Russia when he died, and he had refused to deport the country's 50,000 Jews to Poland, but he did sanction the removal of 13,000 Jews from lands reoccupied by Bulgaria, thus managing at once to be revered and reviled for his actions.

### Status and Conservation

Babblers are not, so far as the great majority is concerned, at serious risk. No species is known certainly to have become extinct, and, remarkably for a family comprising 309 species, only

The **Indochinese Wren-babbler**, previously known as the "Short-tailed Scimitar-babbler" and isolated in the monotypic genus *Jabouilleia*, was formerly considered **Vulnerable**, but was downlisted to **Near-threatened** after healthy populations were found in several protected areas in Laos and Vietnam. It is currently classed as a **restricted-range species**, present in two **Endemic Bird Areas** (Annamese Lowlands and Da Lat Plateau), but its range size needs re-evaluation after the recent discovery of populations in Myanmar.

[*Rimator danjoui parvirostris*, Bach Ma National Park, Central Annam, Vietnam. Photo: James Eaton/Birdtour Asia]

Two *Liocichla* species are listed as **Vulnerable**. The **Grey-cheeked Liocichla** occupies a restricted range in Sichuan and Yunnan, China, while the recently described **Bugun Liocichla** is only known from Arunachal Pradesh, India. Forest species, both are threatened by habitat destruction.

[Left: *Liocichla omeiensis*, China. Photo: Roland Seitre.

Right: *Liocichla bugunorum*, Eaglenest Wildlife Sanctuary, Arunachal Pradesh, India. Photo: Ramana Athreya]

The **Bornean Ground-babbler** inhabits lowland evergreen forest on Borneo. It is listed as Vulnerable, and is perhaps especially threatened by habitat fragmentation because it is an understorey bird, and therefore less likely to disperse through unsuitable habitat. Action is required to control intensive logging, and to halt the rapid clearance of forest to supply paper mills and to make way for oil palm plantations.

[*Ptilocichla leucogrammica*, Bentuang-Karimum National Park, West Kalimantan, Borneo. Photo: Doug Wechsler/VIREO]

one, the recently "split" Blue-crowned Laughingthrush, is classed as Critically Endangered under the IUCN threat-status categorization. Just six more are listed as Endangered: the Flame-templed Babbler; the Negros Striped Babbler (*Zosterornis nigrorum*); the Black-chinned Laughingthrush; the Collared Laughingthrush (*Trochalopteron yersini*); the White-throated Mountain-babbler; and the Grey-crowned Crocias (*Crocias langbianis*). In fact, the conservation status of the Black-chinned Laughingthrush requires reassessment, as the subspecies *jerdoni* has very recently been removed from the Kerala Laughingthrush and placed with the Black-chinned, which was previously monotypic. A further 21 timaliids are placed in the Vulnerable category, with 37 species Near-threatened, and one (herein treated as two species) Data-deficient.

Nevertheless, a few cautionary comments on these figures are needed. Foremost is the consideration that the taxonomy adopted in the present treatment is very new, and BirdLife International, which makes the global assessments, inevitably requires time both to consider the legitimacy of the arrangement and, if accepting it, to undertake the necessary reviews of conservation status. Indeed, following very recent taxonomic "splitting", two of the newly recognized species were added to the threatened list in early 2007. These are the Black-and-white Laughingthrush of

Sumatra, rated as Vulnerable, and the aforementioned Critically Endangered Blue-crowned Laughingthrush of China. A third species, the Bugun Liocichla, was described as new to science as recently as August 2006 and it, too, has now been classed as Vulnerable.

The Blue-crowned Laughingthrush is a great puzzle. It is known from two very restricted sites 1800 km apart in China, at one of which, Simao, in Yunnan, it has not recently been found and at the other of which, Wuyuan, in Jiangxi, it numbers fewer than 200 individuals; yet it has appeared in international trade in the past 20 years, suggesting the possible existence of an undiscovered population. The captive birds are now being carefully managed by a small, dedicated group of zoos and collection-owners. The Black-and-white Laughingthrush, as so many songbirds in Indonesia, suffers from intensive trapping, to the extent that it is an extremely difficult bird to find on the island; indeed, its close relative the White-crested Laughingthrush is now widely imported into Sumatra, presumably as a substitute for the virtually vanished native. Meanwhile, the Bugun Liocichla remains known from just one small area adjacent to Eaglenest Wildlife Sanctuary, in the north-east Indian state of Arunachal Pradesh. The total number of individuals observed here to date is no more than 14, resulting in the decision of the discoverer, R. Athreya, to name the species on the basis of some feathers from and photographs of an individual that was then released. A plan to build a major highway through the single site where the liocichla is known to occur has given rise to considerable alarm among conservationists.

Apart from these, it may be expected that the threat level of several other species will be upgraded. Four timaliids on the current BirdLife list have each now been split into two species, and it seems very likely that the smaller ranges of each, coupled with new information about threats to the habitat, will result in new categorizations. The species involved are the two *Robsonius* babblers, formerly treated as conspecific under the name of "Luzon Wren-babbler"; the two *Sphenocichla* wedge-billed babblers, previously lumped as one; the Mindanao Pygmy Babbler (*Sterrhoptilus plateni*) and Visayan Pygmy Babbler (*Sterrhoptilus pygmaeus*), until recently considered conspecific; and the two *Micromacronus* babblers, formerly combined under the name of "Miniature Tit-babbler". When each of these pairs is treated as a single species, the first three are listed as Near-threatened and the fourth as Data-deficient. Other species as yet not recognized by BirdLife, but which would be likely to be accorded a threatened category, are the Cambodian Laughingthrush, owing to its scarcity within a very limited range; the Orange-breasted Laughingthrush (*Stactocichla annamensis*), Vietnamese Cutia and Black-crowned Fulvetta, for the same reasons; the Taiwan Hwamei, because of its potential interbreeding with escaped Chinese Hwameis; the White-throated (*Rimotor pasquieri*) and Sumatran Wren-babblers (*Rimotor albostratus*), because of their

The **Black-crowned Barwing** was described in 1999 from Ngoc Linh, central Vietnam. Soon afterwards it was found in the highlands of adjacent south Laos. It seems to be restricted to these two areas, where it is scarce and local. Habitat loss and degradation may be causing a decline, and the species is listed as Vulnerable. It will benefit from a conservation project targeting Ngoc Linh Nature Reserve.

[*Actinodura sodangorum*, LoXo Pass, Annam, Vietnam. Photo: James Eaton/Birdtour Asia]

seeming great rarity within poorly understood ranges; and the Naga Wren-babbler, for its tiny range.

The listing of only a proportion of these species as globally threatened would bring the babblers a little more into line with general trends among bird families. At present, Timaliidae has disproportionately few higher-category listings and disproportionately many Near-threatened species, and it will be interesting, therefore, to follow developments in the process of reassessment. One notable and already mentioned feature of the family, its extreme weakness as a cross-water colonist, does, however, mean that it possesses relatively few insular populations, or, at least, relatively few populations on islands small and isolated enough to experience traumas that cause species to decline sharply or to die out. This probably best explains the paucity of Critically Endangered and Endangered species in the current BirdLife assessment.

Even so, there is one species that presents a difficult problem of conservation-status classification, and which is quite possibly extinct and thought by some to be so. The Black-browed Babbler (*Malacocincla perspicillata*) is known from a single specimen collected by C. A. L. M. Schwaner between 1843 and 1848 and sent to the National Museum in Leiden, Holland, where C. L. Bonaparte, the exiled nephew of emperor Napoleon, described it and indicated its provenance as Java. Much later, the Swiss curator of birds at Leiden, J. Büttikofer, realized that the museum had sent Schwaner not to Java, but to southern Borneo, and it was established that he spent much of his time there in the Martapura area of the far south-east. It is, therefore, there that the Black-browed Babbler, which has never been seen again by any eyes that would have known it as such, is believed to have been found. Leiden Museum's website, where the type specimen can be viewed from all angles, states that the species is extinct, owing to its absence from the ornithological record over a period of 160 years and to the horrific deforestation to which all of Kalimantan, especially the lower-lying areas such as in the south-east, has been subjected. On the other hand, BirdLife International, with somewhat misplaced optimism, has treated it as Vulnerable, when in truth the species should be treated as Data-deficient. Searches in Pleihari Martapura are called for.

All six of the Endangered timaliids possess very small ranges, all are birds of forest, and all of their forests, five in Asia and one in Africa, are under pressure. This is more or less the case also for the great majority of the 21 Vulnerable species, 19 of which are in Asia and two in Africa: in all cases, their ranges are slightly larger, though still small, but several of them, the Marsh Babbler,

Jerdon's Babbler and the Slender-billed Babbler, are grassland-dwellers, albeit with the same generic problem of habitat loss. The 37 Near-threatened species, 33 Asian and four African, are barely more diverse, the majority being birds of fairly restricted range and facing a degree of habitat loss, but the number is augmented by the inclusion of a suite of mainly lowland Sundaic forest species for which the 20-year rainforest holocaust in Sumatra and Borneo has been a serious cause of concern, despite their relatively wide ranges. These species include those which, in a review of the effects of fragmentation and logging of forests, were determined as responding unfavourably. Examples are forest-interior terrestrial insectivores such as the Large Wren-babbler and Striped Wren-babbler, and understorey foliage-gleaners such as the Black-throated Babbler, Chestnut-rumped Babbler and Fluffy-backed Tit-babbler.

Trade in wild birds affects many species of babbler, but only five, the Chinese and Taiwan Hwameis (listed as one species), the Silver-eared Mesia, the Red-billed Leiothrix and the Grey-cheeked Liocichla, are listed by CITES, in all cases on Appendix II. The last of these is listed principally in a precautionary role, which is technically not one that CITES is supposed to play and which involves the listing of species which would rapidly become threatened if international trade commenced; nevertheless, it is quite heavily trapped within China, a phenomenon over which, of course, CITES has no control. The Taiwan Hwamei is not heavily traded, but it is listed here because of its former conspecificity with the Chinese Hwamei, which is regarded as one of the finest singers in Asia and is exploited on a massive scale (see Relationship with Man).

The Silver-eared Mesia and the Red-billed Leiothrix are two of the most engaging and attractive of cagebirds, and both have been exploited on a huge scale. Evidence of this comes in CITES official figures, which show that the leiothrix is one of only two passerines, the other being the Hill Myna (*Gracula religiosa*), in the top ten species most commonly present in international trade at the present time. Evidence comes also, however, in the number of feral populations that have become established as a result of breeding and colonization by escapees, including in France, Spain, Germany, the Hawaiian Islands, Japan and the Mascarene Islands. Perhaps the most striking result of trade in babblers is the way in which the avifauna of Hong Kong has

**The Snowy-cheeked Laughingthrush** is a restricted-range species endemic to Sichuan and Gansu provinces, China, and present in the Central Sichuan Mountains Endemic Bird Area.

It occurs in a range of thickets, scrub and stunted forests at high altitudes, between 2000 and 3500 m, and is threatened by the loss and degradation of suitable habitat. It is known from eleven localities, at some of which it is fairly common. However, many areas within its range are inaccessible and poorly surveyed, and it may prove to be more widespread. It is listed as Vulnerable.

[*Ianthocincla sukatschewi*, Wanglang Nature Reserve, Sichuan, China. Photo: John & Jemi Holmes]

**The White-throated Mountain Babbler** occurs in humid montane forests of south-east Nigeria and neighbouring Cameroon. Its overall range is highly restricted, and is estimated at 1990 km<sup>2</sup>. The extent of its preferred habitat continues to shrink, and it is being eroded chiefly by intensive grazing, fire, clearance for agriculture, and exploitation for timber and firewood. The species is classified as Endangered and requires better protection of forests at key sites, including Mount Manenguba, Bakossi Mountains, Rumpi Hills, and Mount Kupé.

[*Kupeornis gilberti*, Bokossi Mountains, Cameroon. Photo: Ketil Knudsen]

**The Grey-crowned Crocias** is a restricted-range species endemic to Vietnam, where it is found only in the humid montane forests of the Da Lat plateau. It disappeared for many years after its discovery but has recently been found at several localities, at one of which it is not uncommon. Its habitat is threatened by forest degradation and fragmentation through logging, shifting agriculture, fuelwood collection and charcoal production, activities which are exacerbated by recent influxes of settlers from other regions. The species is currently classified as *Endangered*.

[*Crocias langbianis*,

been augmented, no fewer than nine species having colonized the territory as a result of accidental escapes of birds in trade. These nine additions are the Streak-breasted Scimitar-babbler, Rufous-capped Babbler, Chinese Babax, Greater Necklaced Laughingthrush, Black-throated Laughingthrush, White-browed Laughingthrush, Blue-winged Siva, Silver-eared Mesia and Red-billed Leiothrix.

The ability of birds to withstand local exploitation for trade is not documented, but it is very crudely the case that babblers are among the commoner elements of avifaunas, sometimes very much the dominant species in numerical terms. Attractive sociable species such as the Black-and-white Laughingthrush are probably the most vulnerable: because they live in groups, all members of which can be caught with great ease by a skilled trapper using a decoy, they can very easily be removed completely from an area by this activity. Moreover, the use by many species of secondary habitats, indeed, their preference for such habitats, means that they are likely to persist even in areas where trapping pressure is considerable. Against this, however, it has to be said that, for many species, detailed data on distribution, density or ecology are lacking, and there is a real challenge to ornithologists to get into the field and provide such data so that the conservation needs of the species in question can be better understood. For example, how many birders, let alone field biologists, have ever seen *Micromacronus*, the single most astonishing discovery among the babblers in the past fifty years and, indeed, of the entire twentieth century? Fewer than five, for sure, in all that time. It is a bird of extraordinary interest, yet we know little more about it than the handful of places where it has been collected.

A fine example of a positive response to a such a need can be found in the research done in the past decade or so on Hinde's Pied Babbler. This species entered the IUCN Red List in 1985, and for a time languished without study. In the mid-1990s, however, work led by P. Njoroge and P. Shaw began to assess its true range, habitat use, breeding success and threats, with the result that its population size can now be stated with moderate confidence and its key habitat requirement is known. Thus, its global population is 1500–5600 individuals, and for high reproductive output it requires more than 10% thicket cover. With these pieces of evidence in place, this rare species is now among

**The Flame-templed Babbler**, a restricted-range species present in the Negros and Panay Endemic Bird Area, is known from five localities on Panay and 18 on Negros, but from only ten sites in total since 1980. It was once thought to be common and widespread, but it seems to be disappearing from many low-lying areas because of habitat destruction and fragmentation. It is listed as *Endangered*. It occupies a monospecific genus on account of its bizarre plumage pattern: a bristly yellow forehead, orange crown plumes, and white ear-covert shafts.

the better-known timaliids, and its conservation can be pursued with vigour.

Nonetheless, global warming, which seems poised to wreak huge damage on most, if not all, bird populations around the world in the coming hundred years, will cast a long shadow of doubt over the future of many species of babbler. In southern California in 2002, the breeding success of the Wrentit, the sole New World member of the family, in semi-arid coastal sage scrub fell to just 3% of its 2001 level, from 2.37 fledglings per pair and 88.4% of adults attempting to breed to just 0.07 fledglings per pair and a mere 6.7% of adults making breeding attempts. The cause was drought, an abnormal circumstance perhaps, but, with an anticipated steady increase in aridity in the region owing to global warming, it may take only one or two more such droughts to eradicate the species altogether from this region.

lower flanks, thighs and vent; iris brown to pale crimson; bill brown, paler base; legs light grey-brown to dark brown. Sexes similar. Juvenile is brown above, with rufous uppertail-coverts and tail. Supercilium ill-defined. Voice: Song, given with throat puffed out, a clear, quickly delivered "phu pwit" (sounding like a human exhaling and then inhaling), sometimes introduced by short "chit" or similar, particularly when excited. When agitated, various combinations of short stuttering notes, e.g. "tu-chit-tu", "tu-chit-tu-chu", "ti-tu" and "tu-chip-tu", may be given before song.

**Habitat.** Grass, thickets near streams, scrubby hillsides, at 1500–3300 m, occasionally to 3700 m.

**Food and Feeding.** Invertebrates. Rather sluggish when foraging, usually in very dense undergrowth 2–3 m above ground. Will sit up in the open.

**Breeding.** Jun–Jul. Nest described as a cup made of leaves, twigs and bark, lined with wool and grass, placed 0.3 m above ground in small tree. Clutch 3 eggs, white with uneven reddish-brown, purple-brown and light brown dots, denser around broader end. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common. A relatively poorly known species.

**Bibliography.** Cheng Tsohsin (1976, 1987), Cheng Tsohsin *et al.* (1963), David & Oustalet (1877), Hornbuckle (2003), Li Guiyuan, Liu Liangcai *et al.* (1976), Li Guiyuan, Zhang Qingmao & Wen Anxiang (1993), Meyer de Schauensee (1984), Riley (1926), Stresemann (1923c), Tan Yaokuang & Cheng Tsohsin (1964), Vaurie (1954b), Yang Youtao & Zhang Tao (1997).

## Genus CHAMAEA Gambel, 1847

### 6. Wrentit

#### *Chamaea fasciata*

French: Cama brune

German: Chaparraltimalie

Spanish: Camea

**Taxonomy.** *Parus fasciatus* Gambel, 1845, Monterey, Monterey County, California, USA. Additional proposed races include *intermedia* (from interior and S areas of San Francisco Bay region of California), synonymized with *rufula*, and *canicauda* (from NW Baja California), treated as a synonym of *henshawii*. Five subspecies recognized.

**Subspecies and Distribution.**

*C. f. phaea* Osgood, 1899 – extreme W USA from W Oregon (R Columbia) S along humid coastal belt to California border.

*C. f. margra* Browning, 1992 – interior S Oregon.

*C. f. rufula* Ridgway, 1903 – NW California coast from Oregon border S to San Francisco Bay area.

*C. f. fasciata* (Gambel, 1845) – coastal C California (from W Monterey County S to C San Luis Obispo County).

*C. f. henshawii* Ridgway, 1882 – interior and coastal S California, and extreme NW Mexico (NW Baja California).

**Descriptive notes.** 14–16 cm; 14–15 g. Small greyish-brown babbler with vague pinkish tinge below, long and rounded tail. Nominate race has crown greyish mid-brown with vague darker streaks, shading slightly paler (less grey) and plainer on nape and upperparts, including upperwing and tail; lores pale buffy grey, rest of face plain grey-brown; chin and submoustachial area pale buffy grey with darker flecks, shading below to dull greyish salmon-pink with vague darker streaking, apart from greyer neck side and slightly brown-tinged flanks and lower belly, thighs and vent; iris whitish; bill horn to blackish-brown; legs blackish. Sexes

similar. Juvenile is like adult. Races differ mainly in depth of plumage coloration: *phaea* is darkest, with brownest underparts; *rufula* is paler than previous, clearer rich brown above, paler vinaceous cinnamon below, flanks washed rufous-brown; *margra* is dark brown, flanks tinged pale pinkish-brown; *henshawii* is palest and greyest, greyish-brown above, greyish-buff below. Voice. Song of male, usually from cover but sometimes from exposed perch, a series of loud, rather dry notes on one pitch and speeding into trill at end, c. 3–4 seconds in duration, "yip-yip-yip-yip-yip-yip-yip-yip-tr-tr-tr-tr-tr-r-r-r-r-r" ("bouncing-ball song"), given throughout year but with greater frequency Mar–Jul, never very intensively, so that possibly as few as four bouts of song per hour (each bout with 3–6 songs), even at dawn in spring. Female sings a series of similar notes at constant rate of 2–3 per second, and with no trill; also throughout year, mostly from within cover. Sexes often answer one another when separated. Both sexes also give slower series of notes which are doubled, "weeka, weeka, weeka". Other calls are a scolding, rasping purr, often in groups of 3–5, for contact, a louder rasping and much-repeated "krrrr" in alarm, a soft mewling "mye-ah" when approaching young, a soft "peep" and low "chuck" when in group moving through vegetation. Bill-snapping heard in interspecific combat, and wing-whirring in distraction display near nest.

**Habitat.** Dense brushy and shrubby areas as are found in many habitats, including douglas fir (*Pseudotsuga*) and redwood (*Sequoia sempervirens*) forest, early successional growth, mature riparian valleys oak (*Quercus lobata*), oak woodland, mixed hardwood, conifer and conifer stands (reaching peak abundance in older forests), riparian deciduous scrub (e.g. willows (*Salix*), dense thickets of coyote bush (*Baccharis*) and blackberry (*Rubus*), and suburban areas, may occur in more open woodland with few shrubs. Highest densities in coastal sage scrub, northern coastal scrub and montane chaparral. In coastal Oregon, prefers dense huckleberry (*Vaccinium*) and salal (*Gaultheria shallon*); in Central Valley of California ideal habitat blackberry tangles and California grape (*Vitis californica*); in foothills and desert regions uses chamise (*Adenostoma fasciculatum*), California lilac (*Ceanothus*), manzanita (*Arctostaphylos*), scrubby oaks and even mesquite (*Prosopis*). Sea-level to 2300 m.

**Food and Feeding.** Insects, including caterpillars, butterflies and moths and their cocoons (Lepidoptera), beetles (Coleoptera), bees (Hymenoptera), ants (Formicidae), small wasps (Hymenoptera), scale insects (Coccoidea); also spiders (Araneae) and centipedes (Chilopoda), latter sometimes subdued by use of both feet. Also fruits and seeds, including those of elderberry (*Sambucus*), snowberry (*Symphoricarpos albus*), coffeeberry (*Rhamnus californica*), twinberry (*Lonicera imrayana*), blackberry, and laurel samac (*Rhus laurifolia*), seeds of poison oak (*Toxicodendron diversilobum*) especially important, offering seven-month winter food supply. Will eat various scraps at bird-feeders. Invertebrate food 52% and vegetable food 48% over whole year, but annual matter

up to 96% in spring, 36% in autumn. Nestlings in coastal California provided mainly with green larvae of geometrid moths ("inchworms"). Forages mainly by gleaning items from woody parts of plants, less commonly from leaves, petioles and fruiting stems. Will briefly hover, e.g. at sticky monkey flowers (*Mimulus*), and flycatch. Commonly forages in pairs or family parties, individuals close together. Will drink from standing water, but more commonly from wet surfaces of plants, but little dependence on water.

**Breeding.** Season Mar–Aug, start of breeding apparently timed in response to climatic conditions and to cues predicting conditions later in season: sometimes double-brooded (20% of pairs) if first brood raised relatively early in season. Monogamous, more than 95% of individuals mating for life; usually remains on territory if partner dies. Solitary, but record of two active nests only 4 m apart. Nest built by both sexes, in c. 6–7 days (range 3–14 days), a deep compact cup made of fibres, bark and spider web, lined with fine stems, outer wall sometimes plastered with lichen, placed usually 0.3–1.5 m above ground among twigs of shrubs; in coastal scrub in California mean nest height 0.75 m, mean height of vegetation 1.5 m, in riparian habitat mean nest height 1.7 m, mean height of vegetation 3.6 m; territory 0.24–2.15 ha (average 0.62 ha), generally smaller in denser than in sparser scrub. Clutch 3 or 4 eggs, rarely 2 or 5, pale greenish-blue; incubation by both sexes, period 14–15.5 days; nestling period 11–19 days (average 15 days); young stay in family party for 18–41 days (typically, 30 days) after fledging; as early as 30 days of age may form lasting pair-bond with older individual, staying on territory until next breeding season 11 months later. Nests parasitized rarely by Brown-headed Cowbird (*Molothrus ater*). Mean annual probability of nest fledging at least one young 45% at one site; eggs and nestlings preyed on by Western Scrub-jay (*Aphelocoma californica*), garter snake (*Thamnophis*) and gopher snake (*Pituophis*), and pair builds up to five nests in season in effort to rear single brood; c. 16% of pairs successful at fledging two broods, and these produced significantly more young per season than did pairs attempting only one brood; mean lifetime breeding success expressed as total young fledged 4.3 (range 0–31), expressed as total young successfully recruited to breeding population 0.45 (range 0–3). First breeding at 1 year in 70% of cases, sometimes 2 years (16%) or 3 years (7%); mean age at first nest attempt 1.5 years. Average longevity from ringing studies 3.3 years, males living longer than females; adult annual survival of known breeders 64% for males, 59% for females; juvenile survival to recruitment 21.9%.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Abundant in cismontane shrublands, especially coastal scrub and chaparral. Range may be expanding to E & NE with deforestation, resulting in more shrubby cover. Density of breeding adults positively correlated with previous winter's rainfall and with breeding success in previous spring. Population seemingly regulated by availability of scrub and chaparral-type habitat; proximity of urban areas and reduction in size of suitable patches are linked to local reduction in abundance and local extinction. Low-level, prescribed burning appears to improve shrub diversity and cover complexity, and is associated with subsequent increases in nesting success.

## Genus LIOPARUS Oates, 1889

### 7. Golden-breasted Fulvetta

#### *Lioparus chrysotis*

French: Fulveta à poitrine dorée

German: Goldalceippe

Spanish: Fulveta Dorada

Other common names: (Himalayan) Golden-breasted Tit-babbler

**Taxonomy.** *Pr[oparus]. chrysotis* Blyth, 1845, no locality = Nepal.

Genus commonly merged with *Alcippe*. Birds reported from C Yunnan (N Ailao Shan), in S China, have not been assigned to race. Six subspecies recognized.

**Subspecies and Distribution.**

*L. c. chrysotis* (Blyth, 1845) – C Nepal E to NE India (W Arunachal Pradesh) and adjacent S China (SE Xizang).

*L. c. albilineatus* Koelz, 1954 – NE India (S Assam, Nagaland, Manipur).

*L. c. forresti* Rothschild, 1926 – NE Myanmar and S China (NW Yunnan).

*L. c. swinhoei* (J. Verreaux, 1870) – S China from SE Gansu, S Shaanxi and C Sichuan S to Guangxi, SE Hunan and N Guangdong.

*L. c. amoensis* (Mayr, 1941) – S China (SE Yunnan) and NW Vietnam (W Tonkin).

*L. c. rohsoti* (J. C. Eames, 2002) – C Vietnam (C Annam).

**Descriptive notes.** 10–11.5 cm; 5–10 g. Colourful fulveta, blackish-grey above with silvery ear-coverts and orange-yellow underparts. Wing flashes and outer tail. Male nominate race has lores, forehead, crown and supercilium blackish, with paler bluish-grey in vague line (variable in intensity) down centre; nape bluish-grey, but more blackish at side; upperparts bluish-grey, more olive-tinged on back, rump and uppertail-coverts, latter more yellow-olive and tipped paler; uppertail blackish, each feather having orange-yellow outer fringe on basal two-thirds; upperwing-coverts blackish, tertials blackish with broad white inner fringes. Flight-feathers blackish on inner vanes but outer vanes of inner primaries yellow and those of outer secondary orange-yellow (forming double wing flash), ear-coverts silvery-grey with darker shaft, chin and upper submoustachial area blackish-grey, becoming bluish-grey on lower throat and behind ear-coverts; underparts bright orange-tinged yellow, deeper based at sides breast and flanks, very hazel to brown, bill pale bluish-pinkish, with upper mandible orange-banded. Sexes dissimilar, coloured to dull orange. Female is like male but may be paler orange-yellow. Young of *forresti* has throat yellow. Race *albilineatus* has conspicuous white median crownstripe and richer

**Food and Feeding.** No information on diet; presumably small invertebrates and some vegetable matter. Found in pairs or small parties, often in association with other species, including other babblers, in mixed flocks.

**Breeding.** Occupies breeding elevations May–Sept in Bhutan. No further information.

**Movements.** Resident; some clear seasonal altitudinal displacements, at least in Bhutan.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in Eastern Himalayas EBA. Uncommon in E Bhutan; locally fairly common in India, where present in and/or near Eaglenest Wildlife Sanctuary (Arunachal Pradesh). Fairly common in SE Xizang (China).

**Bibliography.** Ali & Ripley (1972), Cheng Tsohsin (1987), Choudhury (2003), Grimmett *et al.* (1998), Katti *et al.* (1992), Ludlow (1951), Ludlow & Kinnear (1937, 1944), Rasmussen & Anderton (2005), Ripley *et al.* (1991), Robson (1986), Singh (1995), Spierenburg (2005), Stattersfield *et al.* (1998), Yen Kwokying (1936).

## 10. Grey-hooded Fulvetta

### *Fulvetta cinereiceps*

**French:** Fulvetta à gorge rayée **German:** Braunkopfalcippe **Spanish:** Fulveta Encapuchada  
**Other common names:** Brown-headed Tit-babbler; Chestnut-backed Fulvetta (*fucata*); Fujian Fulvetta (*guttaticollis*)

**Taxonomy.** *Siva cinereiceps* J. Verreaux, 1870, “les montagnes du Thibet chinois” = Muping [Paohing], south-east Xizang, China.

Genus commonly merged with *Alcippe*. Formerly treated as conspecific with *F. manipurens* and *F. formosana*, but these exhibit considerable differences. Races *fucata* and *guttaticollis* may represent two additional species; further study required. Four subspecies recognized.

**Subspecies and Distribution.**

*F. c. fessa* Bangs & J. L. Peters, 1928 C China (S Ningxia S to S Gansu, S Shaanxi and extreme N Sichuan).

*F. c. cinereiceps* (J. Verreaux, 1870) – NE, C & S Sichuan S to W Guizhou (SC China).

*F. c. fucata* (Styan, 1899) – W Hubei S to N Guizhou, NE Guangxi and SE Hunan (E China).

*F. c. guttaticollis* (La Touche, 1897) – SE China from NW Fujian S to N Guangdong.

**Descriptive notes.** 12 cm. Small brownish, plain-headed and nondescript Fulvetta with ochre, black and whitish in wing. Nominative race has crown and mantle pale soft greyish, slightly darker, browner lores and vague supercilium or lateral crownstripe, shading to mid-brown back and ochreous-rufescent rump, upperside-coverts, outer webs of secondaries and outer fringes of tail; wing and tail otherwise mid-brown, former with blackish and greyish-white wingpanel; side of face and neck a shade paler and vaguely pinker than crown; chin, throat, breast, mid-belly and thighs greyish-white, breast with vestigial streaking,

flanks and vent ochreous-tan; iris pale straw, pinkish-yellow, yellowish-brown or brown; bill black to dark brown, or light brown; legs dark brown to greyish-brown or brownish-flesh. Sexes similar. Juvenile is presumably as adult. Race *fessa* is very like nominate, but slightly less reddish, more olivaceous, above; *guttaticollis* has pale vinous-brown crown, very vague smoky-brown lateral crownstreaks, black outer vane of secondaries, and more obvious but still indistinct pale grey streaking on breast; *fucata* is like last, but crown richer brown, back chestnut-brown, breast streaking barely apparent. Voice. Song (nominative race) a loud, high, thin, breathless, whistled “ti fuu fiuu” or “ti wuu wiiuu” (first note rising, second slightly descending, third rising and then falling), repeated every 5–7 seconds. Calls with sibilant, thin, quavering churring rattle.

**Habitat.** Undergrowth and bamboo in broadleaf forest, spruce, fir and maple forest, secondary growth, scrub, brambles and bamboo; 1400–3400 m (mostly above 1700 m) in summer, locally as low as 1000 m in winter.

**Food and Feeding.** Insects, caterpillars, and small molluscs. Forages actively and with agility, in manner of a tit (Paridae).

**Breeding.** Season Apr–Jun. Nest a neat cup, strongly woven from bits of leaf skeleton, leaves, grasses and moss, lined with tendrils, placed in fork of low bush or dwarf bamboo. Clutch 4 or 5 eggs, pale greenish to bluish-green with brownish-green spots and blotches over brown, lilac and grey undermarkings. No other information.

**Movements.** Resident; reportedly a winter visitor to Guangdong, but this improbable.

**Status and Conservation.** Not assessed. Common and widespread in S China, although in one survey recently recorded only in Maershan Nature Reserve (Guangxi) and not in 53 other sites visited; is, however, present at Emei Shan Protected Scenic Area and Wa Shan and in Jiuzhaigou and Wolong Nature Reserves, all in Sichuan.

**Bibliography.** Bangs & Peters (1928), Caldwell & Caldwell (1931), Cheng Tsohsin (1987), Cheng Tsohsin *et al.* (1993), Collar (2006), Deditius (1897), Dowell *et al.* (1997), Huang Qiang, Deng Heli & Mao Ke (1995), Huang Yan (1988), King (1989b), La Touche (1899, 1925–1930), Lee Kwok Shing *et al.* (2006), Li Guiyuan, Liu Liangcai *et al.* (1976), Li Guiyuan, Zhang Qingmao *et al.* (1994), Meyer de Schauensee (1984), Ripley (1952), Ripley *et al.* (1991), Smythies (1986), Stanford & Ticehurst (1935, 1938), Stresemann (1923c), Vaurie (1954b), Wang Zhijun (1983), Wang Zhijun & Wei Tianhao (1983), Wu Zhikang *et al.* (1986), Yen Kwokying (1936), Yu Zhiwei *et al.* (1986), Zhang Quntan *et al.* (1994), Zheng Baolai (1988), Zheng Zuoxin & Qian Yanwen (1973), Zheng Zuoxin *et al.* (1987).

## 11. Streak-throated Fulvetta

### *Fulvetta manipurens*

**French:** Fulvetta du Manipur **German:** Streifenkehlalcippe **Spanish:** Fulveta de Manipur  
**Other common names:** Manipur Fulvetta

**Taxonomy.** *Proparus manipurens* Ogilvie-Grant, 1906, Owenkulno Peak, Manipur, India. Genus commonly merged with *Alcippe*. Formerly treated as conspecific with *F. cinereiceps* and *F. formosana*. Two subspecies recognized.

**Subspecies and Distribution.**

*F. m. manipurens* (Ogilvie-Grant, 1906) – NE India (E Arunachal Pradesh S to S Assam and N Manipur), W & N Myanmar and S China (W Yunnan).

*F. m. tonkinensis* (Delacour & Jabouille, 1930) – S China (SE Yunnan) and N Vietnam (W Tonkin).

**Descriptive notes.** 11–12 cm. Small. Nominative race has greyish, mantle and back pinkish-milky brown, buff-headed, buff-throated, lateral crownstreaks becoming narrow broad streaks, rump, lower back and rump pale rufous; tail milky brown, upperside similar but with pale rufous fringes and

of inner primaries, paler bill. Sexes similar. Juvenile apparently resembles adult. Race *tonkinensis* has darker lateral crownstreaks, slightly more contrasting pattern of throat streaks, and slightly richer rust colour on lower underparts. Voice. Song a rather well-spaced, very high-pitched “ti ti si su”; transcribed also as a simple, sibilant, high-pitched “si-swu” or “see, si-wu”, the “si” note(s) clear and the last note burr, as “si-seé-swú”, all notes thin and sibilant, and as “si-si-suu-swéé”, the last note more stressed, prolonged, slurred, and with greater bandwidth than the others. Calls include low “tirru” notes when on the move, also high, thin, sibilant “swi-swi-swi-swi...”, and thin, dry, metallic “twit-it-it-it-it-it-it...” or harder, more spluttering rattled version.

**Habitat.** Broadleaf evergreen forest, forest edge, bamboo and scrub; at 1400–2500 m in India, 1525–2800 m in SE Asia.

**Food and Feeding.** Mainly small insects and their eggs, caterpillars, tiny snails, some vegetable matter. Found in parties of 6–10 individuals outside breeding season, often associating with mixed flocks which may contain other small babblers. Forages quite close to, and sometimes on, ground; sometimes ascends in trees.

**Breeding.** Apparently from Apr in India. Nest a well-built, strongly woven, small cup made of leaf skeletons, bamboo and other leaves, and grasses, bound with moss, lined with tendrils or soft shiny black fibres, placed in fork of low bush or dwarf bamboo. Clutch 3–5 eggs, 4 or 5 in India, pale greenish or sea-green, blotched and spotted with brownish over underlying violet, lilac and grey clouds and some short brown hair-lines. No other information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Generally scarce to rare. Found very sparingly in survey of E Arunachal Pradesh (India) in spring 1990. Locally common in China and Vietnam; present in Fan Si Pan National Park, in Vietnam.

**Bibliography.** Ali & Ripley (1972), Cheng Tsohsin (1987), Choudhury (2003), Collar (2006), Delacour & Jabouille (1930, 1931a), Grimmett *et al.* (1998), Katti *et al.* (1992), Meyer de Schauensee (1984), Rasmussen & Anderton (2005), Robson (2000), Singh (1995), Smythies (1949), Stanford (1935, 1941), Stanford & May (1941), Tordoff, Lê Manh Hùng *et al.* (2002), Tordoff, Lê Trong Dat *et al.* (2001), Yen Kwokying (1936).

## 12. Taiwan Fulvetta

### *Fulvetta formosana*

**French:** Fulvetta de Taiwan **German:** Taiwanalcippe **Spanish:** Fulveta de Formosa

**Taxonomy.** *Proparus formosanus* Ogilvie-Grant, 1906, Mount Morrison, central Taiwan.

Genus commonly merged with *Alcippe*. Formerly treated as conspecific with *F. cinereiceps* and *F. manipurens*. Monotypic.

**Distribution.** Taiwan.

**Descriptive notes.** 12 cm; mean 10 g. Has crown to back milky grey-brown, soft-edged but broad mid-brown lateral crownstreaks continuing onto mantle; lower back and rump pale rufous, upperside and tail grey-brown with pale rufous fringing, rufous forming strong panel on secondaries above narrow black wingpanel (inner primaries) and narrow whitish panel (outer primaries); lores to eye grey sooty grey, eyering whitish, cheek and ear coverts grey-brown; chin to breast whitish with soft-edged but rather broad milky-brown streaks, shading to plain pinkish grey-brown on belly and upper flanks, rufous-tinged olive-brown lower flanks to vent; iris pale golden-brown; bill pale pinkish-grey to pale brown; legs pale brown. Differs from similar *F. manipurens* in having black lores, white eyering, more extensive and pronounced throat and breast streaking, much weaker lateral crownstripe, more olive lower belly and flanks, stronger rufous wingpanel, and pink-tinged throat. Sexes similar.

Juvenile apparently resembles adult. Voice. Song “ti tuuu”, first note rising, second descending, typically repeated every 3–6 seconds, of similar quality to song of *F. manipurens*. Calls squeaky contact call a thin high “shiiip...shiiip” or “tsee-tsee”.

**Habitat.** Undergrowth and bamboo understorey of coniferous forest, underbrush of deciduous forest and adjacent open low montane vegetation, at 2130–2400 m, breeding mainly in alpine bamboo and pinewood undergrowth; elevational limits in N Taiwan 1590–3000 m.

**Food and Feeding.** Insects and seeds found in stomachs. Forages in pairs or small groups, on or just above the ground; sometimes rather mouse-like.

**Breeding.** May–Jul. Clutch 2 eggs. No further information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Fairly common to common. In Yushan National Park, recorded densities of 1.99 birds/ha in grassland, 9.15/ha in pine woodland, 9.42/ha in mixed coniferous woodland and 3.19/ha in spruce forest.

**Bibliography.** Collar (2006), Collar (2004, 2006), Collar *et al.* (2004), Ding Lianmei *et al.* (2004), Hamaoka & Udagawa (1950, 1951), Koh (haonien & Lee Peifen (2003), Meyer de Schauensee (1984), Severinghaus & Blackshaw (1976), Yang Xiusing (1991), Yen Chungwei (1990), Yen Kwokying (1936).

## 13. Chinese Fulvetta

### *Fulvetta striaticollis*

**French:** Fulvetta montagnarde **German:** Bergalcippe **Spanish:** Fulveta China  
**Other common names:** Streak-throated Tit-babbler

**Taxonomy.** *Siva striatocollis* J. Verreaux, 1870, "les montagnes du Thibet chinois" = Muping [Paohing], south-east Xizang, China.  
Genus commonly merged with *Alcippe*. Monotypic.

**Distribution.** S China: S Gansu S to SE & E Xizang, extreme NW Yunnan and W & C Sichuan.

**Descriptive notes.** 11.5 cm. Relatively drab small fulvetta, brown above, whitish below, with streaks on throat and breast. Crown and nape are buffish-tinged or biscuit-tinged mid-brown, feathers of forehead and crown with faint brown streaks (and forehead looking slightly grey-tinged from certain angles); long brown lateral crownstripe from above eye across upper mantle, most prominent on side of nape and upper mantle; rest of upperparts and tail like crown, with tertials, secondaries and upperwing-coverts warm brown on outer vanes, primaries showing narrow grey wing-panel between pale brown outer feathers and

brown inner feathers; lores dark brown, slightly greyish vague supercilium from above eye to above rear ear-coverts, ear-coverts as crown but streaked pale greyish or buffy; chin, submoustachial area, throat and upper breast off-white with brownish streaks, rest of underparts pale greyish-white, lower flanks and undertail-coverts mixed with light brown; iris white to cream-yellow or lemon-yellow; upper mandible horn-brown to dark horn-brown, lower mandible paler to fleshy-pink; legs horn-brown to fleshy-brown or livid. Sexes similar. Juvenile is darker above and duller below than adult. Voice. Song a simple "ti tsew" or "tsi chuu", first note rising, second one falling. Calls with short low rattles, "trrrt-t", "chrrr-r'r't" and the like, sometimes continuously.

**Habitat.** Shrubbery, rhododendron, and prickly oak (*Quercus ilex*), at 2200–4300 m; 2775–4265 m in summer in Xizang.

**Food and Feeding.** No information on diet; presumably small invertebrates and some vegetable matter. Forages in pairs or small groups, low down in vegetation.

**Breeding.** Season Jun–Jul in Xizang, Jul–Aug in rest of range. Nest made of grass, covered with moss and lichen on outside, lined with hair, suspended from branch of bamboo. Clutch 4 eggs. Nests preyed on by yellow-bellied weasel (*Mustela kathiah*). No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Locally common; present in Jiuzhaigou Nature Reserve, in N Sichuan.

**Bibliography.** Ali & Ripley (1972), Bangs & Peters (1928), Cheng Tsohsin (1987), King (1989c), King & Peng Jilai (1991), Lee Thehhow *et al.* (1965), Li Guiyuan *et al.* (1976), Ludlow (1951), Ludlow & Kinnear (1944), Meyer de Schauensee (1984), Rasmussen & Anderton (2005), Robson (1986), Schäfer & Meyer de Schauensee (1938), Sien Yaohua *et al.* (1964), Stresemann (1923c), Weigold (1925), Yen Kwokying (1936).

## 14. Spectacled Fulvetta

### *Fulvetta ruficapilla*

**French:** Fulvetta de Verreaux **German:** Rotscheitelalcipe **Spanish:** Fulveta de Verreaux

**Taxonomy.** *Siva ruficapilla* J. Verreaux, 1870, "les montagnes du Thibet chinois" = western Sichuan, China.

Genus commonly merged with *Alcippe*. Formerly treated as conspecific with *F. danisi*. Birds recorded in S China (Yunnan and Guizhou) probably belong in present species on basis of range, but not yet compared with type of *F. danisi*. Two subspecies recognized.

**Subspecies and Distribution.**

*F. r. ruficapilla* (J. Verreaux, 1870) – C China (S Gansu and S Shaanxi S to SC & NE Sichuan).

*F. r. sordidior* (Rippon, 1903) – S China (W & C Yunnan E to SW Sichuan and W Guizhou).

**Descriptive notes.** 10.5–11 cm; 8–10 g. Small, soft-coloured fulvetta. Nominat race has forehead mid-grey, shading to dull vinous-rufous on crown, becoming pinkish-grey on nape, neck side and mantle, and warm ochrous-brown on back, rump and uppertail-coverts; outer fringes of upperwing-coverts, tertials, secondaries and outer tail rufous-ochre, upperwing and tail plain mid-brown, primaries showing narrow grey wing-panel between pale brown outer feathers and brown inner feathers; lores blackish, this colour running up in front of eye to become narrow dark lateral crownstripe, bordered below by increasingly

broad pale grey supercilium; submoustachial area, area below eye and ear-coverts pale vinous-

pinkish; throat whitish with mid-greyish streaks extending onto upper breast; upper flanks and across breast pale pinkish-grey, middle belly whitish, lower flanks and vent rufous-ochre; iris dark brown, whitish eyering broken at rear; bill grey-brown, lower mandible paler; legs dark brown. Sexes similar. Juvenile presumably resembles adult. Race *sordidior* has crown a little less reddish, ear-coverts a little paler, lateral crownstripes broader, blacker and longer (extending to rear of nape), mid-belly tinged buff, lower flanks and undertail-coverts paler and buffier, less rufous. Voice. No information available.

**Habitat.** Broadleaf evergreen oak forest, dense secondary scrub-jungle and brambles, at 1250–2500 m, occasionally to 2800 m. Published statements of occurrence at elevations to 4000 m considered unreliable.

**Food and Feeding.** Invertebrates, including grubs, scaly-winged insects; also seeds. Found singly or in pairs, also in parties of up to ten or more individuals. Forages low down or in canopy of small trees.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Uncommon to locally common; range appears to be considerable.

**Bibliography.** Bangs & Peters (1928), Cheng Tsohsin (1987), Collar (2006), Deditius (1897), La Touche (1923), Meyer de Schauensee (1984), Riley (1926), Stresemann (1923c), Tan Yaokuang & Cheng Tsohsin (1964), Vaurie (1954b), Wang Zhijun & Wei Tianhao (1983), Wu Zhikang *et al.* (1986), Yen Kwokying (1936), Zheng Baolai (1988), Zheng Zuoxin & Qian Yanwen (1973).

## 15. Indo-Chinese Fulvetta

### *Fulvetta danisi*

**French:** Fulvetta de Danis **German:** Streifenwangenalcipe **Spanish:** Fulveta Indochina

**Taxonomy.** *Alcippe (Fulvetta) ruficapilla danisi* Delacour & Greenway, 1941, Phu Kobo [19°16' N, 103°25' E], Laos.

Genus commonly merged with *Alcippe*. Until recently treated as conspecific with *F. ruficapilla*. Birds of S China (Yunnan and Guizhou) provisionally placed in race *sordidior* of *F. ruficapilla* on basis of range, but not yet compared with type of present species. Two subspecies recognized.

**Subspecies and Distribution.**

*F. d. danisi* (Delacour & Greenway, 1941) – NE & EC Laos.

*F. d. bidoupensis* (J. C. Eames *et al.*, 1995) – SE Laos and C Vietnam (C & S Annam).

**Descriptive notes.** 11.5 cm; 9–13 g. Nominat race has crown to mantle greyish-brown, long blackish-brown lateral crownstripe; back and rump to uppertail rufous-brown, upperwing rufous-brown, outer primaries with greyish-white fringes forming narrow wing-panel; lores and supercilium whitish, cheek and ear-coverts tan; chin to upper breast pinkish-buff with vague tan streaks, lower breast pinkish-buff, shading to white on belly and to rufous on flanks and vent; bare-part colours of nominat undescribed, for race *bidoupensis* iris medium to dark brown, bill fleshy-horn to dark horn, usually with more flesh-coloured base, legs dark greyish-flesh to dark horn. Differs from similar *F. ruficapilla* mainly in having crown darker and greyer, wings plainer, throat and upper breast pinkish-buff with darker streaks. Sexes similar. Juvenile undescribed. Race *bidoupensis* has browner crown than nominat, no whitish fringes on primaries (wing-panel entirely absent). Voice. Song undocumented; possible song (singer unseen) transcribed as "see-sew-see-see". Calls with quickly repeated, rapid "chrrrrit" and "chrrt-chrrt-chrrt...".

**Habitat.** Bamboo, undergrowth and understorey, sometimes also canopy, in broadleaf evergreen forest and secondary scrub in cleared areas, oak and rhododendron forest, shrubs in clearings and along forest edge; in Laos low-stature upper montane forest. Elevation limits 1800–2440 m.

**Food and Feeding.** No information on diet; presumably small invertebrates and some vegetable matter. Found singly, in pairs or in small parties of up to eight individuals. Race *bidoupensis* seen in single-species flocks.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Locally common within relatively small range. In Laos, present in Nakai-Nam Theun National Biodiversity Conservation Area and very common in Xe Sap proposed protected area. In Vietnam, present in Thuong Da Nhim and Chu Yang Sin Nature Reserves (Da Lat Plateau, in S Annam), and in Vu Quang Nature Reserve.

**Bibliography.** Cheng Tsohsin (1987), Collar (2006), David-Beaulieu (1944), Delacour & Greenway (1941), Eames (1995), Eames, Eve & Tordoff (2001), Eames, Robson & Nguyễn Cu (1994), Evans & Timmins (1998), Meyer de Schauensee (1984), Robson (2000), Thewlis *et al.* (1998), Wu Zhikang *et al.* (1986).

# Genus *YUHINA* Hodgson, 1836

## 16. Taiwan Yuhina

### *Yuhina brunneiceps*

**French:** Yuhina de Taiwan **German:** Braunkopfyuhina **Spanish:** Yuhina de Formosa  
**Other common names:** Formosan Yuhina

**Taxonomy.** *Yuhina brunneiceps* Ogilvie-Grant, 1906, Mount Morrison, central Taiwan. Monotypic.  
**Distribution.** Taiwan.

**Descriptive notes.** 11.5 cm; mean 12 g. Distinctive yuhina with dull brown crest with black lateral crownstripe, olive-brown upperparts and whitish underparts, and thin, rather long bill. Forehead and erectile crown feathers are dull chestnut-brown, some underlying feathers whitish (visible when crest raised), distinct black lateral crownstripe from bill base to hindcrown; nape and upperparts greyish olive-brown, upperwing and tail mid-brown with paler buffy-whitish fringes; head side (lores, increasingly broad supercilium, area under eye, ear-coverts) whitish, narrow black eyestripe from behind eye and looping around lower edge of ear-coverts and cheek to form broken submoustachial stripe; whitish below, washed grey on breast side and upper flanks, with narrow blackish shaft streaks on lower throat and breast, long but irregular and variable brown streaks on lower flanks, thighs olive-brown; iris red to dull red; bill black; legs yellowish-brown to yellowish. Sexes similar. Juvenile is apparently as adult. **Voice.** Song a jaunty, mellow, sweet "too, mee, jeeoo" ("to meet you", sometimes "so pleased to meet you"), last note a descending slur.

**Habitat.** Deciduous and evergreen broadleaf forest, mixed broadleaf and coniferous forest, sometimes spruce, fir and cedar forest, also forest edge and clearings, at 1200–2400 m in summer, some descending to 1000 m or lower in winter; in N Taiwan, elevational limits 805–2780 m. In one study in fragmented habitat during breeding period, preferred woods, open spaces and orchards in that order, but within home ranges preferred orchards to open spaces, and cherry trees (*Prunus*) appeared to be selected as food resource.

**Food and Feeding.** Nectar of cherry blossoms and other flowers reported; doubtless also small invertebrates and probably small fruit. Found in stable small parties typically of 3–7 adults (most commonly four) throughout year. Forages in lower strata to canopy. Very mobile, and will cross large open areas.

**Breeding.** Apr–Jun; up to three broods per season (span of brood cycle from nest-building to independence of young 70 days). Has habit of communal nesting, three or four pairs may lay in one nest and incubate eggs in turn. Pair socially monogamous, but in one study 20% offspring were sired by a male from another group and 20% by another male from within group; inter-group cuckoldry affected 6 out of 12 nests and intra-group cuckoldry affected 8 out of 12 nests. Large groups have larger home ranges. Nest built by both sexes in group, but with more input from females, a small deep cup, made of roots, bits of fern, moss and cobweb, lined with fern leaves, placed among thick branches of *Arundinaria* bamboo. Clutch 2–3 eggs, pale greenish-blue, marked all over with small greenish or buffish-brown freckles over underlying grey freckles; incubation period 14 days; nestling period 12 days. Maximum recorded longevity 12 years; c. 24–30% of birds at one site disappeared annually (through emigration or mortality); estimate of average adult annual overwinter survival 74%.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Taiwan FBA. Common to abundant in C highlands, commonest at middle elevations. In Yushan National Park, recorded densities of 1–12 birds/ha in grassland, 2–48/ha in pine woodland, 8–84/ha in mixed coniferous forest and 2–03/ha in spruce forest (none of these being optimal habitat for the species).

**Bibliography.** Cheng Tsohsin (1987), Ding Tzungsu *et al.* (1997), Ebert (1986), Fang Wei-hong (2005), Hachisuka & Udagawa (1950, 1951), Hung Hsiyi (2003), Koh Chaonien & Lee Peifen (2003), Kraus (1985), Lee Peifen *et al.* (2005), Liu (1999), Meyer de Schauensee (1984), Ogilvie-Grant (1906), Severinghaus & Blackshaw (1976), Shen Shengfeng (2002), Smith & Yu Hontsen (1992), Stattersfield *et al.* (1998), Yamashina (1938), Yen Chungwei (1990), Yu Hontsen & Lin Liang-kong (1985), Yuan Hsiaowei, Liu & Shen Shengfeng (2004), Yuan Hsiaowei, Shen Shengfeng & Hung Hsiyi (2006), Yuan Hsiaowei, Shen Shengfeng, Lin Kai-ying & Lee Peifen (2005).

## 17. Black-chinned Yuhina

### *Yuhina nigripenta*

**French:** Yuhina à menton noir **German:** Meisenyuhina **Spanish:** Yuhina Barbinegra  
**Other common names:** Pale Yuhina

**Taxonomy.** *Yuhina nigripenta* Blyth, 1845, Nepal.

Geographical variation clinal, with slight increase in size and underpart pallor from E to W. Proposed races *intermedia* (from NE Myanmar and C & S China S to N Laos and S Vietnam) and *pallida* (highlands of Fujian, in SE China) appear to represent middle stage and end, respectively, of this cline. Treated as monotypic.

**Distribution.** From N India (E from Kumaon, in Uttaranchal Pradesh) E to all NE hill states and N & W Myanmar, adjacent SE Xizang (Zayu), C, S & SE China (N & NE Sichuan, E Jiangxi, S Zhejiang, NW Fujian, Yunnan, Guangxi), N & C Laos, Vietnam (Tonkin, N & S Annam) and extreme E Cambodia.

**Descriptive notes.** 9–10 cm; 8–14 g. Smallest yuhina, dull greenish grey-brown above and buff below, with blackish face and crest on dull grey head, narrow red bill. Has crown mid-grey, slightly

brown-tinged, with broad blackish centres, feathers slightly elongate (forming low crest); upperparts, upperwing and tail drab greenish grey-brown, washed greyer on mantle and warmer on rump; lores to above eye, upper submoustachial area and chin black, ear-coverts and supercilium plain grey like nape, throat white with slight buffy tinge; underparts dirty buff, richer on lower flanks and vent, with breast side, upper flanks and thighs washed mid-brown; iris hazel or brown to dark crimson; upper mandible horn-brown to black with reddish base, lower mandible orange-red, coral-red or vermillion; legs yellowish-brown or orange-flesh. Sexes similar. Juvenile has upperparts and edges of wing and tail browner, crest shorter. **Voice.** Song remarkable, a clear thin high-pitched sequence of short sibilant ringing whistles, "uu ii uui ii uui uu ii uui uu ii uui...", with higher "ii" notes; other versions include "seet, suet, seet, seet...", in no set pattern, and an even-tempo sequence of very short thin even-pitched notes, "sit-sit-sit-sit...". Calls include a subdued, light, musical staccato chattering and titting (heard continuously from flocks), occasionally becoming a louder nervous harsh "whit'rr'u", "wh'rr'r" and "whrr'rr'ik"; also a near-continuous metallic "pik! pik! pik!..." mixed with other notes.

**Habitat.** Broadleaf evergreen forest, second growth, and overgrown clearings. Mostly at 350–1825 m in India, sometimes down to 100 m in Assam, and recorded at 2500 m at Eaglenest Wildlife Sanctuary; 610–1500 m in Nepal; 400–2000 m, occasionally down to 300 m and up to 2300 m (once 2800 m), in Bhutan; 300–2300 m in China, but 1650–1700 m in SE Xizang; 200–2135 m in SE Asia.

**Food and Feeding.** Insects and their larvae (including millers, moth pupae), berries, seeds (including those of grass), rice, and flower nectar; ingests some grit, including quartz. In Aug–Mar, outside breeding season, found in parties of 5–20 individuals, often in association with mixed flocks. Forages in canopy and low bushes, sometimes in undergrowth or in tall grass under trees.

**Breeding.** Mar–Jul in Indian Subcontinent, May–Jul in Myanmar, Apr–Jun in China (Jul in SE Xizang), and Jan–Feb in Laos; probably multi-brooded, in Bhutan three periods of singing (with reduced flock sizes), in Apr, May and Jul, suggesting highly synchronized breeding (pair with young in Aug). Nest, constructed over at least 3 days, a beautiful compact cradle or basket made of moss and moss roots or other fibrous material, lined with very fine grass stems, rootlets and fibres (including coir), either suspended from moss or lichen hanging from underside of branch within 2 m of ground, or fastened to exposed hanging roots on bank or attached to eaves of bamboo-thatched shed or coir-wrapped base of palm branch or even tea plant. Clutch 3–6 eggs, usually 4 in Indian Subcontinent, 3–4 in Myanmar, 4–6 in China, pale sea-green with profuse very pale brown or reddish freckles, or (Indian Subcontinent) occasionally pale clay or clay-green with spots numerous but smaller, or (S China) sparingly and delicately speckled light brown over underlying markings of reddish-grey, violet or lavender; incubation by both sexes, period 12–13 days; nestling period 13–15 days.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to scarce in Nepal. Common throughout temperate zone and foothills in Bhutan, but scarcer in W; present in Thrumshingla National Park. Generally fairly common locally in India, where rare in Dehra Dun valley (Uttaranchal), present in Buxa Tiger Reserve (West Bengal), and in Eaglenest Wildlife Sanctuary and Namdapha and Mouling National Parks (all Arunachal Pradesh), and rare in Khushi Hills (Assam). Uncommon to scarce resident in SE Bangladesh. Scarce in NE & W Myanmar. In China, locally common in SE, and recently recorded at six of 54 sites surveyed in S, including Diding Nature Reserve (Guangxi), where rare; common in mountains in NW Fujian. Locally common across SE Asian range: present in proposed extension to Nakai-Nam Theun National Biodiversity Conservation Area, in Laos; in Vietnam, common in Tam Dao National Park and present in Na Hang Nature Reserve (E Tonkin), and in Thuong Da Nhim and Chu Yang Sin Nature Reserves (Da Lat Plateau, in S Annam), also in Pu Mat and Vu Quang Nature Reserves (N Annam).

**Bibliography.** Ali & Ripley (1948, 1971), Allen *et al.* (1997), Baars (1981), Beils (1956), Birand & Pawar (2004), Caldwell & Caldwell (1931), Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paolai (1960), Cheng Tsohsin *et al.* (1963), Choudhury (2003), David-Beaulieu (1944), Delacour (1929), Delacour & Jabouille (1931a), Dowell *et al.* (1997), Duckworth & Hedges (1998), Eames (1995), Eames *et al.* (2001), Evans & Timmins (1998), Grimmett *et al.* (1998), Hill (2000), Huang Qiang, Deng Heli & Mao Ke (1995), Huang Qiang, Huang Yongzhao & Deng Heli (1993), Inskipp & Inskipp (1991), Inskipp *et al.* (2000), Katti *et al.* (1992), King (1989a, 1989b), Koel (1954), La Touche (1925, 1930), Lê Manh Hùng *et al.* (2002), Lee Kwok Shing *et al.* (2006), Lewthwaite (1996), Li Dehao *et al.* (1978), Li Guiyuan *et al.* (1994), Liu Kezhi *et al.* (1994), Ludlow & Kinnear (1944), Meyer de Schauensee (1984), Obernauer (1977, 1978), Painter (1965), Rasmussen & Anderton (2005), Ripley (1952), Robbins *et al.* (2006), Robson (2000), Robson *et al.* (1989), Showler, Davidson, Khounmee Salivong & Khamkhoun Khounboline (1998), Singh, A.P. ## 18. White-collared Yuhina

### *Yuhina diademata*

**French:** Yuhina à diadème **German:** Diademyuhina **Spanish:** Yuhina Diademada

**Taxonomy.** *Yuhina diademata* J. Verreaux, 1869, "le Thibet oriental" = Muping (Paohing), south-east Xizang, China.

Two subspecies recognized.

**Subspecies and Distribution.**

*Y. d. diademata* J. Verreaux, 1869 – C China (S Gansu and Hubei S to Sichuan and Guizhou).

*Y. d. anpelina* Rippon, 1900 – NE Myanmar E to S China (Yunnan) and N Vietnam (Tonkin).

**Descriptive notes.** 14–18 cm, 15–20 g. Relatively large, long-tailed greenish-brown yuhina with dark crest, prominent white nuchal collar and white underwing-coverts, shallowly forked tail. Nomi-

On following pages: 19. Stripe-throated Yuhina (*Yuhina gutaris*); 20. Rufous-vented Yuhina (*Yuhina occipitalis*); 21. White-naped Yuhina (*Yuhina bakeri*); 22. Whiskered Yuhina (*Yuhina flavicollis*); 23. Burmese Yuhina (*Yuhina humilis*); 24. Striated Yuhina (*Staphida castaneiceps*); 25. Chestnut-collared Yuhina (*Staphida torquata*); 26. Chestnut-crested Yuhina (*Staphida everetti*); 27. Flame-templed Babbler (*Dasyeratapha speciosa*); 28. Mindanao Pygmy Babbler (*Sterrhophilus plateni*); 29. Visayan Pygmy Babbler (*Sterrhophilus pygmaeus*); 30. Golden-crowned Babbler (*Sterrhophilus dennistouni*); 31. Black-crowned Babbler (*Sterrhophilus nigrocapitatus*); 32. Rusty-crowned Babbler (*Sterrhophilus capitalis*).

coverts white; iris chestnut to dark brown, white orbital ring broken at front and rear; bill dusky yellow or yellowish with brown culmen; legs yellowish to dusky yellow or orange-yellow. Sexes similar. Juvenile is like adult. Race *ampelina* is darker, more greyish-brown, than nominate. Voice. Calls include subdued, worrisome "wi wrrr" i wrrr wrrr".

**Habitat.** Open broadleaf evergreen forest, secondary growth, and tea plantations; at 800–3600 m in China, 1250–2745 m in SE Asia.

**Food and Feeding.** Insects, including beetles (Coleoptera); also small seeds, rhododendron nectar. Forages in pairs or in small groups.

**Breeding.** Apr–May in Myanmar and May–Sept in China. Nest a flimsy, almost transparent cup made of dry leaves, dry grass and black roots, well plastered with cobweb or moss and roots, lined with rootlets, palm fibre, grass, stalks and strands from parasitic plants, placed low down (0.2–1.5 m above ground) in bush, brambles, wild raspberry, bracken, coarse grass or small tree. Clutch 2–3 eggs, usually 2 in Myanmar, whitish, pale green or greenish-blue, profusely blotched and speckled with amber, brown and bluish-purple or light brown, blackish and purple; incubation by both sexes, mostly by female. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. In China, common at Emei Shan Protected Scenic Area (Sichuan) and very common in S, where present in Cenwanglaoshan Nature Reserve (Guangxi), with daily counts of up to ten individuals. Locally fairly common in Myanmar; fairly common in Fan Si Pan National Park, in Vietnam.

**Bibliography.** Bösche (2005), Cheng Tsohsin (1987), Cheng Tsohsin *et al.* (1963), Deditius (1897), Delacour & Jabouille (1930, 1931a), Dowell *et al.* (1997), Harington (1909, 1914a), Huang Qiang *et al.* (1995), King (1989a, 1989b, 1989c), La Touche (1923), Lee Kwok Shing *et al.* (2006), Li Guiyuan *et al.* (1993), Liu Kezhi *et al.* (1994), Meyer de Schauensee (1984), Riley (1926), Robson (2000), Rothschild (1926), Smythies (1986), Stanford (1941), Stanford & Mayr (1941), Stanford & Ticehurst (1938), Stresemann (1923c), Tan Yaokuang & Cheng Tsohsin (1964), Traylor (1967), Wang Zhijun & Wei Tianhao (1983), Wu Zhikang, Lin Qiwei *et al.* (1986), Wu Zhikang, Yang Jiongli & Xu Weishu (1981), Zheng Zuoxin & Qian Yanwen (1973).

## 19. Stripe-throated Yuhina

### *Yuhina gularis*

**French:** Yuhina à gorge striée **German:** Kehlstreifenyuhina **Spanish:** Yuhina Goliestriada  
**Other common names:** Eastern Stripe-throated Yuhina

**Taxonomy.** *Yuhina gularis* Hodgson, 1836, Nepal.

Four subspecies recognized.

**Subspecies and Distribution.**

*Y. g. vivax* Koelz, 1954 – N India (Uttaranchal Pradesh).

*Y. g. gularis* Hodgson, 1836 – Nepal, Bhutan, NE India (Arunachal Pradesh, Nagaland, Manipur), S & SE Xizang, W, N & E Myanmar, S China (W, C & S Yunnan), N Laos and N Vietnam (W Tonkin).

*Y. g. omeiensis* Riley, 1930 – C & S China (W, C & N Sichuan S to N & NE Yunnan).

*Y. g. uthaii* J. C. Eames, 2002 – C Vietnam (C Annam).

panel); lores dusky, with blackish band to above eye, head side including supercilium medium brownish-grey; submoustachial area dirty pinkish-buff, chin and throat similar and with regular lines of dark brown streaks and malar line; underparts dirty ochre-buff; iris dark reddish-brown to pale brown; upper mandible dark brown, lower mandible basally brownish-yellow to fleshy-pink; distally dark brown; legs yellow to brownish-flesh or fleshy orange. Sexes similar. Juvenile is slightly darker rufous-brown above, especially on uppertail-coverts, crest shorter. Race *vivax* is paler than nominate, particularly on throat and breast; *omeiensis* is very like nominate, but with greyish-pink breast and upper belly; *uthaii* has whiter throat with much broader streaks. Voice. Typically calls with loud, short, descending, very nasal "mherr" or "wherr" or "skyeer" notes, often in long series and sometimes followed by hurried "whu'whu'whu'whi'whi'whi" (possibly song), sometimes alternated with clearer, quick, upslurred "squik!". Also, short "wiht" notes and a more abrupt descending "squip".

**Habitat.** Temperate oak, birch and rhododendron forest or mixed rhododendron and coniferous forest, occasionally low scrub and bamboo. In Indian Subcontinent, breeds at 2135–3700 m, some descending to 1700 m (rarely 1160 m) in winter, but in Bhutan summer range 2400–3400 m (occasionally to 3600 m) and keeps within this range in winter but also shifting lower (to 1600 m, occasionally 800 m). In China mainly 1200–3050 m, down to 1100 m on Emei Shan; breeds to 3800 m in Xizang. In SE Asia 1675–3200 m.

**Food and Feeding.** Beetles (Coleoptera), wasps (Hymenoptera) and other insects; also berries (e.g. of *Hepiapterum*), flower nectar (of various rhododendrons, *Prunus*, *Magnolia*) and seeds (of *Prunus*, *Magnolia*, etc.); in Feb, also takes sugar-rich sap from bark. Usually found in small par-

ties, often in association with mixed feeding flocks which may contain other small babblers, notably *Y. occipitalis* in period Jan–Apr. Forages in taller bushes and lower branches of trees, sometimes low down. Behaviour somewhat like that of a tit (Paridae), but slower. Regularly visits rhododendron blossoms for nectar.

**Breeding.** May–Jun in India, Jul–Aug in Bhutan, Apr–May in SE Xizang and Mar–Jun in SE Asia. Nest a large, rough ball or dome with side entrance, made of well-interlaced moss, fern and roots, lined with finer roots, placed in branch fork of bush, palm crown, bamboo clump, or between ledges of rocks. Clutch 4 eggs, dingy grey-green or pale green, profusely but not boldly speckled with reddish-brown. No other information.

**Movements.** Resident; some altitudinal descent in winter, most such records after Jan, thereafter moving gradually upslope in time with season of rhododendron flowering.

**Status and Conservation.** Not globally threatened. Common and widespread in Nepal, including in Langtang National Park. Abundant in Bhutan; one of commonest bird species in high-elevation forests, and present in Thrumshingla National Park. In India, although apparently uncommon resident in Garhwal and Mussooree (Uttar Pradesh), common in Himalayas E to Arunachal Pradesh and S to Nagaland and Manipur, and present in Buxa Tiger Reserve (West Bengal) and in and/or near Eaglenest Wildlife Sanctuary (Arunachal Pradesh). Common in Natmantaung National Park, in W Myanmar. Common in China. Generally common in SE Asian range.

**Bibliography.** Ali & Ripley (1972), Allen *et al.* (1997), Betts (1956), Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paolai (1960), Cheng Tsohsin *et al.* (1963), Choudhury (2003), David-Beaulieu (1944), Delacour & Jabouille (1931a), Dowell *et al.* (1997), Eames (2002), Grimmett *et al.* (1998), Hopwood & Mackenzie (1917), Huang Qiang *et al.* (1995), Inskipp & Inskipp (1991), Inskipp *et al.* (2000), Katti *et al.* (1992), King (1989a, 1989b), Kinnear (1929, 1934), Koelz (1954), Li Guiyuan *et al.* (1976), Ludlow (1951), Ludlow & Kinnear (1937, 1944), Martens & Eck (1995), Meyer de Schauensee (1984), Oates (1883), Rasmussen & Anderton (2005), Riley (1926), Ripley (1952), Robson (1986, 2000), Singh (1995), Smythies (1986), Spierenburg (2005), Stanford (1935, 1941), Stanford & Mayr (1941), Stanford & Ticehurst (1938), Stevens (1923), Stresemann (1923c), Stresemann & Heinrich (1940a), Thet Zaw Naing (2003), Tordoff, Lê Manh Hùng *et al.* (2002), Tordoff, Lê Trong Dat *et al.* (2001), Tymstra (1993), Wang Zhijun & Wei Tianhao (1983), Zheng Zuoxin *et al.* (1983).

## 20. Rufous-vented Yuhina

### *Yuhina occipitalis*

**French:** Yuhina à ventre roux **German:** Rotsteifyuhina **Spanish:** Yuhina Ventrirrufa  
**Other common names:** Slaty-headed Yuhina

**Taxonomy.** *Yuhina Occipitalis* [sic] Hodgson, 1836, Nepal.

Two subspecies recognized.

**Subspecies and Distribution.**

*Y. o. occipitalis* Hodgson, 1836 – C & E Nepal and Bhutan E to NE India (Arunachal Pradesh) and adjacent SW China (S & SE Xizang).

*Y. o. obscurior* Rothschild, 1921 – N Myanmar and S China (NW & C Yunnan, SW Sichuan).

**Descriptive notes.** 12–14 cm; 10–16 g. Fairly large greyish-brown yuhina with rufous nape and vent, prominent crest, slightly forked tail. Nominative race has side of forehead pale rufous-buff, forehead with blackish tips, elongate and erectile crown feathers rather dark greyish-brown, central rear crown with slightly greyer tips, those at side broadly tipped rufous-chestnut; upper nape rufous-chestnut, lower nape mid-grey, mantle and back mid-brown with vague pinkish tinge, rump and uppertail-coverts paler, drab olive-brown; tail dark brown, outer fringes paler; upperwing dark brown, but outer fringes of upperwing-coverts,

tertiaries and secondaries slightly warm-tinged mid-brown, primary coverts slightly darker than upperparts; lores dusky, ear-coverts pale pinkish-grey with whitish shaft streaks, rather broken submoustachial streak blackish; chin, throat, breast and area behind ear-coverts pale vinous-pinkish, central belly warm buff, lower belly, thighs and undertail-coverts rufous-tan; iris brown, white orbital ring; bill reddish-brown, reddish-grey or pinkish; legs yellow to dull reddish-brown. Sexes similar. Juvenile has shorter crest than adult, rufous on nape paler, less vinaceous on breast. Race *obscurior* is duller and greyer than nominate, ear-coverts slightly darker and with more contrasting shaft streaks. Voice. Song a simple, weak, rather high-pitched "swi'si'su'su swi'si'si'si'si'su'su...". Calls with short, hard, bouncy, nasal, buzzy notes, "bee", "beebee" and "bzee, bzee-bzeee...", somewhat variable in pitch and duration, repeated irregularly and in chorus.

**Habitat.** Broadleaf evergreen forest, particularly oak–rhododendron forest. In Indian Subcontinent and Xizang, at 2250–3630 m (sometimes to 3900 m) in summer, some descending to 1830 m (occasionally to 500 m) in winter; mainly 3050–3400 m in summer in Nepal; main range in Bhutan 2400–3400 m, occasionally to 3800 m, but in winter down to 1600 m or lower, rarely 400 m. Recorded at 1830–2500 m, locally down to 800 m in winter, in Myanmar. In S China occurs at 1800–3700 m, some descending to 1350 m in winter.

**Food and Feeding.** Mostly insects in summer. Partial to visiting rhododendron blossoms in search of nectar and probably insects; berries eaten in winter, in Feb also sugar-rich sap from bark. In Oct to late Apr, outside breeding season, found in parties of up to 15 (larger flocks generally only in Dec), often associating with mixed feeding flocks which may contain other small babblers such as minlas, fulvettas and yuhinas; associates especially with *Y. gularis*, with which it feeds on flowering trees as they progressively bloom upslope. Forages in high foliage, on moss-covered trunks and branches and in bushes.

**Breeding.** Apr–Jun in Indian Subcontinent. One nest a cup of moss and leaves, lined with fine roots, built into large lump of moss (which formed dome over nest), 1 m up in fork of small tree, another a shallow cup among streamers of black lichen hanging from drooping downswep tips of conifer branch, 4–5 m above ground. Clutch 2 or more eggs. No other information.

**Movements.** Resident; some altitudinal displacement to lower levels in winter.

**Status and Conservation.** Not globally threatened. Common in Nepal, including in Langtang National Park. Common in Bhutan, and present in Thrumshingla National Park. In India, locally fairly common to common from Sikkim E to Arunachal Pradesh, and present in Buxa Tiger Reserve (West Bengal) and in Eaglenest Wildlife Sanctuary and Mouling National Park (both Arunachal Pradesh). Common in Myanmar and China.

**Bibliography.** Ali & Ripley (1972), Allen *et al.* (1997), Birand & Pawar (2004), Cheng Tsohsin (1987), Choudhury (2003), Grimmett *et al.* (1998), Inskipp & Inskipp (1991), Inskipp *et al.* (2000), Katti *et al.* (1992), King (1989a), Ludlow (1951), Ludlow & Kinnear (1937, 1944), Martens & Eck (1995), Meyer de Schauensee (1984), Rasmussen & Anderton (2005), Riley (1926), Robson (2000), Singh (1995), Smythies (1940, 1949), Spierenburg (2005), Stanford

& Mayr (1941), Stevens (1923), Tan Yaokuang & Cheng Tsohsin (1964), Tymstra (1993), Wang Zhijun & Wei Tianhao (1983), Zheng Zuoxin *et al.* (1983).

## 21. White-naped Yuhina

### *Yuhina bakeri*

**French:** Yuhina à nuque blanche **German:** Rotkopfyuhina **Spanish:** Yuhina Nuquiblanca  
**Other common names:** Baker's/Chestnut-headed Yuhina

**Taxonomy.** *Yuhina bakeri* Rothschild, 1926, Darjeeling, West Bengal, India. Monotypic.

**Distribution.** E Nepal E to Bhutan, NE India (Arunachal Pradesh S to N Cachar, in S Assam) and N Myanmar, and adjacent parts of China (SE Xizang, NW Yunnan).

**Descriptive notes.** 12–13.5 cm; 14–24 g. Relatively stout-billed yuhina with rufescent-brown head, white nape and throat, silvery-streaked ear-coverts, strong crest. Crown, lower nape, neck side and mantle are dull rufous-brown, feathers of crown elongate and erectile, upper nape broadly white-tipped; upperparts drab mid-brown with dark greyish-olive cast, upperwing and tail browner; lores blackish-brown, ear-coverts plain rufous-brown with broad silvery-whitish streaks, area under eye as crown, submoustachial as crown with whitish flecks; chin and throat whitish with very vague dark marks, merging to slightly pinkish-tinged buff

with vague long dark streaks on breast, flanks drab buffish-olive, central belly whitish, lower belly, thighs and undertail-coverts yellowish-tan; iris reddish-brown to yellowish-brown; bill dark brown to black; legs dull olivaceous to brown. Sexes similar. Juvenile has mantle browner, underparts paler with streaks less distinct. **Voice.** Possible song a hurried series of high thin notes repeated every 1–3 seconds, "tsu tsu tsu" or "du du du", "tsu tsu", and "tsu tsu tsu", etc. Calls include very thin, piercing, high-pitched, short, metallic notes, e.g. "tsit", "sit-sit (...)", "tsu" and "tsit", also a slightly falling "seep"; also "seet-chuut", second note harsh and much lower, reminiscent of common note of *Y. flavicollis* but much less guttural.

**Habitat.** Primary and secondary broadleaf evergreen forest, at 300–2200 m.

**Food and Feeding.** Insects and berries. Found in parties of 5–10 individuals, sometimes 30, outside breeding season; sometimes in association with mixed feeding flocks (with e.g. *Y. flavicollis* and *Alcippe nipalensis*), but forms single-species flocks up to 20. Forages in treetops and bushes.

**Breeding.** Apr–Jul. Nest, built by both sexes, a cup-shaped or dome-shaped structure of moss mixed with dead leaves, roots and bits of bracken, lined with fine rootlets, placed low down in bush, in hollow in bank or against moss-covered tree trunk. Clutch 3–4 eggs, usually 4, white with blotches varying from reddish-brown to deep umber-brown; incubation by both sexes. No other information.

**Movements.** Resident; some seasonal altitudinal displacement.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Eastern Himalayas EBA. Very rare and local in SE Nepal. Bhutan probably holds important population, as it contains large areas of intact forest within this species' elevational range, some within protected areas (where highest numbers recorded), and near Zhemgang density of 0.6 pairs/km of road noted at 1600–1900 m; present in Thrumshingla National Park. Locally fairly common in India E from Sikkim, being present in Buxa Tiger Reserve (West Bengal), and reported as being commonest member of this genus in Mouling National Park, and present in and/or near Eaglenest Wildlife Sanctuary and in Namdapha National Park (all in Arunachal Pradesh); locally common in Nagaland, where seen traded in Kohima market. Uncommon in Myanmar. Locally fairly common within restricted range in China.

**Bibliography.** Ali & Ripley (1948, 1971), Allen *et al.* (1997), Birand & Pawar (2004), Cheng Tsohsin (1987), Choudhury (2001, 2003, 2005), Grimmer *et al.* (1998), Inskipp & Inskipp (1991), Inskipp *et al.* (2000), Katti *et al.* (1992), Koelz (1954), Meyer de Schauensee (1984), Rasmussen & Anderton (2005), Ripley (1961), Robson (2000), Singh (1995), Smythies (1949, 1986), Spierenburg (2005), Stanford & Mayr (1941), Stattersfield *et al.* (1998), Stevens (1914, 1923), Stuart Baker (1893), Tymstra (1993), Zheng Zuoxin *et al.* (1983).

## 22. Whiskered Yuhina

### *Yuhina flavicollis*

**French:** Yuhina à cou roux **German:** Gelbnackenyuhina **Spanish:** Yuhina Bigotuda  
**Other common names:** Yellow-naped Yuhina

**Taxonomy.** *Yuhina? flavicollis* Hodgson, 1836, central Nepal.

May form a superspecies with *Y. humilis*, and until recently considered conspecific. Five subspecies recognized.

**Subspecies and Distribution.**

*Y. f. albicollis* (Tiechurst & Whistler, 1924) – N India (Himachal Pradesh) E to W Nepal.

*Y. f. flavicollis* Hodgson, 1836 – C Nepal E to NE India (Arunachal Pradesh) and adjacent S China (SE Xizang).

*Y. f. rouxi* (Dustalet, 1896) – NE India (SE Arunachal Pradesh S to hill states S of R Brahmaputra), W, N & E Myanmar, S China (Yunnan), NW Thailand, N Laos and N Vietnam (Tonkin).

*Y. f. rogersi* Deignan, 1937 – E part of NW Thailand.

*Y. f. constantiae* Ripley, 1953 – NC & C Laos.

**Descriptive notes.** 12–12.5 cm; 10–19 g. Mid-sized yuhina with grey head and crest, golden-yellow hindcollar, black moustache and yellowish-white underside. Nominative race has elongate and erectile crown feathers brown, lateral feathers behind eye, including supercilium, pale greyish-brown, upper nape pale brownish-grey, lower nape and neck side rufous, shading to golden-yellow on hindneck, and fading into yellowish-grey-tinged olive-brown on upperparts; upperwing and tail darker brown; lores blackish-brown, this colour rising over eye and linking below with blackish-brown submoustachial stripe (broken near bill base); ear-coverts slightly glossy silvery brown; chin and throat white with narrow brown shaft streaks, breast washed yellow (fades on museum specimens) with narrow brown shaft streaks, belly washed yellow, breast side and flanks dull buffish olive-brown with long white streaks; vent as flanks but without streaks; iris red-brown to dark brown; prominent broad white orbital ring broken at front and rear, upper mandible horn-brown to dark brown, lower mandible flesh or pinkish-brown to dusky greyish; legs yellowish to fleshy brown; sexes similar. Juvenile lacks streaking below, and colour of nuchal collar indistinct. Race

repeated, shrill, high-pitched "tzii-jhu ziddi", with stressed first note and slightly undulating end note; also as "two-tyurwi-tyawi-tyawa". Calls include thin squeaky "swii swii-swii" and sudden harsh buzzy nasal "jhoh", this sometimes preceded by thin high note, "fzee-tzzip".

**Habitat.** Bush layer and lower storeys of montane broadleaf evergreen forest, oak and open deciduous forest, and secondary growth. In India 1435–1980 m (occasionally to 3000 m) in summer (above 1000 m in Assam), some descending in winter to 500 m and occasionally to edge of plains; in Nepal 1830–2750 m in summer, down to 800 m in winter; in Bhutan 1600–2800 m (occasionally to 3200 m in summer), some descending to 1000 m and even 600 m in winter. In Myanmar 1065–2620 m in summer, some descending to 215 m in winter; 1200–2440 m in Thailand and Indochina, and in C Laos found mainly above 1800 m in upper montane forest but sometimes lower in *Fokienia*-dominated forest. Mainly 1500–3050 m in China, but 2135–2285 m in summer in Xizang.

**Food and Feeding.** Insects and their larvae (including aquatic insects), small snails (including pond snails); also flower nectar, berries (of *Rubus*, including yellow raspberries and yellow blackberries, also *Galium*, *Trema*, etc.) and small seeds (of *Michelia cathartica* and others); feeds on insects parasitic on *Ziziphus*; in Feb takes sugar-rich sap from bark. In Aug–Mar, outside breeding season, found in small parties of 5–10 individuals, sometimes in association with mixed feeding flocks which may include other small babblers. Forages in lower branches of trees and bushes, sometimes low brambles. Behaviour rather like that of a tit (Paridae).

**Breeding.** Apr–Jun. Nest, built by both sexes, a well-made cup mostly of moss, with rootlets, bits of leaves and bracken, thickly lined with rootlets and moss roots, suspended between twigs, or placed among moss on branch, or on bank among roots or tufts of grass, up to 2 m (rarely 4 m) above ground. Clutch 2–4 eggs, white with numerous pink spots; incubation by both sexes, for 13–14 days; young provisioned by both sexes, no information on duration of nestling period.

**Movements.** Resident, with some altitudinal descent in winter; alleged to be a winter immigrant in Nagaland (NE India), but this seems unlikely.

**Status and Conservation.** Not globally threatened. Commonest yuhina in Himalayas, but owing to low elevations rare in Dehra Dun valley and uncommon in Corbett National Park (Uttaranchal), in India; locally common in W Himalayas from Himachal Pradesh E to W Nepal, common in C & E Nepal including Langtang National Park, and E to NE India. In Bhutan abundant, and one of commonest bird species in broadleaf forest in temperate zone; near Zhemgang density of 2.3 breeding pairs/km of road noted at 1600–1900 m; present in Thrumshingla National Park. In E Indian Himalayas present in Buxa Tiger Reserve (West Bengal) and in Eaglenest Wildlife Sanctuary, Namdapha National Park and Mouling National Park (all Arunachal Pradesh). In Myanmar, common in Natmautaung National Park and fairly common elsewhere in country. Common in China. Generally common in SE Asian range: locally common in NW Thailand; present in Phou Dendin National Biodiversity Conservation Area (NBCA) and common in Nakai-Nam Theun, in Laos; present in three protected areas in the Annamese Lowlands Endemic Bird Area, in Vietnam.

**Bibliography.** Ali & Ripley (1948, 1971), Allen *et al.* (1997), Bangs (1921), Bingham (1903), Birand & Pawar (2004), Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paolai (1960), Choudhury (2001, 2003), Collar (2006), David-Beaulieu (1944), Davidson (1998), Deignan (1963), Delacour & Jabouille (1931a), Eames *et al.* (2001), Evans & Timmins (1998), Gaston (1989), Gaston *et al.* (1994), Grimmer *et al.* (1998), Harington (1909), Hopwood & Mackenzie (1917), Inskipp & Inskipp (1991), Inskipp *et al.* (2000), Katti *et al.* (1992), Kinnear (1929), La Touche (1923), Lê Manh Hùng *et al.* (2002), Lekagul & Round (1991), Löffing (1984), Ludlow (1951), Ludlow & Kinnear (1944), Martens & Eck (1995), Meyer de Schauensee (1984), Rasmussen & Anderton (2005), Ripley (1952, 1961), Robson (1986, 2000), Rothschild (1926), Round (1999), Schurzinger (1985), Singh, A.P. ## 23. Burmese Yuhina

### *Yuhina humilis*

**French:** Yuhina de Birmanie **German:** Graunackenyuhina **Spanish:** Yuhina Birmana

**Taxonomy.** *Ixulus humilis* Hume, 1877, Mulayit Taung (16°11' N, 98°32' E), Tenasserim, Myanmar. May form a superspecies with *Y. flavicollis*, and until recently considered conspecific. Two subspecies recognized.

**Subspecies and Distribution.**

*Y. h. clarki* (Oates, 1894) – E Myanmar.

*Y. h. humilis* (Hume, 1877) – S Myanmar (N Tenasserim) and W Thailand.

**Descriptive notes.** 12–12.5 cm. Nominative race has crown slightly milky warm mid-brown, nape milky grey-brown, medium-grey neck side and hindcollar, upperparts, upperwing and tail soft warm ochre-tinged brown, head side as crown, but darker on arcs and moustachial line, whitish below, with tiny dark shaft streaks from chin to breast, long pale grey-brown streaks on flanks, and brown-tinged whitish thighs and vent; iris reddish-brown, prominent broad white orbital ring broken at front and rear; upper mandible blackish-brown, lower mandible pale brown; legs fleshy-brown. Differs from *Y. flavicollis* in having browner crown and ear-coverts (crown barely darker than upperparts), soft mid-grey hindcollar, whitish upperparts, faint streaking on chin and throat, and white-centred grey flank feathers. Sexes similar. Juvenile is presumably as adult. Race *clarki* differs from nominate in having forehead, crown and

crest rich umber-brown, rest of plumage ashy, with larger and more conspicuous silvery patch on neck side. *Yuhina* not adequately described. Flock-members utter low "chir-chir", occasionally "chir-chir-chir-chir"; also repeated "chit-a-wit" when alarmed.

**Habitat.** Montane broadleaf evergreen forest, pine and oak forest, at 1075–2275 m.

**Food and Feeding.** Fruit, nectar and insects, last two taken at blossoms of small trees. Found in pairs or small parties.

**Breeding.** Apr in Myanmar and Feb in Thailand. One nest was a "sling" of moss c. 40 cm long, sewn along a twig c. 15 m above ground, with barely noticeable entrance about half-way down; visited by parents alternately, roughly every two minutes.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in (and responsible for defining) Myanmar–Thailand Mountains Secondary Area. Generally uncommon to locally common; scarce to uncommon in Umphang area of W Thailand, and present in Mae Ping National Park and adjacent Mae Tuen and Om Koi Wildlife Sanctuaries. Much of this species' range, however, is adversely affected by forest degradation through selective cutting and repeated burning.

**Bibliography.** Bingham (1903), Collar (2006), Edelman (2006), Hume & Davison (1878), Lekagul & Round (1991), Oates (1894), Robson (2000), Round (1983), Smith *et al.* (1940, 1943), Smythies (1986), Stattersfield *et al.* (1998).

## Genus *STAPHIDA* Gould, 1871

### 24. Striated Yuhina

#### *Staphida castaniceps*

**French:** Yuhina à tête marron

**German:** Rotohyuhina

**Spanish:** Yuhina Estriada

**Other common names:** White-browed/Chestnut-headed Yuhina

**Taxonomy.** *Ixulus castaniceps* F. Moore, 1854. Afghanistan; error = Khasi Hills, Assam, India. Usually placed in genus *Yuhina*. Formerly treated as conspecific with *S. torqueola* and, normally, *S. everetti*. Four subspecies recognized.

**Subspecies and Distribution.**

*S. c. rufigenis* (Hume, 1877) – Sikkim and Darjeeling E to Bhutan and NE India (W Arunachal Pradesh).

*S. c. plumbeiceps* Godwin-Austen, 1877 – NE India (E Arunachal Pradesh S to Nagaland), N Myanmar and S China (W Yunnan).

*S. c. castaniceps* (F. Moore, 1854) – NE Indian hill states (W & S of Nagaland), SE Bangladesh, and W & SW Myanmar.

*S. c. striata* (Blyth, 1859) – E & S Myanmar (including Tenasserim) and NW & W Thailand.

**Descriptive notes.** 13–14 cm; 10–17 g. Small, dull yuhina with short crest, brown above, off-white below, with white-streaked rufous-tan ear-coverts; graduated tail. Nominative race has forehead and crown feathers dull rufous-brown, broadly fringed pale greyish-brown, shading on rear crown and upper nape to plainer rufous-tan; lower nape and upperparts drab greyish-brown with slight pale olive-brown tinge, and very indistinct whitish shaft streaks (virtually invisible); primary coverts, upperwing and tail brown, flight-feathers with pale edges, tail with increasingly large white tips on outer feathers; lores and narrow supercilium buffy whitish, supercilium short and eyebrow-shaped (ending not far behind eye), cheek and ear-coverts rufous-tan with faint and very narrow whitish shaft streaks, submoustachial area and underparts whitish, tinged very pale creamy-buffish; iris reddish-brown to dull crimson, orbital ring dotted whitish; bill pale horn-brown; legs orange-brown to brownish-flesh. Sexes similar. Juvenile is duller than adult, with shorter crest. Races differ mainly in colour of crown (rufous only on nominate) and in strength of upperparts streaks, also in tone of upperparts and underparts: *rufigenis* has crown to upper nape dull mid-grey with darker feather centres, but lateral crownstripe (behind eye) rufescent like ear-coverts, upperparts a shade less rufescent and more obviously marked with white shaft streaks; *plumbeiceps* is similar to previous, but upperparts slightly more greyish-olive, contrasting less with crown, underparts whiter, less buff-tinged; *striata* is also similar, but streaks on crown and upperparts more numerous and more clearly defined, extending to nape and rump, ear-coverts duller and paler, underparts as last. Voice. Song a simple series of high-pitched shrill "tchu", "tchi" or "tchi-chi" notes. Flock-members utter continuous loud chattering, interspersed with squeaky high-pitched notes; calls of nominate race include excited, rapid, dry, short churring trills, irregular sputtery trills and chattering, often in chorus, sometimes oscillating in pitch, tempo and rhythm, also short, clear, slightly nasal peeps.

**Habitat.** Middle storey, scrub and undergrowth of broadleaf evergreen forest, shrubby undergrowth in secondary forest, lower canopy and tall undergrowth. At 300–1590 m in Indian Subcontinent, 600–1600 m in Bhutan; 600–1800 m, locally down to 180 m, in SE Asia.

**Food and Feeding.** Mainly insects (and often visits aphid-infested trees); also seeds, e.g. of the bamboo *Dendrocalamus longispatus*, and nectar. Extremely gregarious all year, with largest flocks (mean 20 individuals) in Aug–Feb, smaller (mean 15) in Mar–Apr, and smallest (mean 8) in May–Jul; sometimes associates with mixed-species foraging parties. Flocks move very quickly in sweeping movements. Forages in higher bushes and lower trees, searching among moss, lichen and loose leaf litter on branches.

**Breeding.** Apr–Jul in India, Mar–Jun in Myanmar and Jan–Mar in Thailand. Nest a compact, more or less stiff, deep cup made of moss, dead leaves, leaf skeletons, grass stems, roots and fibres, lined with very fine soft lichen strands and seed stems, bark fibre, silk-like vegetative matter, palm fibre, soft black fibre, rootlets, hair, coir and moss roots (lining usually fitted within rough outer nest which more or less fully enclosed cavity); placed up to 2 m above ground in unoccupied bee-eater (Meropidae) or kingfisher (Alcedinidae) hole or natural hole in steep bank, often in roadside cutting, or just inside hole in small perennating bank (e.g. on upper side of hill path) or in cavity in rocks. Clutch 2–4 eggs, usually 3 or 4, glossy white or with faint bluish or greenish tinge, with small to large brown or reddish-brown spots, and blotches often mixed with few pale purple spots. Incubation by both sexes, period c. 12 days; no information on nesting period. Nests often preyed on abundantly by tree shrews (*Myiarchus*) in Tenasserim (Myanmar).

**Movements.** Resident; some evidence suggesting seasonal altitudinal displacements, but none proven.

**Status and Conservation.** Not assessed. Fairly common in Himalayan foothills, but not very common in Bhutan, where occasionally recorded in C & E valleys and foothills, and present in Thrumshingla National Park. In India, common in W Nagaland, Manipur and hills of Assam, and present in Buxa Tiger Reserve (West Bengal) and in (at least) Namdapha and Mouling National Parks (Arunachal Pradesh) and Dampa Tiger Reserve (Mizoram). Formerly resident in Bangladesh, but no recent records. Common in W Yunnan (China), in W Myanmar including Natunataung National Park, and in NW & W Thailand including Umphang Wildlife Sanctuary.

**Bibliography.** Ali & Ripley (1972), Allen *et al.* (1997), Birand & Pawar (2004), Cheng Tsohsin (1987), Collar (2006), Deignan (1963), Duckworth *et al.* (1998), Evans & Timmins (1998), Grimmett *et al.* (1998), Harrington (1914a), Hopwood (1919), Hopwood & Mackenzie (1917), Huang Qiang *et al.* (1993), Hume & Davison (1878), Inskipp & Inskipp (1993b), Inskipp *et al.* (2000), Katti *et al.* (1992), Lê Manh Hùng *et al.* (2002), Lekagul & Round (1991), Meyer de Schauensee (1984), Nguyễn Đức Tú *et al.* (2001), Oates (1883), Rasmussen & Anderton (2005), Ripley (1952), Robson (2000), Singh (1995), Smith *et al.* (1940, 1943), Smythies (1986), Spierenburg (2005), Stanford & Mayr (1941), Stanford & Ticehurst (1938), Stevens (1914, 1923), Stresemann & Heinrich (1940a), Stuart Baker (1893), Thompson & Johnson (2003), Ticehurst (1933), Tizard *et al.* (1997), Wu Zhikang *et al.* (1986).

### 25. Chestnut-collared Yuhina

#### *Staphida torqueola*

**French:** Yuhina à bandeau

**German:** Kastanienohryuhina

**Spanish:** Yuhina Indochina

**Other common names:** Collared/Indochinese Yuhina

**Taxonomy.** *Siva torqueola* Swinhoe, 1870, Tingchow Mountains, Fujian, China.

Usually placed in genus *Yuhina*. Formerly treated as conspecific with *S. castaniceps* and, normally, *S. everetti*. Monotypic.

**Distribution.** S & SE China (SC Sichuan and E Yunnan E to W Hubei and Zhejiang, S to S Guangxi and Hong Kong), N Thailand, Laos and Vietnam (Tonkin, N & C Annam).

**Descriptive notes.** 14–15 cm; 12–16 g. Crown is dark grey with slightly paler fringes, sharply demarcated from chestnut-rufous hindcrown and nape with narrow long white streaks; mantle rufous-olive, shading to olive-brown on remaining upperparts, with narrow long whitish streaks on mantle to upper back; upperwing and tail grey-brown, tail with broad white tips on outer feathers; lores grey, narrow postocular stripe whitish, submoustachial area slightly glossy chestnut with white dots, cheek and ear-coverts the same and with white shaft streaks; chin, malar area, throat, breast and central belly whitish, breast side and flanks unevenly

marked with vague greyish-buff, thighs greyish-buff; iris reddish-brown to dull crimson or dark red; bill dark pinkish-brown; legs pinkish-brown. Differs from similar *S. castaniceps* (of race *striata*) in being slightly larger and larger-billed, with richer rufous-chestnut ear-coverts with bold white streaks extending around nape in broad chestnut-rufous collar, broader and pale greyish postocular supercilium with prominent white shaft streaks (forming restricted whitish eyebrow), warmer brown upperpart, cleaner and whiter underparts. Sexes similar. Juvenile is very like adult, but has upperparts tinged brown, edges of secondaries and wing-coverts browner. Voice. Song a loud "tu-whi" or "t-whi" (second part rising). Calls include continuous loud chattering and high squeaks by flock-members, also short dry trills and nasal notes, all similar to calls of *S. castaniceps*.

**Habitat.** Scrub and undergrowth in broadleaf forest, shrubby undergrowth in secondary forest, lower canopy and tall undergrowth; usually at 350–2200 m, mainly above 900 m.

**Food and Feeding.** Mainly insects, also seeds; visits various tree blossoms for nectar; often visits aphid-infested trees. Found in pairs during breeding season; otherwise in parties of up to 20–30 individuals, usually in single-species flocks, but often associates with other species. Flocks move very quickly and noisily in sweeping and swerving movements through trees. Forages in higher bushes and lower trees, searching among moss, lichen and loose bark on branches.

**Breeding.** Apr–Jul in China, Feb–Mar in Thailand and May–Jun in Vietnam; double-brooded. Partly a social breeder. Nest a compact cup built mostly by female, but 3–4 birds building single nest in Vietnam, made of moss and leaf skeletons, lined with palm fibre, rootlets and hair, based on coarser material and placed in hole in bank under shade of projecting ledge. Clutch 3–5 eggs (captive female repeatedly laid clutches of 5 eggs), white or with faint bluish or greenish tinge, dotted and speckled with various shades of brown, dark grey and black, and some light and dark grey spots; in captivity, incubation by both of pair, from last egg; incubation period 12 days, nestling period 10–11 days.

**Movements.** Chiefly resident. In S China, noted as irruptive, being common and widespread in some years and absent in others, e.g. in winter in Hong Kong, typically Nov–Mar.

**Status and Conservation.** Not assessed. Fairly common and widespread in S China, where judged the commonest yuhina and recently recorded at 29 (54%) of 54 sites surveyed (of which 52 are protected areas), including Shiwandashan National Nature Reserve, where common; irruptive winter visitor in Hong Kong, with small resident population of captive origin. In Laos, common in Nakai-Nam Theun National Biodiversity Conservation Area (NBCA) and present in Hin Namno, Nam Kading and Phou Khao Khoay NBCAs and in proposed extension to Nakai-Nam Theun NBCA. Present in Ba Be National Park and Na Hang Nature Reserve and common at Tam Dao National Park, in N Vietnam, and present in three protected areas in Annamese Lowlands Endemic Bird Area.

**Bibliography.** Bosche (2006), Caldwell & Caldwell (1931), Carey *et al.* (2001), Cheng Tsohsin (1987), Collar (2006), David-Beaulieu (1939, 1944), Davidson (1998), Deignan (1963), Delacour & Jabouille (1931a), Eames *et al.* (2001), Hill (2000), King & Han Lianshan (1991), King & Zheng Guangmei (1988), La Touche (1925–1930), Lee Kwok Shing *et al.* (2006), Lekagul & Round (1991), Lewthwaite (1996), Liu Kezhi *et al.* (1994), Lülfing (1984), Meyer de Schauensee (1984), Pfeiffer (1993), Robbins *et al.* (2006), Robson, Eames, Nguyễn Cu & Truong Van La (1993a), Robson, Eames, Wolstenecroft *et al.* (1989), Showler, Davidson, Chanthavi Vongkhamheng & Khounmee Salivong (1998), Showler, Davidson, Khounmee Salivong & Khamkhoun Khounholine (1998), Stevens (1914, 1923), Tedbury (1995), Viney *et al.* (1994), Wu Zhikang *et al.* (1986), Yen Kwok-ung (1934a).

### 26. Chestnut-crested Yuhina

#### *Staphida everetti*

**French:** Yuhina de Bornéo

**German:** Rotschopfyuhina

**Spanish:** Yuhina de Borneo

**Taxonomy.** *Staphidia* [sic] *everetti* Sharpe, 1887, Kinabalu, north Borneo. Usually placed in genus *Yuhina*, and sometimes in *Minla*. In past, normally treated as conspecific with *S. castaneiceps* and *S. torquata*. Monotypic.

**Distribution.** Borneo.

**Descriptive notes.** 14–15 cm. Crown and nape are rufous-tan with very slightly paler fringes, cutting sharply to dull olive-grey upperparts and darkish grey-brown upperwing and tail, tail with broad white tips on outer feathers; lores and narrow short supercilium white, ear-coverts as crown, submoustachial area white, very narrow indistinct malar line rusty-tan; chin to vent whitish, with dull greyish thighs; iris chocolate-brown or very dark or dull brown to chestnut; bill dark grey or dark brown to blackish; legs light brown or greyish-brown to brownish-flesh. Distinguished from very similar *S. castaneiceps* (nominat race) by larger

size, plainer and more rufous crown and ear-coverts, lacking buffy-grey frontal scaling, whiter and more contrasting lores and supercilium, a shade darker upperparts virtually lacking pale streaks. Sexes similar. Juvenile is presumably very similar to adult. **VOICE.** Song apparently unreported. Contact calls are combinations of low quick “whit”, “chik” and “yik” notes; alarm call a harsh rattling “chr-r-r-r-r-r”, “chrr-r-r” and “yrr-r-r-r”; chicks produce hurried chatter when excited, before and during flight.

**Habitat.** Generally submontane and montane broadleaf evergreen forest, moss forest, also kerangas, forest edge and secondary growth, at 100–2800 m.

**Food and Feeding.** Insects such as moths (Lepidoptera); also seeds, berries and fruit, including those of *Bridelia*, *Glochidion*, *Macaranga*, *Mallotus javanicus* and *Mallotus macrostachyus*, *Trema*, soft white berries of *Pipturus* and small purple figs, also nectar of *Eugenia*; grass seeds taken in drought conditions. Found in fast-moving noisy flocks of 6–12 or up to 20 or more individuals; sometimes joins mixed foraging flocks, but often monospecific groups of this species attract other birds owing to insects flushed by their rapid passage. Seen to enter cavities in moss, apparently in pursuit of invertebrates.

**Breeding.** Nov–Aug in N (Sabah). Nest with four young seen attended by at least four adults, suggesting co-operative breeding. Nest a cup of moss, roots, fibres and grasses, lined with rootlets, fine fibres, dried grass fibres and bits of bark, placed 0.5–0.6 m above ground in often moss-covered recess in trailside bank, riverbank or other suitable place. Clutch 1–6 eggs, usually 3, white or pinkish-white, spotted and/or streaked with mid-brown or dark reddish-brown to red-purple. No information on incubation and nesting periods. Nests parasitized by cuckoos (Cuculidae), and this species seen to mob Moustached Hawk-cuckoo (*Cuculus vagans*).

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Bornean Mountains EBA. Fairly common to common throughout range. Common in Sabah; in some places (e.g. Mt Kinabalu) the commonest flocking bird in area; present in Kutai and Kayan Mentarang National Parks, in E Kalimantan, and in Gunung Palung National Park and Gunung Niut Nature Reserve (very common above 500 m), in W Kalimantan.

**Bibliography.** Collar (2006), Davison (1992), Duckworth & Kelsch (1988), Eames (2005), Finsch (1905), Fogden (1964), Holmes (1997), Priemé & Heegaard (1988), Sharpe (1889), Sheldon *et al.* (2001), Smythies & Davison (1999), Stattersfield *et al.* (1998), Thompson (1966), Wilkinson, Dutton & Sheldon (1991), Wilkinson, Dutton, Sheldon, Darjono & Noor (1991).

## Genus *DASYCROTAPHA* Tweeddale, 1878

### 27. Flame-templed Babbler

#### *Dasycrotapha speciosa*

**French:** Timalie précieuse **German:** Goldstirn-Buschtimalie **Spanish:** Timali Frentigualdo  
**Other common names:** Orange-templed/Rough-templed Babbler, Beautiful Rough-templed, Rusty-crowned Babbler

**Taxonomy.** *Dasycrotapha speciosa* Tweeddale, 1878, Valencia, Negros, Philippines.

Commonly placed in genus *Stachyris*. The populations on the two islands are reported to differ from one another sufficiently to warrant recognition of two races; further investigation required. Monotypic.

**Distribution.** Panay and Negros, in WC Philippine Is.

**Descriptive notes.** 13 cm. Remarkable small babbler, greyish-green with complex head pattern of yellow, orange, black and white. Brightly lores and forehead are yellow, centre of crown black, bright orange supercilium tufts above eye, hindcrown pale olive-yellow, black half-collar on hindneck adjoining black ear-coverts, latter with long white shaft streaks; black cheek and central submoustachial area, yellow interramal area, upper submoustachial tufts and chin; upperparts olive-grey with long whitish shaft streaks, rump olive-green, upperwing and tail olive-brown with olive-yellow fringes; throat to breast yellow with

large black spots, shading to olive-yellow on flanks, belly and vent; iris red-brown, yellow orbital skin, some exposed pale blue-grey skin behind eye, bill pale orange, legs olive. Sexes similar. Juvenile is like adult. **VOICE.** Song pleasant and musical, of 7–10 quickly delivered, rather slurred sweet notes, starting faintly, but gathering in volume, “iwi-iwi-wi-wi-yi-wee-wee” or “i-wi-ti-chi-wi-wi-wi”, lasting 2–2.5 seconds, repeated every 6–10 seconds; starts high-pitched, then becomes more spaced and fluty, similar to speeded-up song of *Mesia argentea*. Contact calls are soft “yir”, “ju”, “chu” and “ju-jrrr”.

**Habitat.** Thick undergrowth and understorey in primary forest, secondary forest and degraded secondary forest, also forest edge, at 75–1180 m. Requirements not well understood, although

perhaps a forest-edge specialist, absent from some tracts of apparently suitable degraded and secondary forest.

**Food and Feeding.** Insects, including large ones, reported. Forages unobtrusively in undergrowth close to ground and in understorey bushes and in middle-storey trees up to 10 m, also in dense tangles of vines and ferns on larger trees. Often feeds in slow, methodical fashion among trapped bunches of leaves, but may move very quickly through undergrowth. Found singly or in small parties of up to three or more individuals, often associating in mixed flocks with other species, e.g. fantails (*Rhipidura*), leaf-warblers (*Phylloscopus*) and tailorbirds (*Orthotomus*).

**Breeding.** Season on Negros apparently extended: breeding-condition birds in Feb, Apr, May, Aug and Dec, territorial behaviour in late Mar and early Apr, and juvenile and birds with brood patches in Aug. No further information.

**Movements.** Resident.

**Status and Conservation.** ENDANGERED. Restricted-range species: present in Negros and Panay EBA. Known from five localities on Panay (all found since 1980) and from 18 on Negros (five with post-1980 records). Formerly judged fairly common and widespread, but now generally uncommon and declining, the species evidently disappearing from many lower-lying areas on Negros owing to deforestation. On Panay very uncommon and/or very patchy, and most of the island is apparently unsuitable. On Mt Canlaon, on Negros, fieldwork in 1991 yielded a very approximate density of 0.22 birds/ha, but area of forest very limited. Continuing forest destruction a major problem, even second growth being cleared so rapidly that fears for the species’ survival were expressed in early 1990s. Present in Mount Canlaon National Park and North Negros Forest Reserve.

**Bibliography.** Anon. (2006d), Brooks *et al.* (1992), Butchart & Stattersfield (2004), Collar, Andreev *et al.* (2001), Collar, Mallari & Tabaranza (1999), Dickinson *et al.* (1991), Evans, Dutton & Brooks (1993), Hachisuka (1935), Kennedy *et al.* (2000), Lambert (1993), Mallari *et al.* (2001), McGregor (1909), duPont (1971), Rand (1951), Ripley & Rabor (1956), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

## Genus *STERRHOPTILUS* Oberholser, 1918

### 28. Mindanao Pygmy Babbler

#### *Sterrhoptilus plateni*

**French:** Timalie pygmée **German:** Zwergbuschtimalie **Spanish:** Timali de Mindanao  
**Other common names:** Platen’s Babbler, Pygmy Tree-babbler

**Taxonomy.** *Mixornis Plateni* A. W. H. Blasius, 1890, Mindanao, Philippines.

Genus usually merged into *Stachyris*. Until recently considered conspecific with *S. pygmaeus*. Monotypic.

**Distribution.** Mindanao, in S Philippines.

**Descriptive notes.** 10 cm; 7.5–10 g. Tiny babbler, mid-brown above and greyish-whitish below, with striking white-streaked dark head, throat and breast. Forehead is almost black, crown and ear-coverts dull chestnut, all with bold white shaft streaks; upperparts rust-tinged brown with obscure pale shaft streaks, upperwing and tail mid-brown; chin, throat and upper breast rich chestnut-brown with bold clean white shaft streaks, heaviest on chin; lower breast to undertail-coverts pale grey, flanks rusty buff; iris whitish or very pale grey; bill slate-blue; legs blackish. Sexes similar. Juvenile apparently undescribed. **VOICE.** Calls include quiet

“ichik”, “chik” or “chit” notes, sometimes repeated as series in quick succession, “chik-chik-chik-chik-chik” or “chidididit”; a quiet “dzhou dzhou dzhou” and “tsieu tsieu...tsieu tsieu tsieu”.

**Habitat.** Primary and secondary forest, forest edge and second growth, low fruiting trees in abandoned cultivation, and occasionally fruiting trees in cultivated areas near forest; at 100–1100 m.

**Food and Feeding.** Insects, some small fruits. Found in pairs or small parties, often in company with other species, including other babblers, in mixed flocks. More active and mobile than other members of genus. Forages in middle storey 3–6 m up, occasionally ascending to 12 m in lower canopy. Sometimes hangs upside-down when feeding; occasionally sallies for insects.

**Breeding.** Birds in breeding condition in Mar–May. Nest materials include white fluffy (seed) matter. No other information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. When treated as conspecific with *S. pygmaeus*, considered Near-threatened. Restricted-range species: present in Mindanao EBA. Apparently uncommon to rare throughout range, as forest at lower elevations being extensively destroyed. Recorded from some sites (Apo, Kitanglad) which are now established as national parks, but not known if current extent of forest there secures any population.

**Bibliography.** Blasius (1890b), Butchart & Stattersfield (2004), Collar (2006), Collar *et al.* (2001), Delacour & Mayr (1945, 1946), Dickinson *et al.* (1991), Hachisuka (1935, 1936), Ilomskov (1996), Kennedy *et al.* (2000), McGregor (1909), Ogilvie-Grant (1897), duPont (1971), Rand & Rabor (1960), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

### 29. Visayan Pygmy Babbler

#### *Sterrhoptilus pygmaeus*

**French:** Timalie de Samar **German:** Koboldbuschtimalie **Spanish:** Timali Pigmeo

**Taxonomy.** *Zosterornis pygmaeus* Ogilvie-Grant, 1896, Samar, Philippines.

Genus usually merged into *Stachyris*. Until recently treated as subspecies of *S. plateni*. Monotypic.

**Distribution.** Samar and Leyte, in EC Philippines.

**Descriptive notes.** 10 cm. Plumage is dull olive-brown above, slightly warmer on crown, lores darker brown than crown and this colour riding over eye in vague supercilium; mid-grey to greyish-olive from chin to breast and flanks, with diffuse white streaks along shafts making soft pattern spreading out from chin, flanks greyish-white; iris has outer ring vermilion or red, inner ring pale yellow, bill slate-blue; legs slate-grey. In addition to details of coloration, differs markedly from

*S. plateni* in having shorter bill, wing and, especially, tail. Sexes similar. Juvenile apparently undescribed. Voice. Presumably similar to that of *S. plateni*.

**Habitat.** Primary and secondary forest, forest edge and second growth, at 100–1100 m.

**Food and Feeding.** Insects, some fruits. Found in pairs or small parties, often in mixed flocks with other species, including other babblers. Forages in middle storey, occasionally ascending to lower canopy. Sometimes hangs upside-down when foraging; will sally for insects.

**Breeding.** Birds in breeding condition in Apr and May. No other information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. When treated as conspecific with *S. plateni*, considered Near-threatened. Restricted-range species: present in Eastern Visayas EBA. Not well known. Apparently uncommon to rare throughout range, as forest at lower edges being extensively destroyed.

**Bibliography.** Bourns & Worcester (1894), Collar (2006), Delacour & Mayr (1945, 1946), Hachisuka (1935), Kennedy *et al.* (2000), McGregor (1909), Ogilvie-Grant (1896b, 1897), Whitehead (1899).

### 30. Golden-crowned Babbler

#### *Sterrhoptilus dennistouni*

**French:** Timalie à calotte dorée

**Spanish:** Timali Coronadoro

**German:** Goldkappen-Buschtimalie

**Other common names:** Golden-crowned Tree-babbler

**Taxonomy.** *Zosterornis dennistouni* Ogilvie-Grant, 1895, Cape Engaño, north-eastern Luzon, Philippines.

Genus usually merged into *Stachyris*. May form a superspecies with *S. nigrocapitatus* and *S. capitalis*, and all three have been treated as conspecific. Monotypic.

**Distribution.** Luzon (Northern Sierra Madre Mts; one record Ilocos Norte), in N Philippines.

**Descriptive notes.** 13–14 cm. Distinctive small, slightly crested babbler, grey-olive above and pale yellow-buff below, with strong yellow crown and throat and contrasting black bill. Forehead and crown are bright yellow (crown feathers slightly elongate and stiffly filamentous), shading to greyish-olive with yellow shaft-streaks on hindcrown, nape and neck side, and to duller brown-tinged grey-green upperparts with whitish shaft streaks; upperwing and tail dull brown, wing feathers with pale buffy-grey fringes, tail with white-tipped outer feathers and white outer web of outermost rectrix; submoustachial area, cheek

and ear-coverts pale olive-grey with yellowish-white shaft streaks; throat yellow, breast and belly yellowish-white, flanks and thighs grey-tinged; iris deep red to red-brown; bill black; legs olive-brown to greyish-blue. Sexes similar. Juvenile is like adult. Voice. Noisy, fast series of 3–5 notes, “pilit-pilit-pilit”, followed by 5–7 slower pulsing notes, “poo poo poo poo poo”; “wit-wit-wit-wi-wi-wi-wu”, ending higher and more sibilant; “wi-wi-wi-wi-pr-pr-pr”, starting high and ending more slurred; and “wi-wi-wi-wi-pr-pr-piu-piu-piu”; also a quiet “wit-wit”, “pi” and “pri-pri-pri”, “prie-prie-prie”, etc.

**Habitat.** Primary forest, selectively logged and degraded forest and forest edge, bamboo, and adjacent tall-grass areas; prefers forest with more than 90% canopy cover but with very dense understorey covering 60–90% of floor (0–3 m), with young trees, rattans, bamboo, ferns and creepers. Sea-level to 1150 m.

**Food and Feeding.** Presumably invertebrates. Found singly, in pairs or in small parties of up to four individuals, often in association with other species. Forages 1–15 m above ground, usually at c. 5 m. Observed to use foliage-gleaning.

**Breeding.** Birds in breeding condition in Apr, nest found in May, and nestlings and fledglings in May and Jul. One nest a cup of woven mosses, hair-like roots and small twigs, suspended between several branches of bush 1 m from ground; contained two nestlings. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Luzon EBA. Locally fairly common to common, e.g. common at Dimapnat, and fairly common at Palanan, Dagupan, Abuan and Minuma. Potentially at risk from deforestation within its small range. Present in Northern Sierra Madre Natural Park.

**Bibliography.** Butchart & Stattersfield (2004), Collar *et al.* (2001), Dickinson *et al.* (1991), Hachisuka (1935, 1936), Hornsby (1996), Kennedy *et al.* (2000), McGregor (1909), DuPont (1971), Poulsen (1995), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Whitehead (1899).

### 31. Black-crowned Babbler

#### *Sterrhoptilus nigrocapitatus*

**French:** Timalie à calotte noire

**Spanish:** Timali Coroninegro

**German:** Schwarzkappen-Buschtimalie

**Other common names:** Black-crowned Tree-babbler

**Taxonomy.** *Mixornis nigrocapitatus* Steere, 1890, Samar and Leyte, Philippines.

Genus usually merged into *Stachyris*. May form a superspecies with *S. dennistouni* and *S. capitalis*, and all three have been treated as conspecific. Three subspecies recognized.

**Subspecies and Distribution.**

*S. n. affinis* (McGregor, 1907) – S & SE Luzon, in N Philippines.

*S. n. nigrocapitatus* (Steere, 1890) – Samar and Leyte, in EC Philippines.

*S. n. philippinus* (Rand & Rabor, 1957) – Bohol, in SC Philippines.

**Descriptive notes.** 13–14 cm. Small dusky babbler, grey-brown above and whitish below, with strongly rufous blackish crown, rusty malar and yellowish throat. Nominative race has forehead and crown black (crown feathers slightly elongate and spiky), hindcrown and rear super-

cilium tinted greyish-chestnut, nape greyish-ochre, shading on upperparts to dark dull greyish-olive with whitish shaft streaks; upperwing and tail dull dark brown, tail with white-tipped outer feathers and white outer vane of outermost rectrix; lores greyish, submoustachial area, cheek and ear-coverts greyish with fine whitish shaft streaks, short malar dull rusty-chestnut; chin and throat yellow with vague narrow rusty lines, breast and belly pale grey with yellowish wash, breast side and flanks greyish; iris red-brown, outer ring red and inner ring pale yellow; bill black; legs olive-brown to dull lead-blue. Sexes similar. Juve-

nile has crown brownish and scapulars darker, both with whitish shaft streaks, chin and throat paler, outer webs of primaries pale sandy. Race *affinis* has upperparts more olive than nominate, throat rusty with yellow wash, underparts heavily washed olive-yellow; *hoholensis* has reduced rusty malar, unstreaked yellow throat, less greyish-chestnut on nape and behind eye. Voice. Song appears to be a short series of “whit” notes running into a level or descending series of “du” or “diti” notes; transcribed also as “wi-wi-wi-wi-wi-wi”, “wi-wi-wi-wi-wi-wi-wi” and “wit-wit-wit-wit-wi-wi-whoi-whoi”. Contact call a series of quiet “whit” or “whut” notes, or “wuc-wuc”.

**Habitat.** Inhabits undergrowth in primary evergreen forest, thick forest, and forest edge, at 100–1140 m.

**Food and Feeding.** No documented records of food; presumably small invertebrates and some vegetable matter. Found singly, in pairs or in small parties, often in association with other species, including other babblers, in mixed flocks. Forages in lower branches of trees, sometimes in canopy, 6–9 m above ground. A fairly slow and methodical feeder. Hunts by foliage-gleaning and by disturbing insects around dead leaves trapped in canopy of small trees. Sometimes hangs upside-down when feeding.

**Breeding.** Birds in breeding condition in Apr and May, nest-building in Apr, and nestlings in May and Jul. Nest, built by both sexes, a deep cup or cradle made of moss, fine black fibres and other plant fibres, sometimes a little white cotton-like material, lined with fine fern roots, suspended 1.2–1.25 m above ground between small twigs of bush or sapling. Clutch 3 eggs, pale greenish-blue. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare on Bataan Peninsula, on Luzon. Fairly common in Rajah Sikatuna National Park, on Bohol.

**Bibliography.** Brooks *et al.* (1996), Delacour & Mayr (1946), Dickinson *et al.* (1991), Gilliard (1950), Goodman & Gonzales (1990), Hachisuka (1935, 1936), Hornsby (1996), Kennedy *et al.* (2000), McGregor (1909), Ogilvie-Grant (1897), DuPont (1971), Rand & Rabor (1957, 1960), Whitehead (1899).

### 32. Rusty-crowned Babbler

#### *Sterrhoptilus capitalis*

**French:** Timalie mitrée

**German:** Gelbkehl-Buschtimalie

**Spanish:** Timali Mitrado

**Other common names:** Rusty-crowned Tree-babbler, Rufous-crowned Babbler(1)

**Taxonomy.** *Mixornis* (?) *capitalis* Tweeddale, 1877, Dinagat, Philippines.

Genus usually merged into *Stachyris*. May form a superspecies with *S. dennistouni* and *S. nigrocapitatus*, and all three have been treated as conspecific. Three subspecies recognized.

**Subspecies and Distribution.**

*S. c. capitalis* (Tweeddale, 1877) – Dinagat, in EC Philippines.

*S. c. euroaustalis* (Parkes, 1988) – Mindanao (excluding Zamboanga Peninsula), in S Philippines.

*S. c. isabellae* (Parkes, 1963) – W Mindanao (Zamboanga Peninsula) and Basilan, in S Philippines.

**Descriptive notes.** 14–15 cm; 14–19 g. Distinctive smallish babbler, with bold whitish streaks on head and upperparts, rusty crown and throat, and whitish underside. Nominative race has forehead and forecrown rusty-chestnut (crown feathers spiky and elongate, extending over crown), rest of crown, also head side (submoustachial area, cheek, ear-coverts), neck side, upperparts and upperwing-coverts dark olive-grey with bold whitish shaft streaks; flight-feathers darkish brown with whitish fringes, tail darkish brown with white-tipped outer feathers and white outer web of outermost rectrix; lores greyish with buffy-white

stippling, chin, throat and breast yellow with strong, uneven rusty suffusion, shading to pale yellow lower underparts, with greyish wash on flanks; iris red-brown or red with chestnut tinge; bill black; legs olive-brown to dull pale bluish-grey. Sexes similar. Juvenile is like adult. Race *isabellae* has more prominent shaft streaks on crown and back, upperparts slightly duller than nominate; *euroaustalis* has breast heavily suffused grey, sides and flanks extensively grey, vent mainly grey, crown more orange-brown. Voice. Song unrecorded, but probably very like that of *S. nigrocapitatus*. Call usually soft and bubbling, but may be fairly loud “whit” or “wyit”; may be repeated several times when alarmed, as “whit whit chew-chew-chew” in variable numbers of notes, one or more birds participating.

**Habitat.** Middle and lower storeys (occasionally lower canopy) of primary and logged forest, and forest edge; from lowlands to 1100 m.

**Food and Feeding.** No information on diet; presumably small invertebrates and some vegetable matter. Found singly, in pairs or in small parties, often in association with other species in mixed feeding flocks. Forages 1–2–12 m above ground, by foliage-gleaning, sometimes hanging upside-down to do so; seen to probe small wasp nests cemented to underside of leaves; occasionally sits motionless.

**Breeding.** Birds in breeding condition in Mar and Jun, and immatures in Feb, May and Aug. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Formerly considered Near-threatened. Restricted-range species: present in Mindanao and the Eastern Visayas EBA. Generally uncommon.

**Bibliography.** Delacour & Mayr (1946), Dickinson *et al.* (1991), Hachisuka (1935, 1936), Kennedy *et al.* (2000), McGregor (1909), Parkes (1988), DuPont (1971), Rand & Rabor (1960), Stattersfield *et al.* (1998).

## Genus *ZOSTERORNIS* Ogilvie-Grant, 1894

### 33. Chestnut-faced Babbler

#### *Zosterornis whiteheadi*

**French:** Timalie de Whitehead **German:** Brillenstreifentimalie **Spanish:** Timalí de Whitehead  
**Other common names:** Whitehead's Babbler/Tree-babbler

**Taxonomy.** *Zosterornis whiteheadi* Ogilvie-Grant, 1894, mountains of northern Luzon, Philippines.

Genus usually merged into *Stachyris*. Two subspecies recognized.

#### **Subspecies and Distribution.**

*Z. w. whiteheadi* Ogilvie-Grant, 1894 – N & C Luzon, in N Philippines.

*Z. w. sorsogonensis* (Rand & Rabor, 1967) – SE Luzon.

**Descriptive notes.** 15 cm; 17–27 g. Olive-green babbler, yellowish below, with dull grey crown and dull chestnut face. Nominant race has forehead, lores, narrow supercilium (to just behind eye), ear-coverts, cheek, submoustachial area, malar and chin dull rusty chestnut, thin darker eyebrow line inside supercilium; forehead whitish and grey, shading to dull medium grey on mid-crown to hindneck and to olive-green on upperparts; upperwing and tail greyish-brown with olive-green fringing; mid-throat and belly to vent yellow, breast and flanks tinged olive; iris brown to dark brown, white eyering broken at front; bill black; legs

olive or olive-green. Sexes similar. Juvenile apparently undescribed. Race *sorsogonensis* has crown, supercilium and ear-coverts edged with black. Voice. Call/song a loud, rapid, busy twittering of snappy sharp metallic notes, usually in long series and used as contact call by flock-members, “chip chip chip chip”, 4–5 per second, interspersed with 4–6 alternating “pe-chu pe-chu pe-chu pe-chu”, many birds calling simultaneously.

**Habitat.** Montane mossy forest, broadleaf evergreen forest, pine forest, open forest, secondary growth, scrub, tangled masses of high grass and small trees on mountainsides. Usually above 800 m (mainly above 1000 m), occasionally down to 100 m, and extending to 2600 m; abundant above 1400 m.

**Food and Feeding.** Seeds, fruit, small beetles (Coleoptera) and spiders (Araneae). Found singly, in pairs or in parties of up to 30 individuals, often in association with other species in mixed flocks. Usually feeds in middle to lower levels of vegetation but frequently ascends to canopy. Drinks water held in pitcher-plants.

**Breeding.** Birds in breeding condition in Apr–Jun. No other information.

**Movements.** Resident; records from Dalton Pass (migration bottleneck in C Luzon) suggest that some type of local displacement may occur, improbable as this seems.

**Status and Conservation.** Not globally threatened. Formerly considered Near-threatened. Restricted-range species: present in Luzon EBA. Common in Sierra Madre above 800 m, and abundant in mossy forests throughout range. Apparently able to survive in secondary growth and scrub. Present in areas under varying types of protection, notably Northern Sierra Madre National Park and Mount Isarog National Park.

**Bibliography.** Alonzo-Pascolan (1992), Dickinson *et al.* (1991), Goodman & Gonzales (1990), Hachisuka (1935), Kennedy *et al.* (2000), McGregor (1909), Morioka & Sakane (1979), DuPont (1971), Poulsen (1995), Rand & Rabor (1967), Stattersfield *et al.* (1998), Whitehead (1899).

### 34. Luzon Striped Babbler

#### *Zosterornis striatus*

**French:** Timalie striée **German:** Luzonstreifentimalie **Spanish:** Timalí Estriado  
**Other common names:** Striped Tree-babbler

**Taxonomy.** *Zosterornis striatus* Ogilvie-Grant, 1894, Isabela Province, Luzon, Philippines.

Genus usually merged into *Stachyris*. May form a superspecies with *Z. latistriatus*, *Z. nigrorum* and *Z. hypogrammicus*; has been thought possibly conspecific with first of those. Monotypic.

**Distribution.** Luzon (Northern Sierra Madre Mts and Bataan Peninsula), in N Philippine Is.

**Descriptive notes.** 13–14 cm. Smallest babbler, olive-green above and creamy yellow with extensive heavy blackish streaking below. Crown to rump are greyish olive-brown, former with vague darker grey streaks; upperwing and tail grey-brown, primaries with dull olive-yellow fringing; lores and frontal cheek buffy whitish, preocular supercilium and subocular ring blackish, rear cheek and ear-coverts pale greenish-grey, submoustachial area blackish with buff flecks; chin and upper throat creamy buff, becoming yellow-tinged from breast to belly and greyer on flanks, with blackish streaks beginning small and narrow

on lower throat but becoming long and broad on underparts; iris pale brown to mid-brown, white eyering broken before eye; bill black; legs dull olive to brownish-green or brownish-flesh. Sexes similar. Juvenile is like adult. Voice. Song, from treetops up to 15 m or so above ground, a high-pitched rapid series of “tsi” notes, accelerating to short trill but slowing with final “zeep zeep”

notes, lasting c. 2–5 seconds and repeated every c. 2–8 seconds, reminiscent of song of white-eye (*Zosterops*). Calls include high “tsi” note, sometimes reminiscent of a very loud Goldcrest (*Regulus regulus*), also ■ sharp metallic staccato trill, “tiptiptiptiptip...”, repeated every 5–6 seconds; others transcribed as “swip-swip”, “twip”, a rather metallic “tswip-tip” and “twip-twip”, sometimes combined into a kind of sub-song.

**Habitat.** Primary, secondary, selectively logged and degraded forest, bamboo forest, second growth, forest edge, and overgrown clearings, at 115–1000 m.

**Food and Feeding.** Berries, small fruits and insects. Found singly, in pairs or in small parties, often in association with other species, notably *Sterrhophilus dennisi*, in mixed flocks. Usually forages in middle and upper storeys but also down to upper lower storey, 1–2–6 m above ground; often in denser bushy parts of smaller trees. Hunts rather slowly and methodically around leaves.

**Breeding.** Two birds feeding intermittently on berries in early May were suspected to be feeding nestlings. No other information.

**Movements.** Resident, suggestion of some regional or elevational movement (common at site in Aurora in Feb, unrecorded at same locality in May), but this requires fuller investigation.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Luzon EBA. Although once judged rare and local, and formerly considered Vulnerable, now known to be common locally. Capable of persisting in heavily degraded forest and overgrown clearings; even so, actual and potential habitat loss within range is substantial. Present in Northern Sierra Madre National Park.

**Bibliography.** Anon. (2006d), Butchart & Stattersfield (2004), Collar *et al.* (2001), Dickinson *et al.* (1991), Gonzales & Kennedy (1990), Hachisuka (1935), Kennedy *et al.* (2000), McGregor (1909), Parkes (1971), DuPont (1971), Poulsen (1995), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Whitehead (1899).

### 35. Panay Striped Babbler

#### *Zosterornis latistriatus*

**French:** Timalie à raies larges **German:** Panaystreifentimalie **Spanish:** Timalí Rayado

**Taxonomy.** *Stachyris latistriata* Gonzales and Kennedy, 1990, 1–1 km SSW of peak of Mount Baloy, Barangay San Agustín, Municipality of Valderrama, Antique Province, Panay, Philippines. Genus usually merged into *Stachyris*. May form ■ superspecies with *Z. striatus*, *Z. nigrorum* and *Z. hypogrammicus*; arguably conspecific with *Z. nigrorum*, but vocally distinct; has also been considered possibly conspecific with *Z. striatus*. Monotypic.

**Distribution.** W Panay (Mt Baloy and adjacent peaks), in WC Philippine Is.

**Descriptive notes.** 15 cm; 24–32 g. Olive-green babbler with extensively dark-streaked creamy-yellow underside and creamy-white face. Blackish forehead shades to blackish-scaled dull olive-green on crown and neck side, upperparts dull olive-green; upperwing and tail greyish olive-brown, primaries with dull olive-yellow fringes, tail with vague rusty tinge; lores, supercilium, cheek, ear-coverts and submoustachial area creamy white, narrow dark eyestripe, moustachial line and malar line, last two meeting and curving up to form dark edge to rear ear-coverts; chin and upper throat cream-white, lower throat pale sulphur-yellow.

becoming buff-yellow on breast and belly, flanks greenish-olive, broad black streaks (varying in intensity) beginning on throat, most prominent on breast, fading to dark olive-green on belly and undertail-coverts; iris bright rusty, outer edge paler, creamy eyering; upper mandible dark horn, lower mandible dark horn at tip and paler towards cutting edge; legs bluish-olive. Sexes similar. Juvenile is less boldly streaked than adult. Voice. Song/call a series of 11–17 slightly ascending staccato trills, “chi chi-chi-chi-chi”, each 1–2 seconds long, repeated about ten times a minute for up to 2–5 minutes, with some sharp “tsik” notes and occasional chatter interspersed. Similar to that of *Z. striatus*.

**Habitat.** Mainly middle and upper storeys of montane evergreen forest, mossy forest, but all strata used; 1000–1900 m, mostly above 1400 m.

**Food and Feeding.** Insects, including beetles (Coleoptera) and cicadas (Cicadidae); also seeds. Found singly or in pairs, sometimes in small groups of three or more (breeding season). Forages mainly 3–12 m above ground, occasionally lower.

**Breeding.** Nest found in Oct and birds in breeding condition in Apr. One nest a cup made of live and dead mosses loosely woven together, lined with black hair-like roots of epiphytic ferns and larger stems from orchids, suspended c. 5 m above ground among small branches in centre of crown of small tree. Clutch 2 eggs. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Negros and Panay EBA. Common, and on Mt Baloy the most abundant bird species. Much suitable habitat remains on slopes steeper than 45 degrees, and this species is therefore likely to be relatively secure, but it has a tiny global range. Formerly considered Vulnerable.

**Bibliography.** Anon. (2006d), Butchart & Stattersfield (2004), Collar *et al.* (2001), Dickinson *et al.* (1991), Gonzales & Kennedy (1990), Kennedy *et al.* (2000), Ruthven (1990), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

### 36. Negros Striped Babbler

#### *Zosterornis nigrorum*

**French:** Timalie de Negros **German:** Negrosstreifentimalie **Spanish:** Timalí de la Negros  
**Other common names:** Negros Tree-babbler

**Taxonomy.** *Stachyris nigrorum* Rand and Rabor, 1952, Cuernos de Negros, Negros Oriental Province, Negros, Philippines.

On following pages: 37. Palawan Striped Babbler (*Zosterornis hypogrammicus*); 38. Grey-cheeked Fulvetta (*Alcippe morrisonia*); 39. Nepal Fulvetta (*Alcippe nipalensis*); 40. Mountain Fulvetta (*Alcippe peracensis*); 41. Black-browed Fulvetta (*Alcippe grotei*); 42. Brown-cheeked Fulvetta (*Alcippe poiocephala*); 43. Brown Fulvetta (*Alcippe brunneicauda*); 44. Javan Fulvetta (*Alcippe pyrrhoptera*); 45. Rufous-throated Fulvetta (*Schoeniparus rufogularis*); 46. Rusty-capped Fulvetta (*Schoeniparus dubius*); 47. Dusky Fulvetta (*Schoeniparus brunneus*); 48. Dark-fronted Babbler (*Rhopocichla atriceps*); 49. Tawny-bellied Babbler (*Dumetia hyperythra*).

Genus usually merged into *Stachyris*. May form a superspecies with *Z. striatus*, *Z. latistriatus* and *Z. hypogrammicus*; arguably conspecific with *Z. latistriatus*, but vocally distinct. Monotypic.

**Distribution.** Negros, in WC Philippine Is.

**Descriptive notes.** 14.5–15 cm. Forecrown and supercilium are black, rest of crown, neck side and upperparts olive; upperwing and tail dark greyish-brown, tertials and secondaries with whitish inner fringes (invisible on closed wing); lores whitish, cheek and frontal ear-coverts whitish with blackish flecks, rear ear-coverts olive with blackish flecks, submoustachial area white basally, black distally; chin and throat whitish, shading to yellowish on breast to belly, with narrow blackish shaft streaks on breast and broader, softer-edged, more greyish-olive streaks on belly and vent, olive-grey flanks and thighs; iris colour undocumented, believed dull reddish;

white orbital skin; bill black; legs dark grey. Differs from very similar *Z. latistriatus* in having black extending from forehead over eye, no obvious "tramlines" (moustachial and malar lines) in upper submoustachial area but lower submoustachial area black and pronounced, streaking below much thinner and olive-green, rather than blackish (also, tail reportedly more reddish, but this not apparent on skins). Sexes similar. Juvenile apparently unrecorded. **Voice.** Song a loud pure whistle (sometimes delivered as subdued version), "pli-hi pli-hi pli-hi" (or "pli-plie"), the first and third couplets rising and second and fourth falling, or "plea-he, plea-hü, plea-he, plea-hü"; a single burst also described as "tu-tu tutu soo". Contact call a soft continuous "tsip, tsip..." or short sharp "tzi", sometimes becoming a trill; also a high-pitched "weeet" and a double note.

**Habitat.** Montane forest, secondary and degraded forest, forest edge and adjacent banana plantations and dense bushes; at 900–1600 m, mainly above 1000 m.

**Food and Feeding.** Insects and small fruits. Found singly, in pairs or in small parties of up to c. 20 individuals; often in association with other species, including Philippine Bulbul (*Ixos philippinus*), Mountain White-eye (*Zosterops montanus*), Mountain Leaf-warbler (*Phylloscopus trivirgatus*), Blue-headed Fantail (*Rhipidura cyaniceps*) and Elegant Tit (*Periparus elegans*); a primary constituent of bird waves where common. Forages in foliage of understorey trees and bushes, occasionally ascending to c. 20 m in canopy (e.g. at sunset); once seen to feed among dead leaves hanging under head of banana plant.

**Breeding.** Female in breeding condition in Nov and birds with slightly enlarged gonads in Nov–Dec; dependent juvenile observed in Sept. No other information.

**Movements.** Resident.

**Status and Conservation.** ENDANGERED. Restricted-range species: present in Negros and Panay EBA. Confined to island of Negros, where known from only four sites: three on and around Mt Talinis (Cuernos de Negros), in S, and one on Mt Canlaon (single record of single bird), in N. Record at latter site not repeated, despite much fieldwork, so area unlikely to be of great value to species; Mt Talinis therefore the crucial (and indeed only post-1980) site. On Mt Talinis was rather common above 1050 m in 1991, but numbers may fluctuate between sublocalities on the mountain; moreover, area under some pressure from illegal logging and slash-and-burn colonizers, despite being under control of Philippine National Oil Corporation, which operates a large geothermal powerplant on the mountain, and despite these forests being the sole watershed for the human population in S of island.

**Bibliography.** Anon. (2006d), Brooks *et al.* (1992), Butchart & Stattersfield (2004), Collar, Andreev *et al.* (2001), Collar, Mallari & Tabaranza (1999), Dickinson *et al.* (1991), Evans, Dutton & Brooks (1993), Gonzales & Kennedy (1990), Hornskov (1996), Kennedy *et al.* (2000), Mallari *et al.* (2001), DuPont (1971), Rand & Rabot (1952), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

## 37. Palawan Striped Babbler

### *Zosterornis hypogrammicus*

**French:** Timalie de Palawan **German:** Palawanstreifenfimalie **Spanish:** Timali de Palawan  
**Other common names:** Palawan Tree-babbler, Buff-capped Babbler

**Taxonomy.** *Stachyris hypogrammica* Salomonsen, 1962, Mount Mantaling, Mantalingajan Range, Palawan, Philippines.

Genus usually merged into *Stachyris*. May form a superspecies with *Z. striatus*, *Z. latistriatus* and *Z. nigrorum*. Monotypic.

**Distribution.** SW Palawan (Mt Mantaling, Mt Borangbato), in W Philippine Is.

**Descriptive notes.** 14–15 cm. Has dull orangey-buff crown with dark markings at nape; dull buffy mid-grey head side to nape; upperparts olive-green, primary coverts dark brown, upperwing and tail greyish olive-brown, primaries with dull olive-yellow fringes; chin and throat whitish-buff to yellowish-grey, breast and belly olive-yellow with bold black streaks, flanks dull greyish olive-green; iris brown to chestnut-brown; bill blackish-horn, paler lower mandible; legs olive grey-horn. Differs from *Z. latistriatus* mainly in paler and plainer head, unstreaked throat. Sexes similar. Juvenile apparently undescribed.

**Voice.** Song described as such: a distinctive "zeep zeep zeep" second note highest, fourth lowest, may function as song. Reported as having varied calls, including "burbling noises".

**Habitat.** Montane evergreen forest, at 1000–2030 m.

**Food and Feeding.** Insects; seeds and vegetable matter found in two stomachs. In pairs and in small groups of five or so individuals, foraging at all levels in forest but mostly in canopy. Gleans from leaves and branches.

**Breeding.** Birds in breeding condition in Apr–May. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Palawan EBA. Common, and likely to be relatively secure in remoter montane habitat, but has tiny global range. Formerly considered Vulnerable.

**Bibliography.** Anon. (2006d), Butchart & Stattersfield (2004), Collar *et al.* (2001), Dickinson *et al.* (1991), Evans & Kennedy (1990), Kennedy *et al.* (2000), Mallari (1971), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

## Genus *ALCIPPE* Blyth, 1844

### 38. Grey-cheeked Fulvetta

#### *Alcippe morrisonia*

**French:** Alcippe à joues grises **German:** Grauwangenalcippe **Spanish:** Fulveta Carigris  
**Other common names:** Common/Red-eyed Fulvetta, Grey-eyed Nun-babbler

**Taxonomy.** *Alcippe morrisonia* Swinhoe, 1863, Taiwan.

Geographical variation slight, despite number of named races. Nevertheless, future splitting of species possible on basis of vocalizations and genetic differences. Individuals of this species observed in C Yunnan and N & C Guangdong (S China) not yet assigned to race. Eight subspecies recognized.

**Subspecies and Distribution.**

*A. m. yunnanensis* Harington, 1913 – N Myanmar and S China (NW Yunnan, SW Sichuan).

*A. m. fratercula* Rippon, 1900 – C, E & S Myanmar, S China (SW Yunnan), N & W Thailand and NW Laos.

*A. m. laotiana* Delacour, 1926 – NC & C Laos and adjacent Vietnam (N Annam).

*A. m. schaefferi* La Touche, 1923 – S China (SE Yunnan E to S Guizhou and N Guangxi) and N Vietnam (Tonkin).

*A. m. davidi* Sytan, 1896 – EC China from S Gansu and S Shaanxi S to C & E Sichuan, SW Hubei, N & E Guizhou, SW Hunan, extreme NE Guangxi and NW Jiangxi.

*A. m. hueti* David, 1874 – SE China (SE Anhui and Zhejiang S to NE Guangdong).

*A. m. rufescens* (E. J. O. Hartert, 1910) – Hainan I.

*A. m. morrisonia* Swinhoe, 1863 – Taiwan.

**Descriptive notes.** 12.5–14 cm; 12–19 g. Small, soft-coloured nondescript "nun-babbler" with dull grey head, olive-grey upperparts and buffy-white underparts. Nominative race has crown to mantle and side of face to neck side rather dark slate-grey, long, vague dull blackish lateral crownstripe from above lores back to nape side; upperparts rufescent-tinged mid-brown, somewhat greyer and duller on mantle; upperwing and tail grey-brown, outer primaries with creamy buff fringes, carpal edge whitish; lores to upper bill base buffy white, chin and throat buffy white, shading buffier and greyer on breast side, flanks, thighs and

vent; iris crimson to dark crimson or chestnut, prominent broad whitish orbital ring; bill grey-brown to blackish-brown or black; legs grey-brown, tinged greenish or yellowish. Distinguished from congeners by combination of grey crown and head side to mantle, clear blackish lateral crownstrips, strong white eyering, distinctly buff underparts. Sexes similar. Juvenile has iris yellowish-brown or reddish-brown. Race *yunnanensis* has whitish-grey lores, greyish-buff chin and throat, and more extensively darker buff underparts than nominate; *fratercula* is like previous but less rich buff below, slightly warmer above, with more prominent lateral crownstrips; *laotiana* has strong lateral crownstrips like last, but is intermediate below between previous and following races; *schaefferi* is like *fratercula* but with very faint lateral crownstrips, usually warmer above, paler ventrally, greyish-white throat with very faint dark streaks, greyer malar area, pale slightly vinous wash on breast, whitish belly centre; *davidi* is very similar to previous, but head a shade browner, lateral crownstrips virtually invisible; *hueti* is similar but chin and throat greyer; *rufescens* is also similar, but darker-crowned and greyer on neck side. **Voice.** Song a repeated series of high-noted phrases, in NW Thailand "it-chi wi-wi", "ii chu chi-wi", "ii yu yu-wi" and "ii yu yu-wi", etc., in N Vietnam (E Tonkin) similar "it'i u-iwi-u-i-i" and "it'i-u-iwi-u-i-i", etc.; in all areas, song normally ends with 2–3 distinctive, curious buzzy "eerh" sounds. Calls with nervous "chr'r'r'r" and "chr'r'r'r'tt" and similar, and harsh "chittitit".

**Habitat.** Montane broadleaf evergreen forest, secondary forest, scrub, bamboo; in Taiwan prefers trees of the families Lauraceae and Fagaceae, but nests mostly in shrubs within forest. Found at 200–3050 m in mainland China, 600–3000 m in Taiwan (in N Taiwan 50–2780 m); 600–2565 m in SE Asia.

**Food and Feeding.** Small insects, seeds and berries. In 626 gut samples from Taiwan, invertebrates (arthropods) formed 85–90% and plant matter 10–15% of food in spring and summer, and respectively 35–55% and 45–65% in autumn and winter; arthropod composition of diet by volume was Hymenoptera 32%, Coleoptera 32%, Lepidoptera 10%, Diptera 9%, Homoptera 5%, Hemiptera 5%, Arachnida 3%, Orthoptera 2%, rest 2%, but with coleopterans eaten mainly in spring and summer and hymenopterans (ants, bees and wasps) mainly in autumn and winter. Commonest food fed to nestlings are larvae of Lepidoptera and Hymenoptera (79%). Keeps to middle storey and low undergrowth. In parties, often forms main component species of mixed feeding flocks, which may include other small babblers.

**Breeding.** Mar–Jul in mainland China, Apr–Aug (peak May–Jun) in Taiwan, and Feb–Jul in SE Asia; multi-brooded. Nest, built by both sexes, a very compact, fairly strong cup or hanging-basket, made of pliable strips of bark, leaf skeletons, bamboo or other leaves, leaf stems, fine twigs, grasses, pine needles, bits of fern skeleton, green moss and spider web, compactly lined with soft (often red or black) fibres, fern stems, pine needles, roots and fine twigs, placed 0.2–2 m above ground in low bush or bramble, suspended by rims from fern or dwarf bamboo stems or twigs of overhanging branches. Clutch 2–4 eggs, usually 4 in China and Taiwan (often 3 in latter), whitish to pinkish-white, irregularly mottled and streaked with rusty-red to pale rose over underlying markings of lavender, or (commonly in SE China) pale livid-pink with claret marks over violet-grey blotches with numerous short hair-lines; incubation by both sexes, more by female during day and exclusively by female at night, period 12–14 days; nestling period 9 days; young fed for 40–65 days after fledging. In one study in Taiwan, natural mortality 34% per year, owing mainly to cold weather in Jan–Feb; annual post-fledging disappearance rate varied from 53% to 86%.

**Movements.** Resident, some possible movement, as recorded only in winter in Hong Kong.  
**Status and Conservation.** Not globally threatened. Common in C & S China, and in S China recently recorded at 45 (83%) of 54 sites surveyed, including Shaxianshan National Nature Reserve and Diding Nature Reserve (Guangxi), in both of which common; has been considered the most abundant babbler in SE China. In Taiwan the most abundant bird species in Fushan forest, and judged perhaps most abundant species in woodland throughout island; recorded density of 0.06 birds/ha in mixed coniferous forest in Yushan National Park, although this not a preferred habitat. Generally common in SE Asian range; locally very common in Myanmar, common in Doi Inthanon

National Park, in Thailand; in Laos, present in Phou Dendin and Nam Kading National Biodiversity Conservation Areas (NBCA) and common in parts of Xe Bang Nouan NBCA and Nakai-Nam Theun NBCA; present in Tam Dao National Park, Ba Be National Park and Na Hang Nature Reserve, in N Vietnam, and in three protected areas in the Annamese Lowlands Endemic Bird Area. In Taiwan, typhoons may have severe impact on populations, e.g. 35% drop in numbers at start of 1998 breeding season following typhoon "Amber" in Aug 1997.

**Bibliography.** Caldwell & Caldwell (1931), Chen Chaohieh & Hsieh Fushing (2002), Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paolai (1960, 1962), Cheng Tsohsin *et al.* (1963), Chou Liansiang *et al.* (1998), David & Gosselin (2002a), David-Beaulieu (1944), Davidson (1998), Deignan (1963), Delacour & Jabouille (1931a), Ding Tzungsu *et al.* (2002a), Dowell *et al.* (1997), Duckworth *et al.* (1998), Eames *et al.* (2001), Evans & Timmins (1998), Fang Wei-horn (2005), Hachisaka & Udagawa (1950, 1951), Harrington (1909, 1914a), Hill (2000), Hu Meofen (1999), Huang Qiang, Deng Heli & Mao Ke (1995), Huang Qiang, Huang Yongzhao & Deng Heli (1993), Hume & Davison (1878), King (1987), King & Han Lianxian (1991), King & Liao Weiping (1989), King *et al.* (1998), Kinnear (1929), Koh Chaonien & Lee Pelfen (2003), Kuo Wei-wang (2000), La Touche (1899, 1923, 1925–1930), Lê Manh Hùng *et al.* (2002), Lee Kwok Shing *et al.* (2006), Lekagul & Round (1991), Lewthwaite (1996), Li Guiyuan, Liu Liangcai *et al.* (1976), Li Guiyuan, Zhang Qingmao *et al.* (1994), Li Peiyong (2003), Lin Ruyshing (1996), Liu Kezhi *et al.* (1994), Meyer de Schauensee (1984), Nguyễn Đức Tu *et al.* (2001), Oates (1883), Riley (1926), Robbins *et al.* (2006), Robson (2000), Robson *et al.* (1989), Rothschild (1926), Round (1999), Severinghaus & Blackshaw (1976), Shieh Baosen (2004), Showler, Davidson, Khounmee Salivong & Khamkhoun Khounholine (1998), Smith *et al.* (1940, 1943), Smythies (1986), Stanford (1935), Stanford & Mayr (1941), Stanford & Ticehurst (1938), Stresemann (1923c), Timmins & Trinh Viet Cuong (1999), Tizard *et al.* (1997), Tordoff, Lê Manh Hùng *et al.* (2002), Tordoff, Lê Trong Dat *et al.* (2001), Uchida & Kuroda (1916), Viney *et al.* (1994), Wang Zhijun (1983), Wang Zhijun & Wei Tianhao (1983), Wu Zhikang *et al.* (1986), Yen Chungwei (1990), Yu Zhiwei *et al.* (1986), Zhang Quntan *et al.* (1994), Zhao Xiubi (1994), Zheng Baolai (1988), Zheng Zuoxin & Qian Yanwen (1973), Zhou (1989).

## 39. Nepal Fulvetta

### *Alcippe nipalensis*

**French:** Alcippe du Népal **German:** Nepalalcippe **Spanish:** Fulveta Nepalesa  
**Other common names:** White-eyed/Black-eyebrowed Fulvetta, Nepal (Quaker) Babbler

**Taxonomy.** [Mesia] Siva *Nipalensis* Hodgson, 1837, Nepal. Proposed race *commoda*, from NE India (Assam) and N Myanmar, considered better merged with nominate. Two subspecies recognized.

**Subspecies and Distribution.**  
*A. n. nipalensis* (Hodgson, 1837) – Nepal E to Bhutan and NE India (Arunachal Pradesh, Assam, Nagaland, Manipur) and adjacent S China (SE Xizang) and N Myanmar.  
*A. n. stanfordi* Ticehurst, 1930 – E Bangladesh, NE India (Mizoram) and W Myanmar.

**Descriptive notes.** 12.5–13 cm; 13–18 g. Nominant race has crown to upper back pale brown-tinged grey, shading to pale warm brown on rest of upperparts, upperwing and tail, with soft-edged but broad blackish-brown lateral crownstreaks extending to mantle; lores whitish, supercilium, ear-coverts, cheek and submoustachial area and neck side pale brown-tinged grey (slightly paler than crown); chin whitish, shading to buffish-white on breast and to greyish-buff on flanks and thighs, mid-breast to mid-belly whitish; iris brown, white eyering; bill dark horn, pale base of lower mandible; legs pinkish-brown. Distinguished from similar

*A. morrisonia* (e.g. of race *yunnanensis*) by brown tinge on crown and nape, more pronounced blackish lateral crownstreaks, more rufescent upperparts and tail, pale lores and chin, stronger white eyering, whitish centre of throat, less buffy underparts. Sexes similar. Juvenile has upperparts, flanks and vent warmer-tinged than adult. Race *stanfordi* is paler and colder-tinged than nominate, with greyer crown and nape, slightly less distinct lateral crownstreaks. Voice. Song "chu-chui-chiwi" and "ew-ew-uw-uw", etc., described also as short, simple, rather well-spaced "uu-uw-uw" or "iii-uw-uw" and similar, and as "ee ooee-eww" or extended "uu-uw ewew-eww"; considerably lower, slower and more spaced than that of *A. morrisonia*, and with no buzzy end notes. Calls "chrr-r-r" and the like, similar to those of *A. morrisonia*.

**Habitat.** Broadleaf evergreen forest, moist deciduous forest, forest edge, secondary growth, and bamboo. Found at 245–2285 m in Nepal and 600–2000 m in Bhutan; 300–2100 m in India (foothills to highest summits in Assam); 900 m in Xizang; 440–2400 m in Myanmar.

**Food and Feeding.** Insects, nectar and berries, the last forming a large part of diet in Sept–Feb non-breeding period. Outside breeding season found in restless flocks of up to 20 individuals, usually joining mixed flocks, which may include other small babblers. Forages mostly in undergrowth and crowns of lower trees, occasionally on ground. Flocks move very quickly.

**Breeding.** Mar–Jul. Nest, built by both sexes, usually a neat and compact deep cup, rarely loosely woven and semi-transparent, made of dead bamboo or other leaves, fine grasses, fern fronds, fine fern roots, moss roots, fine black roots, bark fibre and tattered palm bark, sometimes plastered with spider web, lined with moss roots, rootlets, fine black roots, and black and dark brown fibres, placed 0.3–1.5 m above ground in bush, bamboo clump, rattan or underbrush. Clutch 2–5 eggs, usually 3–4 in Nepal and India, china-white to pinkish or reddish-tinged white, speckled or blotched with reddish-brown to purplish-red; incubation by both sexes, period 12 days. No information on nestling period.

**Movements.** Resident. Description as common winter visitor in Nameri National Park, in Assam (NE India), implies seasonal altitudinal movements, but this otherwise undocumented and improbable.

**Status and Conservation.** Not globally threatened. Generally uncommon to locally common in Nepal. Common in Bhutan in foothills and C & E valleys, with density near Zhengang of 1.4 territories/km of road at 1600–1900 m; present in Thrumshingla National Park. Common from Sikkim E to NE India, where present in Buxa Tiger Reserve (West Bengal), Eaglenest Wildlife Sanctuary and Namdapha and Mouling National Parks (Arunachal Pradesh), Balphakram National Park (Meghalaya), Barail Reserve Forest (Assam), and Nengping Wildlife Sanctuary and Dampa Tiger Reserve (Mizoram), and probably in other protected areas. Common in Myanmar. Locally common in restricted range in Xizang (S China).

**Bibliography.** Ali & Ripley (1948, 1971), Allen *et al.* (1999), Baqar & Sharma (2003), Beis (1947, 1950), Brand & Pawar (2004), Choudhury (2003), Cox (1987), Godwin-Austen (1870), Grimmett *et al.* (1998), Hopwood (1912), Hume & Macleay (1913), Hume & Oates (1889), Issakov & Issakov (1991), Issakov *et al.* (2000), Katti *et al.* (1992), Koelz (1954), Ludlow & Kinnear (1937, 1944), Martens & Eck (1995), Mayr (1938), Rasmussen & Anderson (1990), Ripley (1950), Robinson & Kloss (1919), Stresemann (1923c), Ticehurst (1935), Stanford (1935), Stanford & Mayr (1941), Stanford & Ticehurst (1938), Stevens (1933, 1938), Stevens *et al.* (1938), Stresemann & Henrichs (1940a), Suaragay & Joshua (1997), Ticehurst (1933), Yen Kwokying (1936), Zheng Zuoxin *et al.* (1983).

## 40. Mountain Fulvetta

### *Alcippe peracensis*

**French:** Alcippe bridé **German:** Malaialcippe **Spanish:** Fulveta Montana

**Taxonomy.** *Alcippe peracensis* Sharpe, 1887, Larut Range, Perak, Peninsular Malaysia. Formerly treated as conspecific with *A. grotei*. Two subspecies recognized.

**Subspecies and Distribution.**  
*A. p. annamensis* Robinson & Kloss, 1919 – SC & S Laos, E Cambodia and Vietnam (C & S Annam).  
*A. p. peracensis* Sharpe, 1887 – extreme S Thailand and Peninsular Malaysia.

**Descriptive notes.** 14–15.5 cm. Nominant race has crown slaty, grey extending slightly onto mantle, bold black lateral crownstreak; upperparts faintly rufescent-tinged drab olive-brown; largely whitish below, with very light buffish creamy brown wash on throat side, breast and flanks, and pale greyish olive-brown lower flanks and vent; iris red to dark brown; bill blackish-horn or greyish-horn to grey or plumbeous; legs pale fleshy brown or yellowish-brown to pale olive-brown. Differs from similar *A. morrisonia* in having crown slatier with bolder lateral stripes, upperparts drabber, underparts whitish. Sexes similar. Juvenile has

head and mantle duller grey than adult, lateral crownstreaks less distinct, duller above, bill greyish. Race *annamensis* has paler grey crown, nape and head side than nominate, less rich upperparts, paler and drabber below, with less buff-tinged wash on breast. Voice. Song in Indochina (race *annamensis*) "iti-iwu uwi-u wheer wheer", "iti-iti-iwu wi-wui wheer wheer" and similar, reminiscent of song of *A. morrisonia* (with similar buzzy end notes) but somewhat faster and shorter; in Peninsular Malaysia (nominate) similar "iti-iwu-wi-wi" and "iti-iwu-u-wi", etc., but apparently with no buzzy end notes. Calls harsh "chrr-r-r" and the like, similar to those of *A. morrisonia*.

**Habitat.** Montane broadleaf evergreen forest and *Fokienia* forest, at 900–2100 m in Indochina, 760–2190 m in Peninsular Malaysia.

**Food and Feeding.** Insects. Found in pairs or in small parties of five or six individuals, often associating with other species, including other small babblers, in mixed flocks.

**Breeding.** Jan–Jun in Vietnam and Mar–Jun in Peninsular Malaysia. Nest a small cup made of dead leaves, moss and rootlets, placed 1.5–1.8 m above ground in bush, sapling or tangle of ferns, etc. Clutch 2 eggs, white or whitish, richly blotched and/or spotted with brown to dull brownish-crimson. No other information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Generally common across range. In Laos, very common in Dong Hua Sao National Biodiversity Conservation Area (NBCA), and present in Phou Xang He NBCA. In Vietnam, present in Thuong Da Nhim and Chu Yang Sin Nature Reserves (Da Lat Plateau, in S Annam); at latter site, density estimate of 3.26±0.87 birds/ha, yielding population estimate for the reserve of 28,190 individuals. In Peninsular Malaysia, common on Gunung Tahan and Bukit Fraser, and in Taman Negara National Park.

**Bibliography.** Collar (2006), Davidson *et al.* (1997), Deignan (1963), Delacour & Jabouille (1931a), Dickinson (1970), Eames (1995), Eichler (1989), Engelbach (1932), Evans *et al.* (2000), Hill *et al.* (2001), Lekagul & Round (1991), Madoc (1956), Medway & Wells (1976), Robinson (1928), Robinson & Kloss (1919a), Robson (2000), Robson *et al.* (1993a, 1993b), Showler, Davidson, Chanthavi Vongkhamheng & Khounmee Salivong (1998), Thewlis, Duckworth *et al.* (1996), Thewlis, Timmins *et al.* (1998), Timmins & Wilkinson (1996).

## 41. Black-browed Fulvetta

### *Alcippe grotei*

**French:** Alcippe de Grote **German:** Weißbauchalcippe **Spanish:** Fulveta Cejinegra  
**Other common names:** Eyebrowed Fulvetta

**Taxonomy.** *Alcippe nipalensis grotei* Delacour, 1936, Col des Nuages (16°11'N, 108°08'E), Annam, Vietnam.

Formerly treated as conspecific with *A. peracensis*. Race *eremita* poorly differentiated, and perhaps not worthy of recognition. Two subspecies currently recognized.

**Subspecies and Distribution.**  
*A. g. eremita* Riley, 1936 – SE Thailand.

*A. g. grotei* Delacour, 1936 – C & S Laos, E Cambodia and Vietnam.

**Descriptive notes.** 15.5–16.5 cm. Crown and nape are dull grey, shading to dull rufous-tinged brown on upperparts, upperwing and tail; blackish line beginning before eye as supercilium and trailing back as lateral crown-stripe onto nape; lores, postocular supercilial area, ear-coverts and cheek a shade paler grey than crown, shading on submoustachial area to whitish-buff chin and pale grey-tinged buffy throat and upper breast, becoming warmer and greyer on flanks, thighs and vent; lower mid-breast to centre of belly whitish; iris pale grey to brown, whitish weak broken eyering; bill blackish, yellowish-grey or bluish-horn; legs

greyish, reddish-grey or greyish-flesh. Differs from similar *A. peracensis* in larger size but distinctly shorter tail, brownish tinge on head and, especially, neck, more rufescent upperparts, only indistinct eyering. Sexes similar. Juvenile is warmer above and with browner head than adult. Race *eremita* is slightly greyer above than nominate. Voice. Song "yu-chi-chiwi-chu-woo", "yu-uwii-iu-woo", "yu-uwii-uw-woo", "yu-uwii-uw-uw-woo", "yu-yui-yui-uw-uw-uw-uw" and similar, like that of *A. ptoicephala* but usually rises less at end. When alarmed, utters harsh rasping spluttering "wit-it-irrit", "wittitrit", "wittitrit", "err-ritritritrit", etc.

**Habitat.** Broadleaf evergreen and semi-evergreen forest, logged and secondary forest, and scrub, at up to 1200 m.

**Food and Feeding.** Presumably small invertebrates and some vegetable matter; strangler figs reported, although possible that insects in fruit were the target. Usually found in small or medium-

sized parties, often in association with other species, including other babblers; often forms nucleus of mixed feeding flocks. Forages in middle storey and undergrowth.

**Breeding.** Feb–Jul in Vietnam. Nest a lightly built cup attached to stems of overhanging fern 1 m above ground. Clutch 3 eggs. No further information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Common across range. Abundant in Xe Pian National Biodiversity Conservation Area (NBCA), Dong Hua Sao NBCA and Phou Xang He NBCA, in Laos. Locally common resident in E Tonkin (in Cuc Phuong National Park), N & C Annam (Bach Ma National Park) and Cochinchina (uncommon in Nam Bai Cat Tien National Park), in Vietnam; present in many other protected areas (although currently listed under *A. peracensis* in certain publications, making enumeration impossible). First confirmed records in Cambodia in 2002.

**Bibliography.** Collar (2006), David-Beaulieu (1932), Davidson *et al.* (1997), Delacour & Jabouille (1931a), Duckworth & Hedges (1998), Eames *et al.* (2001), Engelbach (1932), Lê Manh Hùng *et al.* (2002), Lê Xuân Canh *et al.* (1997), Robson (2000), Robson *et al.* (1993b), Showler, Davidson, Chanthavi Vongkhamheng & Khounmee Salivong (1998), Thewlis, Duckworth *et al.* (1996), Thewlis, Timmins *et al.* (1998), Timmins & Trinh Viet Cuong (1999).

## 42. Brown-cheeked Fulvetta

### *Alcippe poioicephala*

**French:** Alcippe à joues brunes **German:** Graukopfalcippe **Spanish:** Fulveta Cariparda  
**Other common names:** Common/Grey-eyed Fulvetta; (Nilgiri) Quaker Babbler (*poioicephala*)

**Taxonomy.** *Thimalia* [sic] *poioicephala* Jerdon, 1841, Coonoor Ghat, Nilgiri Hills, India. Has sometimes been considered conspecific with *A. pyrrhoptera*. Races in peninsular India (nominate and *brucei*), with somewhat different songs from those of other races, considered possibly to represent separate species. Eight subspecies recognized.

**Subspecies and Distribution.**

*A. p. brucei* Hume, 1870 – C & S India.

*A. p. poioicephala* (Jerdon, 1841) – Western Ghats, in W India.

*A. p. fusca* Godwin-Austen, 1877 – E Bangladesh and NE India (S Assam) E to N, NW & NC Myanmar.

*A. p. phayrei* Blyth, 1845 – SW Myanmar (E to R Irrawaddy).

*A. p. haringtoniae* E. J. O. Hartert, 1909 – E Myanmar and NW Thailand.

*A. p. alearis* (Bangs & Van Tyne, 1930) – S China (SE Yunnan), N & C Laos, N Vietnam (W Tonkin) and N Thailand.

*A. p. karenii* Robinson & Kloss, 1923 – SE & S Myanmar (S to N Tenasserim) and adjacent W Thailand.

*A. p. davisoni* Harington, 1915 – extreme S Myanmar (S Tenasserim) and N peninsular Thailand.

**Descriptive notes.** 16.5 cm; 17–23 g. Relatively large “nun-babbler” with greyish-buff head side, distinctly buff underparts; lacks white eyering. Nominative race has crown dull, slightly brown-tinged grey, shading to dull rufous-tinged brown on upperparts, with stronger chestnut-brown on upperwing and tail; lores, superciliary area, ear-coverts, cheek and neck side a shade paler than crown; chin, submoustachial area and underparts very pale buffy tan, belly whitish-buff, flanks buffish-tan; iris dull white to greyish-brown, sometimes brown; upper mandible blackish-horn to dark grey, lower mandible greyish or bluish;

legs greyish-brown to flesh-pink. Sexes similar. Juvenile has upperparts, edges of wings and tail browner, iris slate-grey, gape and mouth bright yellow, paler parts of bill yellowish. Races differ mainly in tone of plumage: *brucei* is slightly larger and paler overall than nominate, crown and nape mid-grey, head side, upperparts, underparts and wing fringes paler, tail not quite so dark; *fusca* has crown and nape slightly darker than previous, upperparts intermediate in tone between previous and nominate (lacking grey on back); *phayrei* is very like previous, but slightly colder above and below; *haringtoniae* has upperparts somewhat darker and richer than last, more rufous-tinged (approaching nominate), crown similar (pronounced crownstripes), head side and underparts richer; *alearis* is very like last above, but (apart from crown) very slightly more greyish-olive, lateral crownstripes extending forward to bill base (but extremely faint), head side duller and greyer, underparts slightly less rich buff, wings duller; *karenii* is roughly intermediate between *haringtoniae* and *phayrei*, with indistinct crownstripes; *davisoni* resembles last but with even less distinct crownstripes, and upperparts slightly darker. **VOICE.** Sings with repeated pleasant phrases of spaced, fairly even notes, which usually rise at end, “chu-uwí-uwí-uwí”, “i-chíwi-uwí-uwí”, “yí-chíwi-uwí-uwí” and similar, sometimes more slurred “ch’uwí-u-uwí-uwí”; songs of *brucei* and nominate have been described as having first few notes shorter than rest and rising slightly and last ones rising again slightly, with beginning and ending softer, e.g. “tu-wi-twee-tuu-twee-túúwée”, with some versions more drawn-out, some faster, and most ending on short downslur; songs of *fusca* similar but descend only slightly and then ascend strongly, the strophe tending upwards, e.g. “tú-tú-tú-tú-twee-túúwée”. Calls with harsh buzzy spluttering rattles when agitated, e.g. “wit-irrrr”, “witt-witt”, “witch-tittittit” and “whi-chirru”, also higher “whi-shihhihi”.

**Habitat.** Bushes and small trees in evergreen and mixed moist deciduous forest, teak, secondary growth, sholas, mixed bamboo-jungle, scrub, occasionally gardens. At 855–2100 m (up to 1000 m in E); in peninsular India; foothills to 1000 m in Bangladesh; 520 m in China; up to 1520 m (mainly below 1200 m) in SE Asia.

**Food and Feeding.** Ants and other insects; also nectar, particularly of *Erythrina*. Usually found in parties of 6–10 individuals, sometimes up to 20 or more. Forages in middle storey and undergrowth but also ascends to canopy; often 9 m above ground. Often forms nucleus of mixed-species feeding flocks.

**Breeding.** Jan–Nov in India, Mar–Sept in Bangladesh and Jan–Sept in SE Asia. Nest a roughly built compact deep cup, sometimes almost cone-shaped, made of green moss, dead leaves, grasses, grass roots, moss roots, rootlets, plant fibres and fine twigs, sometimes plastered with cobweb, lichen or wool, lined with black moss roots, fern roots, and rootlets, placed usually 0.6–1.8 m (sometimes 3 m) above ground in bush, sapling, bamboo or fern. Clutch 2–3 eggs, white to pale pink, with blotches, smudges and streaks of reddish-brown to purple-black and clouds of pale grey to inky-purple; incubation by both sexes. No other information.

**Movements.** Resident; described as a local migrant in Kaziranga National Park, in India, but this not substantiated by other evidence.

**Status and Conservation.** Not globally threatened. In India, common in W Mysore S to W Tamil Nadu; locally very common in hills of peninsular India; uncommon in Kaziranga and Nameri Na-

tional Parks (Assam); common in Khasi and Cachar Hills (Nagaland and Manipur), and present in *Ilampá Tiger Reserve* (Mizoram). Common at least locally in Bangladesh. Locally common in limited range in China. Generally common in SE Asian range; very common in Myanmar, common in Thailand, including in Doi Chiang Dao Wildlife Sanctuary (in NW), Khao Yai National Park (in NE) and Kaeng Krachan National Park (in W); present in Nam Kading National Biodiversity Conservation Area, in Laos; present in Ba Be National Park, in N Vietnam, and in five protected areas in the Annamese Lowlands Endemic Bird Area.

**Bibliography.** Ali & Ripley (1972), Atturi *et al.* (2000), Bangs (1921), Barua & Sharma (1999, 2005), Birand & Pawar (2004), Chasen (1939), Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paolai (1960, 1962), Collar (2006), Cox *et al.* (1992), David-Beaulieu (1944), Davidson (1998), Deignan (1963), Delacour & Jabouille (1931a), Dickinson (1970), Duckworth *et al.* (1998), Eames *et al.* (2001), Grimmer *et al.* (1998), Hill (2000), Hopwood & Mackenzie (1917), Hume & Davison (1878), Hume & Oates (1889), King & Han Lianxian (1991), Lê Manh Hùng *et al.* (2002), Lekagul & Round (1991), Mayr (1938), Medway & Wells (1976), Meyer de Schauensee (1984), Nguyễn Đức Tú *et al.* (2001), Oates (1883), Rasmussen & Anderson (2005), Robinson (1928), Robson (2000), Showler, Davidson, Khounmee Salivong & Khamkhoun Khounboline (1998), Smith *et al.* (1943), Smythies (1986), Stanford (1935), Stanford & Mayr (1941), Stanford & Ticehurst (1930), Stresemann & Heinrich (1940a), Ticehurst (1933), Tizard *et al.* (1997), Wiles (1980), Yen Kwokying (1936), Zacharias & Gaston (1993).

## 43. Brown Fulvetta

### *Alcippe brunneicauda*

**French:** Alcippe brun **German:** Braunschwanzalcippe **Spanish:** Fulveta Parda  
**Other common names:** Malaysian Fulvetta

**Taxonomy.** *Hyloterpe brunneicauda* Salvadori, 1879, “Ayer Manchor”, a waterfall 10 kilometres from Padang Panjang (0°29' S, 100°22' E) on the road to the Padang Highlands, Sumatra.

Several races proposed, including *eriphaea* (Borneo), but differences trivial or undetectable in large samples. Monotypic.

**Distribution.** S Thailand, Peninsular Malaysia, Sumatra and Batu Is, N Natunas and Borneo.

**Descriptive notes.** 14.5–15 cm; 14.5–16 g. Nondescript “nun-babbler”, plain head without lateral crownstripes. Forehead, crown and nape are drab greyish mid-brown, head side paler and greyer, upperparts rather warm-tinged mid-brown, slightly more rufous-chestnut on rump and uppertail-coverts; upperwing blackish-brown on inner webs, outer fringes much paler rufescent brown; lores and submoustachial area greyish mixed with dull whitish; throat whitish, washed pale brown, lower throat side and wash across breast pale greyish-brown, tinged pinkish or creamy, belly whiter, breast side and flanks pale greyish-

brown, warm-tinged on lower flanks and thighs, vent whitish-brown; iris grey to dark brown; bill grey to dark brown, lower mandible often paler grey-brown; legs pale lavender to brown. Sexes similar. Juvenile presumably resembles adult. **VOICE.** Song a rather slow, measured, high-pitched and slightly undulating “hi-tu-tu ti-tu ti-tu”, “hi-tu hi-tu hi-tu” and “do-di-do-di-do-di-do” or descending “hi-tu-tu ti-tu ti-tu” and similar, repeated after rather long intervals. Calls with rather stressed “whit” notes and short harsh rattles.

**Habitat.** Primary evergreen forest, older secondary forest, overgrown forest clearings, rubber and *Albizia*, lightly logged forest; often close to streams. Up to 900 m in Thailand and to 760 m in Peninsular Malaysia; to 1000 m in Sumatra; generally to 1200 m, rarely 1430 m, in Borneo.

**Food and Feeding.** Insects, including beetles (Coleoptera), caterpillars, grasshoppers (Orthoptera); also red berries. Found in pairs or in small parties, often in company with other species in mixed flocks. Usually forages in lower middle storey, sometimes in low vegetation, by gleaning foliage.

**Breeding.** Apr–May in Thailand, Jun in Natunas and Sumatra; in Borneo, birds in breeding condition in May–Jul (Sabah), dependent juvenile in Aug, and adult feeding young in Feb. Nest reported in Thailand, but undescribed. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Generally uncommon to fairly common in continental range: fairly common in S Thailand; common in Taman Negara National Park, in Peninsular Malaysia. Uncommon in primary and secondary habitats in Sumatra, where present in Gunung Leuser and Bukit Tigapuluh National Parks; uncommon in Batu Is. Widespread in lowland mixed dipterocarp forests in Borneo, and common in Sabah, including in Danum Valley Conservation Area and on Mt Kinabalu; commonest bird species on Mt Penrissen, in Sarawak, and frequent in Berau district forest, in E Kalimantan; present in Similajau National Park (Sarawak) and Tanjung Puting National Park (S Kalimantan), and common in Gunung Niut Nature Reserve (W Kalimantan). A Sundaic lowland-forest species, thus highly susceptible to the extensive forest destruction throughout its range; preference for submontane forests and use of second growth, however, imply that it is not immediately at risk.

**Bibliography.** Anon. (2006d), Buij *et al.* (2006), Butchart & Stattersfield (2004), Chasen (1939), Chasen & Hoogerwerf (1941), Collar *et al.* (2001), Danielsen & Heegaard (1995), Deignan (1963), Duckworth & Kelsh (1988), Duckworth *et al.* (1997), Eames (2005), Holmes (1996), Johns (1989), Lekagul & Round (1991), van Marle & Vooijs (1988), Medway & Wells (1976), Nash & Nash (1988), Oberholser (1932), O’Brien & Kinnaird (1996), Priemé & Heegaard (1988), Robinson (1928), Robson (2000), Sheldon *et al.* (2001), Smythies & Davison (1999), Stattersfield & Capper (2000), Thompson (1966), Wilkinson, Dutton & Sheldon (1991), Wilkinson, Dutton, Sheldon, Darjono & Noor (1991).

## 44. Javan Fulvetta

### *Alcippe pyrrhoptera*

**French:** Alcippe de Java **German:** Rotrückenalcippe **Spanish:** Fulveta de Java

**Taxonomy.** [Apothera], *pyrrhoptera* Bonaparte, 1850, Java.

Has been treated as a race of *A. poioicephala*. Monotypic.

**Distribution.** W & C Java.

**Descriptive notes.** 14.5–15 cm. Dull chestnut and buff “nun-babbler”. Has crown to back dull chestnut-brown, very faint darker lateral crownstripes from above lores to nape, colour intensifying to rufous-chestnut on rump and uppertail-coverts, upperwing-coverts and wing fringes, tail deep warm brown with dark rufescent-chestnut outer fringes, particularly towards base; lores buffish, cheek and ear-coverts pale brownish-tan with whitish spots, throat pale to whitish-buff, richer on

Wildlife Sanctuary. Uncommon in China. Generally fairly common to common in SE Asian range: common in Myanmar, although uncommon in Natmoutang National Park; common in Nakai-Nam Theun National Biodiversity Conservation Area, in Laos. Fairly common in Fan Si Pan National Park and present in Vu Quang Nature Reserve, in Vietnam.

**Bibliography.** Ali & Ripley (1972), Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paolai (1960, 1962), Choudhury (2003), Davidson (1995), Delacour & Jaudouin (1984), Dowell *et al.* (1997), Eames *et al.* (2001), Evans & Timmins (1998), Grimmett *et al.* (1998), Harington (1909, 1914a), Hopwood & Mackenzie (1917), Huang Qiang, Deng Heli & Mao Ke (1995), Huang Qiang, Huang Yongzhao & Deng Heli (1993), Hume & Davison (1878), Hume & Oates (1889), King & Han Lianxian (1991), Kinnear (1929), La Touche (1923), Lee Kwok Shing *et al.* (2006), Oates (1980), Rasmussen & Anderton (2005), Riley (1926), Ripley (1952), Robson (2000), Singh (1995), Smith *et al.* (1940, 1943), Smythies (1986), Spierenburg (2005), Stanford & Mayr (1941), Stanford & Ticehurst (1938), Stresemann & Heinrich (1940a), Stuart Baker (1893), Tan Yaokuang & Cheng Tsohsin (1964), Thet Zaw Naing (2003), Tordoff, Lê Manh Hùng *et al.* (2002), Tordoff, Lê Trong Dat *et al.* (2001), Uchida & Kuroda (1916), Wang Zhijun & Wei Tianhao (1983), Wu Zhikang *et al.* (1986), Yen Kwokying (1934b, 1936).

## 47. Dusky Fulvetta

### *Schoeniparus brunneus*

**French:** Alcippe de Gould **German:** Rotkopfalcippe **Spanish:** Fulveta de Gould  
**Other common names:** Brown-capped/Brown-eared Fulvetta, Rufous/Rufous-headed Fulvetta, Gould's Fulvetta/Nun-babbler

**Taxonomy.** *Alcippe brunnea* Gould, 1863, Taiwan.

Genus usually merged into *Alcippe*. Suggested as forming a superspecies with *S. dubius*, and often considered conspecific, but the two occur sympatrically in China and differ morphologically. Five subspecies recognized.

**Subspecies and Distribution.**

*S. b. olivaceus* (Styan, 1896) – SC China (C & E Sichuan E to S Shaanxi, W Hubei and N Guizhou).  
*S. b. weigoldi* Stresemann, 1923 – Red Basin of Sichuan (China).

*S. b. supercilialis* (David, 1874) – SE China (E Guangxi E to F Hunan, SE Anhui, SW Zhejiang, N Fujian and N Guangdong).

*S. b. argutus* (E. J. O. Hartert, 1910) – Hainan I.

*S. b. brunneus* (Gould, 1863) – Taiwan.

**Descriptive notes.** 13–15 cm; 15–23 g. Nominative race has forehead to rump, upperwing and tail dull rufescent brown, long, broad blackish lateral crownstripe from above eye to rear nape side; lores and supercilium drab greyish-brown, ear-coverts and area behind them buffy grey; throat and central belly whitish, submoustachial area similar but feathers flecked dark greyish-brown; breast and upper flanks greyish-buff, shading to dirty greyish-brown on lower flanks, thighs and vent; iris brownish-reddish; bill black to dark brown; legs yellowish to yellowish-grey, sometimes tinged pink. Distinguished from *S. dubius* by very different facial appearance, with supercilium and neck side grey and ear-coverts buffy grey. Sexes similar. Juvenile is presumably as adult. Race *olivaceus* is paler on head, with less rufescence on forehead, weaker crownstipes, slightly ochraceous lower flanks to vent; *weigoldi* has mid-crown and nape darker, throat and mid-belly clearer white, breastband very pale; *supercilialis* has more rufescent upperparts with less obvious dark fringes of crown feathers, paler head side, more contrasting blackish submoustachial area, whiter throat and mid-belly, paler breast, very faint streaking on throat and breast, warmer-coloured lower flanks to vent; *argutus* is like last, but lores and ear-coverts slightly paler, bill slightly thinner. **Voice.** Song on Emei Shan (Sichuan) delivered in hurried, loud, shrill, nervous phrases of 4–5 notes, “wi wi-wi-wi-uu”, “uu wi-wi-wi-chuu”, “yu wi-wi-wi-uu” and the like, repeated every 7–8 seconds; similar to songs of *S. dubius* and *S. rufogularis*. Rather low “jurt” calls repeated by foraging birds.

**Habitat.** Broadleaf evergreen forest, grass-jungle, at 600–1700 m in China; mainly 1525–1830 m in Taiwan (elevation limits in N Taiwan 40–1590 m).

**Food and Feeding.** Insects, snails and seeds found in stomachs. Feeds on or near ground, skulking, in small parties; seen to move under leaf litter to forage.

**Breeding.** Apr–Jun. Nest a loose dome or semi-dome, with entrance at upper part, made of leaf fibres, dead leaves (including those of *Miscantheus*) and grass, lined with dry grass, placed 0.1–2.5 m above ground in bush. Clutch 4–5 eggs, in Taiwan clutch size given as 2–3; white (Taiwan) to greenish-white, blotched or mottled/clouded with various shades of brown over spots of pale lilac and grey/blue-grey, sometimes with dark brown specks and short lines. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common in S China, where recently recorded at 15 (28%) of 54 sites surveyed (52 of which are nature reserves); widespread in wooded hills in Guangdong. Common in Taiwan.

**Bibliography.** Caldwell & Caldwell (1931), Cheng Tsohsin (1987), Cheng Tsohsin *et al.* (1963), Dowell *et al.* (1997), Hachisuka & Udagawa (1950, 1951), Huang Qiang *et al.* (1995), King (1989a), King & Liao Weiping (1989), King & Zheng Guangmei (1988), Kleefisch (1995), Koh Chaonien & Lee Peifen (2003), La Touche (1899, 1925–1930), Lee Kwok Shing *et al.* (2006), Lewthwaite (1996), Liu Kazhi *et al.* (1994), Meyer de Schauensee (1984), Ogilvie-Grant (1906), Severinghaus & Blackshaw (1976), Smith & Yu Hontsen (1992), Stresemann (1923c), Viney *et al.* (1994), Wu Zhikang *et al.* (1986), Yen Chungwei (1990), Yen Kwokying (1934a, 1936), Zheng Zuoxin & Qian Yanwen (1973).

## Genus RHOPOCICHLA Oates, 1889

### 48. Dark-fronted Babbler

#### *Rhopocichla atriceps*

**French:** Timalie à tête noire **German:** Kapuzentimalie **Spanish:** Timalí Frentinegro  
**Other common names:** Black-headed/Black-fronted Babbler

**Taxonomy.** *Brachypteryx*, *atriceps* Jerdon, 1839, the Wynad, south-west India.

Has been placed in genus *Alcippe*. Four subspecies recognized.

**Subspecies and Distribution.**

*R. a. atriceps* (Jerdon, 1839) – Western Ghats (from Belgaum S to Palghat Gap), in SW India.

*R. a. bourdilloni* (Hume, 1876) – SW India (Kerala and W Tamil Nadu).

*R. a. siccata* Whistler, 1941 – C Sri Lanka.

*R. a. nigrifrons* (Blyth, 1849) – SW Sri Lanka.

**Descriptive notes.** 13 cm; 16–17 g. Compact square-tailed brown-backed babbler with variably dark head, yellowish eye and whitish underparts. Nominative race has head (down to moustachial line, cheek and ear-coverts) blackish-brown, upperparts, upperwing and tail warm olive-brown; chin, throat and submoustachial area pure white; breast, upper flanks and belly white, tinged grey, lower flanks, thighs and vent dull ochrous-buff; iris pale yellow; upper mandible dark horn-brown, lower mandible pale greyish-flesh; legs pinkish-grey. Sexes similar. Juvenile has black of head side less sharply defined, edges of wings

and tail rustier. Race *bourdilloni* has crown, nape, lores and cheek sooty brown, more extensive and richer ochre on lower underparts; *siccata* has colour of upperparts extending onto head as far as mid-crown, breast and central belly cleaner white (as throat); *nigrifrons* is like previous but richer-toned above. **Voice.** Song, if any, unreported. Utters sundry squeaks, including excited clattery rattle, e.g. “kt’t’t’t”, kt, kt’t’t”, in short bursts and long series, and a harsh, rather subdued “chur-chur-r” when on move in flock; alarm a rattling “chur-r”.

**Habitat.** Undergrowth and clearings in forest, secondary growth, overgrown plantations, sholas, thickets near streams, dense and marshy jungle, cardamom cultivation, scrub, reedbeds, bamboo-jungle and cane brakes in dank ravines; lowlands to 1800 m, mainly above 600 m in India, but to 2100 m in Sri Lanka.

**Food and Feeding.** Insects. Found in parties of up to 12 or more individuals (but mean group size in one study only 3–3), often in association with other babblers. Seldom ascends more than 1–2 m above ground.

**Breeding.** Most months but mainly Mar–Jul in India, and in all months (with least activity Jun–Sept) in Sri Lanka. Nest a loose dome made of dry bamboo or other leaves, grasses and twigs, lined with black rootlets and grasses, placed 0.6–1.2 m above ground in thick shrub, brambles, grass, reeds or weeds; also builds “cock nests”, very loosely and untidily made balls of bamboo leaves, unlined and usually in full view, not used for breeding although up to four birds may roost in them (three or more such nests may be found close together, the product of up to 4–5 birds); breeding nest may be used as a family roost for some time after young fledged. Clutch 2–3 eggs, usually 2, white to greyish-white or fleshy white, with little spots of reddish-brown and purplish-red, sometimes with underlying specks of bluish-grey. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common in India, where present in Mudumalai National Park (Tamil Nadu); in surveys in 1973–1997 in Western Ghats, found to be mostly common to abundant in 22 areas, including eight protected areas, namely Sultan’s Battery, Silent Valley, Parambikulam, Munnar, Periyar East, Periyar West, Tenmalai and Agastiamalai. Widespread in lowlands and hills in Sri Lanka, and common in Sinharaja Forest Reserve.

**Bibliography.** Ali & Ripley (1971), Belts (1935), Gokula & Vijayan (1997), Grimmett *et al.* (1998), Harrison (1999), Henry (1998), Hume & Oates (1889), Kotagama & Fernando (1994), Kotagama & Goodale (2004), Legge (1880), Phillips (1978), Rasmussen & Anderton (2005), Wait (1925), Yen Kwokying (1936), Zacharias & Gaston (1993, 1999).

## Genus DUMETIA Blyth, 1852

### 49. Tawny-bellied Babbler

#### *Dumetia hyperythra*

**French:** Timalie à ventre roux **German:** Rotbauchtimalie **Spanish:** Timalí Ventrirrúfo  
**Other common names:** White-throated Babbler; Rufous-bellied Babbler (*hyperythra*)

**Taxonomy.** *Timalia hyperythra* Franklin, 1831, Ganges between Calcutta and Benares (Varanasi), India. Proposed race *abuensis* (from W India) considered inseparable from *albogularis*. Three subspecies recognized.

**Subspecies and Distribution.**

*D. h. hyperythra* (Franklin, 1831) – N, C & E India and S Nepal.

*D. h. albogularis* (Blyth, 1847) – W & S India.

*D. h. philipsi* Whistler, 1941 – Sri Lanka.

**Descriptive notes.** 13 cm; 10–15 g. Striking small babbler, ochrous-brown above and buffy rufous below, with longish graduated tail. Nominative race has forehead to mid-crown rusty brown, slightly darker lateral crownstripe, hinderown to back dull ochrous-brown, slightly paler on uppertail-coverts; upperwing and tail mid-brown; lores, supercilium and cheek buffy rufous with slight grey tinge; chin, throat, submoustachial area, neck side and underparts rich buffy rufous; iris hazel to creamy white; bill pale brown, paler lower mandible; legs pale yellowish to dusky-tinged yellowish-flesh. Sexes similar. Juvenile lacks rusty tinge

on forehead, underparts duller and paler. Race *albogularis* has white oval patch from chin to upper breast, small white patch on central belly, much paler head side than nominate, buffy rufous slightly paler, *philipsi* is like previous, but paler rufous below, with larger white patch on belly, larger bill, white on supercilium and ear-coverts. **Voice.** Clear whistling song of 7 notes, described also as pleasant, quick, thin, piercing, high-pitched but sharply descending whistling, first part very like song of Indian Bushlark (*Mphala erythraea*), latter part resembling canary-like notes of “sunbird”.

the two running into each other, "passi-yú" or "ssiiú", then "tit-ut-switt(-it)", "whit-ut" or "whit-it-it". Contact notes rather feeble but sharp staccato cheeping, "tit", "twit" and "tut"; varied occasionally by harsher twittering, especially when alarmed; also a soft "tack-tack", like sound made when two pebbles tapped together.

**Habitat.** Open wooded country and scrub, grassland dotted with shrubs, bamboo clumps, thorn-scrub, wasteland near forest, deciduous and mixed-deciduous scrub-jungle and forest; avoids pure evergreen stands. Has bred in compounds. Lowlands to 915 m, locally to 1800 m in S India; 75–305 m in Nepal.

**Food and Feeding.** Mainly insects, in Sri Lanka larvae and minute beetles (Coleoptera) noted; nectar of coral trees (*Erythrina*) and *Salmalia* also taken. Found in loose flocks of 5–12 individuals; moves through grass and feeds on ground among dead leaves, foraging in manner of a fulvetta.

**Breeding.** Jan–Oct; multi-brooded. Nest a loose or neat dome, with side entrance (sometimes towards top), made of coarse grasses, dead bamboo or other leaves, rarely paper shavings, scantily lined with fine grasses, grass roots, fern stems, hair and fine fibres, placed on ground among dead leaves or near ground among bamboo roots, grass or weeds, or in shrub, or thorny bush overgrown with creepers, usually below 1 m, sometimes up to 2 m above ground; in compound in India, once

nested at foot of cactus plant, once in *Jasminum* bush, both close to a house wall. Clutch 2–4 eggs, usually 3–4 in India, 3 in Sri Lanka, white or pinkish-white with speckles, spots, blotches or streaks of reddish-brown to purplish-grey; incubation period 13 days; nestling period 18 days maximum. Brood parasitism by Banded Bay Cuckoo (*Cucumantis sonneratii*) reported.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare and local in Nepal. Generally common in India, where seen intermittently in Rajaji National Park and common in Dudhwa National Park (both Uttar Pradesh), but rare in Dehra Dun valley (Uttaranchal), and uncommon in Ranthambhore Sanctuary (Rajasthan); in surveys in 1973–1997 in Western Ghats, found in 17 areas, including seven protected areas, namely Sultan's Battery, Silent Valley, Parambikulam, Munnar, Periyar East, Periyar West and Agastiamalai. Rare but widespread in Sri Lanka, although common in Uda Walawe National Park. Probably now extinct in Bangladesh.

**Bibliography.** Acharya (1951), Ali & Ripley (1971), Grimmett *et al.* (1998), Harrison (1999), Henry (1998), Inskipp & Inskipp (1991), Javed & Rahmani (1998), Kotagama & Fernando (1994), Legge (1880), Pandey *et al.* (1994), Phillips (1978), Rasmussen & Anderton (2005), Sankar *et al.* (1993), Singh (2000), Vyas (1999), Zacharias & Gaston (1993, 1999).

## PLATE 5

## Family TIMALIIDAE (BABBLERS) SPECIES ACCOUNTS

### Genus *STACHYRIS* Hodgson, 1844

#### 50. Sooty Babbler

#### *Stachyris herberti*

French: *Amalite de Herbert*

German: *Laosbuschmalie*

Spanish: *Timali de Herbert*

Other common names: Laos Dusky Babbler

**Taxonomy.** *Nigravis herberti* Stuart Baker, 1920, Ban Sao, Thailand; error = Ban Lak Sao (18°11' N, 104°58' E), Laos.

Somewhat different in plumage from congeners, and sometimes placed in a genus of its own, *Nigravis*, but general consensus is that such treatment is unnecessary. A recently discovered babbler (with white-spangled breast and white rear ear-coverts) from S China may represent a well-marked race of present species or a new but closely related species. Monotypic.

**Distribution.** C Laos and C Vietnam (C Annam).

**Descriptive notes.** 16 cm, 29 g. Sooty-brown babbler with paler throat, and pale bill and eyering. Forehead, crown, lores, nape and line under eye, cheek and ear-coverts a shade darker, upperwing and tail blackish; chin whitish, shading to pale mouse-brown on throat, and smoky brown on neck side.

connecting around rear of ear-coverts to smoky-brown supercilium; iris brown, pale bluish-grey orbital ring; bill pale blue-grey to pinkish-grey; legs brown. Sexes similar. Juvenile is more uniformly brownish, lacks obvious eyering. **VOICE.** Song apparently unreported. Very soft, repeated "tip" and "tu-tip" and subdued metallic "cheet cheet cheet" contact notes uttered by foraging flocks; short, hard "wittitit" when agitated.

**Habitat.** Stunted but closed-canopy lowland broadleaf evergreen forest on limestone in vicinity of steep cliffs and outcrops, also fairly open vegetated karst; to at least 610 m.

**Food and Feeding.** Small invertebrates; those reported include a harvestman (Opiliones), caterpillar (Lepidoptera), possibly a bug (Hemiptera), stick-insect (Phasmatodea) and several small snails, which were hammered against rocks. Forages in single-species groups of 4–20 or more individuals, but sometimes joins bird waves. Commonly moves over surface of karst limestone, climbing vertically on rock faces, sometimes disappearing into holes, or in understorey of associated vegetation; also enters canopy layer, when frequently searches among vines and lianas, running rapidly along them with body held flat and tail slightly fanned.

**Breeding.** Mar and May in Laos. Only nest reported was placed on ledge in hollow in tree-enclosed karst, on rock face 2.5 m high, fibrous and leafy nest material being brought by two birds (and a third bird seen). No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Annamese Lowlands EBA. Fairly common in Vietnam at a single locality, Phong Nha Nature Reserve, in C Annam; locally common over a fairly wide area in Laos. Because the karst hills on which its habitat grows are so difficult to penetrate, it is relatively secure; forest destruction at foot of karst, however, may possibly remove an important habitat component, and this potential risk needs to be investigated. Present in Hin Namno, Khammouan Limestone and Nam Kading National Biodiversity Conservation Areas, in Laos.

**Bibliography.** Anon. (2006d), Butchart & Stattersfield (2004), Collar *et al.* (2001), Delacour & Jabouille (1931a), Duckworth *et al.* (1998), Eames (2001), Eames, Evc & Tordoff (2001), Eames, Lambert & Nguyễn Cu (1995), Kalyakin (2003), Nguyễn Cu *et al.* (2000), Robson (2000), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stuart Baker (1920, 1921), Thewlis *et al.* (1998), Williamson (1945).

## 51. White-bibbed Babbler

### *Stachyris thoracica*

**French:** Timalie à col blanc **German:** Weißbrust-Buschtimalie **Spanish:** Timali Cuelliblanco  
**Other common names:** White-collared Babbler, White-collared Tree-babbler

**Taxonomy.** *Pitta thoracica* Temminck, 1821, Mount Salak (6°42' S, 106°44' E), west Java.  
Two subspecies recognized.

**Subspecies and Distribution.**

*S. t. thoracica* (Temminck, 1821) – W Java.

*S. t. orientalis* Robinson, 1918 – C & E Java.

**Descriptive notes.** 18 cm. Large *Stachyris* babbler with chunky bill, dull chestnut with distinctive blackish throat and broad irregular-edged white breastband. Nominative race has entire plumage dull dark chestnut-brown, except for dark grey face (lores, cheek, ear-coverts), blackish chin and throat (slightly darker than ear-coverts), sometimes with short extension onto upper mid-breast, and broad white band across upper breast to lower neck side, lower edge of this band shifting unevenly to colour of remaining underparts and sometimes vaguely bordered with greyish; iris red, pale blue orbital skin; upper mandible slaty black,

lower mandible caerulean blue with distal half pale yellowish-horn; legs greenish-slate or bluish-slate. Sexes similar. Juvenile apparently undescribed; museum specimen with greyer throat may be immature. Race *orientalis* has dark grey crown to nape and blackish lower border of white breastband. **VOICE.** Song apparently undocumented. Call a continuous low rumbling, pulsating "chr'r'r'r'r'r'r'r", also shorter "chr'r'chr'r'chr'r'chr'r", and abrupt "chrrp".

**Habitat.** Undergrowth and dense thickets in broadleaf evergreen forest, to 1600 m.

**Food and Feeding.** Insects; cockroach egg sacs (Blattodea), grubs and caterpillars recorded. Forages in small groups in low forest vegetation, occasionally ascending vine-covered trees and entering thickets in gardens. Shy.

**Breeding.** Feb and Oct in W Java. Nest an open solid cup of roots and rattan leaf tendrils, placed not far above ground. Clutch 2–3 eggs, white. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Java and Bali Forests EBA. Uncommon in Gunung Gede-Pangrango National Park, in W Java.

**Bibliography.** Andrew (1985), van Balen (1992), Bartels (1901), Hoogerwerf (1948, 1949, 1950a), MacKinnon (1988), van Marle & Voous (1988), Nijman & van Balen (1998), Sody (1956), Stattersfield *et al.* (1998), Voous (1948), Vorderman (1886).

## 52. Black-throated Babbler

### *Stachyris nigricollis*

**French:** Timalie à gorge noire **German:** Schwarzkehl-Buschtimalie **Spanish:** Timali Gorginegro  
**Other common names:** Black-necked Babbler

**Taxonomy.** *Timalia nigricollis* Temminck, 1836, Borneo.  
Monotypic.

**Distribution.** S Thailand, Peninsular Malaysia, Sumatra and Borneo.

**Descriptive notes.** 15.5–16 cm; 18–31 g. Distinctive dark stout-billed babbler with rufous-chestnut upperparts and wings, black face and breast with white markings and dark grey belly. Lores and forehead are black, latter with fine white streaks, shading to dark olive-tinged grey on mid-crown to nape; short white postocular eyestripe, blackish-grey ear-coverts; upperparts dull rufous-chestnut (with fluffy lower back), upperwing and tail slate-grey with rufous-chestnut fringes; chin to breast black with narrow necklace of black-edged white feathers, broad but short white submoustachial streak; neck side and breast side to belly dark grey,

vent dark olive-chestnut; iris red, black eyelids; upper mandible black, lower mandible slaty with pale horn patch mid-way along; legs lead-grey to olive-black. Sexes similar. Juvenile is duller than adult, lacks white streaks on crown and white necklace, breast browner, underparts more sooty grey. **VOICE.** Song a repeated series of spaced, deliberate, monotonous, rather weak-sounding piping notes, the first couple stressed, "pu-pu-pu-pu-pu-pu" or "too-too-too-too-too..." and faster "pupupupupupupupupup"; frequently accompanied by low churring from mate; also more convoluted series of rapidly repeated hollow notes, "puwut-puwut-puwut-puwut", "pwut-pwut-pwut-pwut-pwut" and "chu-chuwu-chu-chu-chu-chu", etc. Calls include harsh slow rattled "tchrrrr-rrt" and "chrrrr-tchrrrrrrrrrr", harsh descending "ti-tu-chu-chu" or "chi-chi-chew-chew", and high "tchi-tchi".

**Habitat.** Undergrowth and edge of primary and secondary evergreen forest, selectively and heavily logged forest, freshwater swamp-forest and peatswamp-forest, sometimes tidal swamp-forest in Borneo, also overgrown rubber plantations, edges of overgrown tree plantations, *Albizia*, and oil-palm (*Elaeis*) plantation scrub; seems much more numerous in logged forest and reverting plantations; occasional in riverine swamp-forest, tall and stunted kerangas. Lowlands to c. 460 m in SE Asia; to 1400 m (but usually lower) in Sumatra.

**Food and Feeding.** Invertebrates, including beetles (Coleoptera). Typically forages in low vegetation, gleaning from foliage.

**Breeding.** May–Jul in SE Asia; Apr–Aug and juvenile also in Sept in Borneo. Nest a dome with loose canopy of dry leaves and flat, circular base, made of fibrous material (strips broader and coarser when on ground, shorter and finer when higher up), lined with slender strands of blackish fibre, placed on or close to ground among dense undergrowth. Clutch 2 eggs, pure white. Brood parasitism by Hodgson's Hawk-cuckoo (*Cuculus fugax*) reported. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Generally uncommon to fairly common in mainland range, but extinct in Singapore. Common in lowlands of Borneo in disturbed areas: present in Similajau National Park (Sarawak) and common in Tanjung Puting National Park (S Kalimantan). Presumed uncommon in Sumatra, where present in Gunung Leuser, Bukit Tigapuluh and Way Kambas National Parks; common in last-named, and common in heavily logged areas and rubber jungle in Bukit Tigapuluh. A Sundic lowland-forest species, thus highly susceptible to the extensive forest destruction (including severe loss of peatswamp-forest) that continues throughout its range, although use of submontane forest implies that it is not immediately at risk. Nonetheless, numbers decline in response to fragmentation of lowland-forest habitat.

**Bibliography.** Anon. (2006d), Buij *et al.* (2006), Butchart & Stattersfield (2004), Chasen (1939), Collar *et al.* (2001), Danielsen & Heegaard (1995), Deignan (1963), Duckworth & Keish (1988), Duckworth *et al.* (1997), Johns (1989), Lambert & Collar (2002), Lekagul & Round (1991), van Marle & Voous (1988), Medway & Wells (1976), Nash & Nash (1988), Parroti & Andrew (1996), Robson (2000), Sheldon *et al.* (2001), Smythies & Davison (1999), Stattersfield & Capper (2000), Wilkinson, Dutton & Sheldon (1991), Wilkinson, Dutton, Darjono & Noor (1991).

## 53. White-necked Babbler

### *Stachyris leucotis*

**French:** Timalie oreillard **German:** Perhals-Buschtimalie **Spanish:** Timali Orejudo  
**Other common names:** White-eared Babbler/Tree-babbler

**Taxonomy.** *Timalia leucotis* Strickland, 1848, Malacca, Peninsular Malaysia.  
Three subspecies recognized.

**Subspecies and Distribution.**

*S. l. leucotis* (Strickland, 1848) – S Thailand and Peninsular Malaysia.

*S. l. sumatrensis* Chasen, 1939 – N & C Sumatra.

*S. l. obscurata* Mayr, 1942 – Borneo.

**Descriptive notes.** 14–15 cm; 26–29 g. Small, rather short-tailed, chunky babbler resembling *S. nigricollis*, but duller above, with fewer white markings and grey breast. Nominative race has crown greyish olive-brown, lores to area above eye buffy, continuing as (often broken) whitish supercilium breaking into white spots on black around rear of greyish ear-coverts; upperparts, including upperwing and tail, rufescent olive-brown, with bold pale rufous-buff tips on median and greater upperwing-coverts, tertials and secondaries; chin, submoustachial area and throat black, extending to join black behind ear-coverts, sharply demarcated from mid-grey underparts, sometimes with pale shaft streaks, browner on flanks and lower belly; undertail-coverts rufescent brown with broad buffy tips; iris brown to dark brown; upper mandible dark grey to black, lower mandible pale grey to plumbeous; legs olive-brown to light brown. Sexes similar. Juvenile is

On following pages: 54. Snowy-throated Babbler (*Stachyris oglei*); 55. Spot-necked Babbler (*Stachyris striolata*); 56. Grey-headed Babbler (*Stachyris poliocephala*); 57. Grey-throated Babbler (*Stachyris nigricollis*); 58. White-breasted Babbler (*Stachyris grammiceps*); 59. Crescent-chested Babbler (*Stachyris melanothorax*); 60. Chestnut-winged Babbler (*Stachyris erythroptera*); 61. Chestnut-rumped Babbler (*Stachyris maculata*).

**Food and Feeding.** Mainly insects, but only bush-crickets (Tettigoniidae) specified. Found in small single-species parties of up to 30 individuals (mean 11 on Mt Hahmun), but usual complement rarely exceeds six; commonly joins larger mixed flocks with strong representation of other

babblers, or associates with one other babbler species, e.g. *Macronus flavicollis* or *S. melanothorax*. Forages in undergrowth and middle stratum, typically at 3–5 m height, gleanings from leaves and vigorously probing decaying fronds and leaf tangles in relatively open understorey, sometimes hanging upside-down.

**Breeding.** Possibly in all months, but with peak in May–Jun (adults in body moult or full moult in Aug–Oct); fledging in Oct, and juveniles in Feb–Mar, Jul and Sept–Nov. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Java and Bali Forests EBA. Known from 19 sites, majority in W Java, with two in C Java and one in E Java. Patchily distributed but often common in appropriate habitat. In Gunung Halimun National Park (W Java), one of the commonest species in lowland forest in 1994, with densities as high as 4.3 birds/ha; relatively little such forest now remains, however, and species was uncommon to fairly common there in 2006. Appears to tolerate degree of forest disturbance: studies at Halimun suggest preference for areas with small-scale degradation and light-gaps, and more recent work implies possible adaptation to forest disturbance. Nevertheless, forest at low elevations in Java, including inside Gunung Halimun National Park, under considerable pressure. Recorded also in Ujung Kulon National Park and Gunung Gede-Pangrango National Park.

**Bibliography.** Anon. (1993, 2006d), van Balen *et al.* (2005), Butchari & Stattersfield (2004), Collar *et al.* (2001), Hoogerwerf (1950a, 1971), MacKinnon (1988), Nijman & van Balen (1998), Sodhi, Soh *et al.* (2005), Sody (1956), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Voous (1948).

## 59. Crescent-chested Babbler

### *Stachyris melanothorax*

**French:** Timalie perlée **German:** Perlwangen-Buschtimalie **Spanish:** Timali Perlado  
**Other common names:** Pearl-cheeked Babbler/Tree-babbler, Pearl-chested Babbler

**Taxonomy.** *Myiothera melanothorax* Temminck, 1823, Mount Gede (6°47' S, 106°59' E), west Java. Has sometimes been placed in genus *Macronus*. Plumage geographically variable, to greater extent than is reflected in current subspecific classification; on other hand, at least one authority prefers to merge *mendeni* and *albigula* with nominate. A further, undescribed race may exist on Bawean I, off NE Java. Five subspecies currently recognized.

#### **Subspecies and Distribution.**

- S. m. melanothorax* (Temminck, 1823) – W & C Java.
- S. m. mendeni* (Neumann, 1935) – Indramayu, in W Java.
- S. m. albigula* (Stresemann, 1930) – Mt Papandayan, in W Java.
- S. m. intermedia* (Robinson, 1918) – E Java.
- S. m. baliensis* (E. J. O. Hartert, 1915) – Bali.

**Descriptive notes.** 13 cm. Small, rather long-billed *Stachyris* babbler, ochrous-brown above, with rufous wings, pale below, with black crescent across breast. Nominative race has crown dull rufous-brown, nape to rump warm ochrous-brown, greater upperwing-coverts and primary coverts pale rufous-chestnut, primaries and secondaries edged paler rufous-chestnut, tail with rufous-chestnut tinge; side of face (lores, supercilium, ear-coverts, cheek) and neck side pale grey, blackish mark under ear-coverts; chin and throat creamy white, blackish crescent on upper breast, centre of breast creamy white, shading greyer below and to

buffish-ochre on belly, lower flanks, thighs and vent; iris brown; bill dark brown; legs brown. Sexes similar. Juvenile apparently undescribed. Race *albigula* is darker above than nominate, with paler grey ear-coverts and almost pure white throat; *mendeni* is colder olive-brown above, crown pale, throat as previous, grey on breast pale, and lower underparts with little buff-ochre tint; *baliensis* has throat light buff, breast rusty buff, slightly larger bill; *intermedia* is intermediate between nominate and previous, having mid-breast sandy buff and chin and throat white (not buff). **VOICE.** Song a quick rolling piping trill, "phr'r'r'r'r'r'r" or "puw'w'w'w'w'w" (recalling that of *S. erythroptera*), accompanied by harsh low churring calls (presumably from female), e.g. "tchrrrr't", "tr'r'r'r't" or "tchrrrr't".

**Habitat.** Dense thickets and thick scrub usually at forest edge, monsoon forest, wooded areas around villages; sea-level to 1500 m.

**Food and Feeding.** Spiders (Araneae) and insects. Forages in parties, occasionally associating with *S. thoracica* and *S. grammiceps*, and sometimes in bird waves. Uses feeding techniques typical of genus, such as investigating dead leaf tangles. Seen as high as c. 10 m in canopy.

**Breeding.** Recorded in all months except Jul (peak May–Jun in W Java). Nest a hollow dome with large side entrance near top, made of rattan, palm leaves, leaf ribs, rootlets, fibres and grass, placed close to ground. Clutch 2–3 eggs, white. Nests parasitized by Asian Drongo-cuckoo (*Surniculus lugubris*). No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Java and Bali Forests EBA. Generally common. Common in Gunung Gede-Pangrango National Park and present in Ujung Kulon National Park, both in W Java; present also in Alas Purwo National Park, in E Java.

**Bibliography.** Andrew (1985), Anon. (1993), van Balen (1992), Grantham (2000), Hoogerwerf (1947, 1950a, 1950b, 1971), Jany (1953), MacKinnon (1988), Nijman & van Balen (1998), Robinson & Kloss (1924a), Sody (1956), Stattersfield *et al.* (1998), Voous (1948).

## 60. Chestnut-winged Babbler

### *Stachyris erythroptera*

**French:** Timalie à ailes rouges **German:** Rotflügel-Buschtimalie **Spanish:** Timali Alirrojo  
**Other common names:** Red-winged Babbler/Tree-babbler

**Taxonomy.** [*Timalia*], *erythroptera* Blyth, 1842, Singapore.

Has sometimes been placed in genus *Macronus*. Five subspecies recognized.

#### **Subspecies and Distribution.**

- S. e. erythroptera* (Blyth, 1842) – extreme S Myanmar (S Tenasserim) and S Thailand, Peninsular Malaysia, Singapore and N Natuna Is.

*S. e. pyrrhophaea* (Hartlaub, 1844) – Sumatra, including Batu Is, Bangka and Belitung.

*S. e. fulviventris* (Richmond, 1903) – Banyak Is, off NW Sumatra.

*S. e. bicolor* (Blyth, 1865) – N Borneo (including Banggi I).

*S. e. rufa* (Chasen & Kloss, 1927) – S Borneo.

**Descriptive notes.** 12.5–13.5 cm; 10–16 g. Small *Stachyris* babbler, dull chestnut above, greyish on face and underparts, with thin dark bill and bluish eyering. Nominative race has crown and upperparts dull ochrous chestnut-brown, face (forehead, lores, supercilium, cheek and ear-coverts), throat, breast and flanks dark dirty grey, shading paler on mid-breast and becoming dull greyish-buff on belly and vent; iris red (including broad blue to violet orbital skin (dark brown); bill dark blue-grey or blackish; legs pale grey to grey-green; when singing, shows blue, pale blue-green or violet bare neck skin. Sexes similar.

Juvenile is paler brown above and paler grey below than nominate. Race *pyrrhophaea* is darker grey from upper breast to vent; *fulviventris* is darker slate on breast and head side, darker grey-buff belly to vent; *bicolor* has dark grey crown and nape, and similarly grey anterior underparts; *rufa* has richer chestnut upperparts. **VOICE.** Song a soft, mellow, quite quick, piping but variable whistle of 7–10 notes, "hu-hu-hu-hu-hu-hu", occasionally a faster tremulous "hu hu'u'u'u'u'u'u" or slow "chu hu-hu-hu-hu"; may be accompanied by low "chrrr" notes (presumably from female). Calls with harsh scolding "trrrrr-trrrrr..." and soft "wip" and "wit" contact notes.

**Habitat.** Primary evergreen forest and tall secondary evergreen forest, selectively logged forest, bamboo brakes, upland heath, coastal peatswamp-forest, inland and tidal swamp-forest, and landward edge of mangroves; also tree plantations, including eucalypts (*Eucalyptus*), *Gmelina* and *Albizia*. To 800 m in Thailand and Sumatra, reaching 1220 m in N Borneo (Sabah).

**Food and Feeding.** Insects, including small beetles (Coleoptera), stick-insects (Phasmida), black ants (Formicidae), plant-bugs (Hemiptera), locusts; some fruits taken. Typically in small groups, methodically foliage-gleaning in middle storey, examining lower surfaces of twigs, probing angles between petioles and stems of understorey plants, probing within clusters of dead leaves, pulling up dangling vegetation to investigate with bill.

**Breeding.** Dec–Sept in SE Asia, and Mar–Jul and Oct–Nov in Borneo; probably multi-brooded. Partly a social breeder; nest built by both sexes, but observations of up to four birds building single nest. Nest a loose or quite compact dome with side entrance, made of dead bamboo or other leaves, dry grasses, leaf skeletons and twigs, caulked with moss, loosely lined with fine rootlets and fibres, placed 0.4–5 m above ground in tangled creepers, between creepers and sapling, or in sapling, thorny rattan or bush. Clutch 2–3 eggs, white or with faint bluish tinge, or (in Myanmar) spotted all over, mainly at larger end, with reddish. Brood parasitism by Asian Drongo-cuckoo (*Surniculus lugubris*) reported. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally common in mainland range. Common in Khao Pra-Bang Kham Wildlife Sanctuary, in Thailand, and Taman Negara National Park, in Peninsular Malaysia. Common in high forest in Sumatra; common in lowland forests throughout Borneo, including Sabah. In Sumatra, present in Gunung Leuser, Bukit Tigapuluh and Way Kambas National Parks, being common in the last; recorded from the now destroyed Padang-Sugihan Wildlife Reserve, in S Sumatra. In Borneo, common in Danum Valley Conservation Area (Sabah), present in Similajau National Park (Sarawak), and common to very common in Tanjung Puting National Park (S Kalimantan).

**Bibliography.** Buij *et al.* (2006), Chasen (1939), Chasen & Hoogerwerf (1941), Danielsen & Heegaard (1995), Delgnan (1963), Duckworth & Kersh (1988), Duckworth *et al.* (1997), Fogden (1970), Gore (1968), Hopwood (1919), Hume & Davison (1878), Hume & Oates (1889), bin Jalan & Galdikas (1987), Johns (1989), Lambert (1992), Lekagul & Round (1991), Madoc (1956), van Marle & Voous (1988), Medway & Wells (1976), Mees (1986), Nash, S.V. & Nash (1985a, 1988), Oberholser (1932), O'Brien & Kinnaird (1996), Parrott & Anderson (1996), Robson (2000), Sheldon *et al.* (2001), Smythies (1986), Smythies & Davison (1999), Thompson (1966), Wilkinson, Dutton & Sheldon (1991), Wilkinson, Dutton, Sheldon, Darjono & Noor (1991).

## 61. Chestnut-rumped Babbler

### *Stachyris maculata*

**French:** Timalie maculée **German:** Rostbüzel-Buschtimalie **Spanish:** Timali Maculado  
**Other common names:** Red-rumped Babbler

**Taxonomy.** *Timalia maculata* Temminck, 1836, Borneo.

Has sometimes been placed in genus *Macronus*. Three subspecies recognized.

#### **Subspecies and Distribution.**

- S. m. maculata* (Temminck, 1836) – S Thailand, Peninsular Malaysia, Riau Archipelago, Sumatra (including Bangka) and Borneo.
- S. m. banjakensis* Richmond, 1902 – Banyak Is, off NW Sumatra.
- S. m. hypopyrrha* Oberholser, 1912 – Batu Is, off W Sumatra.

**Descriptive notes.** 17–18.5 cm; 23–36 g. Relatively large, rather long-billed *Stachyris* babbler, dull olive-brown above with elongate chestnut rump plumes, dense black markings below. Nominative race has forehead to mid-crown olive-grey with vague blackish and narrow silvery streaking, shading to plain olive-brown on hindcrown to back and upperwing, dusky-chestnut lower back, rump and uppertail-coverts (all with elongate filoplumes); tail slightly browner than wings and with some chestnut fringes; lores to above eye blackish, submoustachial area, cheek and ear-coverts slightly shiny greyish-olive; chin and

throat blackish, breaking into broad blackish spotting on buffy-whitish breast to belly, flanks and vent dull grey-brown with ochre tinge, iris cream to orange-yellow (with darker outer rim, blue or purple orbital skin and retinal area; upper mandible black, lower mandible pale blue-grey to horn; legs grey or greenish-state to plumbeous, when singing, pale blue or turquoise-blue to pale green or bluish-green patches on neck side usually exposed. Sexes similar. Juvenile has brighter upperparts than adult, pale grey chin to breast, few black feathers on throat and foreneck, whitish central belly

**Breeding.** Mar–Sept in SE Asia, Mar–Apr in Sumatra, and Feb and May–Sept in Borneo. Nest a loose globe or cup, made of dry leaves, held together with a few bits of grass and roots, lined with thin layer of coarse grass-like material, placed 0.5–1 m above ground in centre of small palm or in tangle of creepers and dead leaves. Clutch 3 eggs, white or dull white; no information on incubation period; nestling period at least 10–11 days.

**Bibliography.** Anon. **Other common names:** Salvadori's Scimitar-babbler

**Taxonomy.** *Pomatorhinus erythrogenys* Vigors, 1832, "the district Simla-Almora", Himalayas, north India.

Forms *s* species group, and has commonly been treated as conspecific, with *P. maclellandi*, *P. gravivox*, *P. swinhoi* and *P. erythrocnemis*, all having similar plumage. Proposed race *haringtoni* (Himalayas from Sikkim E to Bhutan) merged with *ferrugilatus*. Four subspecies currently recognized.

### Subspecies and Distribution.

*P. e. erythrogenys* Vigors, 1832 – NE Pakistan (Murree Hills) E to N India (Uttaranchal Pradesh).

*P. e. ferrugilatus* Hodgson, 1836 – Nepal E to Bhutan.

*P. eimberhis* Salvadori, 1889 – E Myanmar.

*P. e. celatus* Deignan, 1941 - NW Thailand.

yellow; bill greyish or pale horn-brown, ivory-white base of lower mandible; legs flesh-brown to pale horn. Sexes similar. Juvenile has all rusty parts paler, and upperparts, edges of wings and wing-coverts have rusty wash. Race *ferrugilatus* is smaller than nominate, darker olive above, chin to upper breast dusky grey with whitish feather edges; *imberbis* is smaller than previous, like nominate in coloration but lores greyish, malar line weaker, breast with no "ghost" streaking, juvenile has most of underparts bright rufous and fading on abdomen to whitish; *celatus* is very like last, but lores darker grey, malar line absent, orange-rufous marginally paler, iris red. Voice. Song consists of short clear piping irregular phrases, very like that of *P. maclellandi* and most phrases more rushed, broken up and liquid-sounding, and presumed female notes much shorter, more staccato. Typical duets include "whi-u-ju-whi-u-...", "iu-chu-ip-iu-chu-...", and "yu-u-yi-yu-u-..."; also as a very quick, rich stuttering 3-note duetted "kvird'kup!", tumbling in pitch, and as similar but 1 noted "kvikuu", with first note much higher and shriller than final one (very like a song of *P. maclellandi*); also staccato, mellow "breer, b'dakwip!". Also a high clear ascending "pu" or "ju" followed by 3 or 4 higher well-spaced grating rattles, "jrr-jrr-jrr-jrr". When alarmed, gives rattling "whih-whihhhhh" and harsh "whit-it" or "whoi-whittittittit", the "whoi" note (recalling sound made by stone dropped in water) sometimes given singly.

**Habitat.** Thick scrub and dense undergrowth at forest edge, scrub in open pine forest, secondary growth, bramble thickets, dense overgrown nullahs, bush-covered and scrub-covered hillsides, bushes bordering fields, abandoned cultivation; in Bhutan reported particularly from scrub around villages. Found at 305–2400 m, occasionally to 3000 m, in Indian Subcontinent; 915–2000 m in SE Asia.

**Food and Feeding.** Insects, larvae, chrysalids, seeds and berries. Mostly in pairs in summer and in small parties of up to twelve individuals in winter (but such parties unreported in Bhutan); only occasionally joins bird waves. Spends most of time on ground among leaf litter, occasionally ascending trees in hoops.

**Breeding.** Feb-Jul: in tutan, calling individuals and duetting pairs occupy territories Mar–Sept. Nest, built by both sexes, a loose dome with broad entrance high up at side, or sometimes open at both ends, made of coarse grasses, dry fern, bamboo or other leaves, leaf stalks, plant fibres, moss roots etc., sparsely lined with fine grasses, fibres and rootlets, placed on ground, in depression, sheltered by brushwood, tree roots, ferns, grass, bush or rock, or sometimes 0.6–1.2 m above ground in thick bush. Clutch 2–4 eggs (usually 3 in India), white; incubated by both sexes; nestlings fed by both sexes; no information on duration of incubation and nestling periods.

**Status and Conservation.** Not assessed. Frequent but very local in Pakistan. Common and widespread in Nepal. Common and widespread throughout temperate zone and foothills of Bhutan; near Zhemgang, density of 2 territories/km of road at 1600–1900 m. Common in India, where seen intermittently in Rajaji National Park (Uttar Pradesh), common in Corbett National Park (Uttaranchal Pradesh), uncommon in Mahajatal Harsang Wildlife Sanctuary (Himachal Pradesh), fairly common in well-wooded areas of the New Forest campus at Dehra Dun, and in Dehra Dun valley (Uttaranchal), and present in Buxa Tiger Reserve (West Bengal). Common in Doi Inthanon National Park, in Thailand.

**Bibliography.** Ali & Ripley (1971), Ali *et al.* (1996), Allen *et al.* (1997), Bingham (1903), Collar (2006), Cook (1913), Deignan (1963), Gaston *et al.* (1994), Grimmer *et al.* (1998), Hume & Davison (1878), Hume & Oates (1889), Inskip & Inskip (1991), Inskip *et al.* (2000), Lekagui & Round (1991), Ludlow & Kinnear (1944), Martens & Eck (1995), Mishra (1997), Mohan (1997), Oates (1883, 1894), Pandey *et al.* (1994), Rasmussen & Anderton (2005), Rippon (1897), Robson (2000), Singh (2000), Smith *et al.* (1940, 1943), Smythies (1986), Snienberg (2005), Steinbacher (1967, 1969), Stevens (1923), Tvmstra (1993), Vaurie (1954b), Wickham (1929).

### 65. Spot-breasted Scimitar-babbler

*Pomatorhinus maclellandi*

**French:** Pomatorhin de McClelland **German:** Fleckenbrustsbler **Spanish:** Cimitarra Moteada  
**Other common names:** McClelland's Scimitar-babbler

**Taxonomy.** *P[omatorhinus]. McClellandi* Godwin-Austen, 1870, "at Nenglo beyond Asálu, under the Burraile range", Assam, India.

Forms a species group, and has commonly been treated as conspecific, with *P. erythrogeus*, *P. gravivox*, *P. swinhoei* and *P. erythrocnemis*, all having similar plumage. Monotypic.

**Descriptive notes.** 22 g, cm, 47.61 g. Smallish, semiarboreal, olive brown above and white below, with rufous ear-coverts and vent, and random ashy-olive blotchy spots on breast. Forehead is rufous-olive, shading to rufescent olive-brown on crown, upperparts, upperwing and tail; lores pale brownish. Ear-coverts dull rusty rufous, shading distally more olive, submoustachial line whitish with some pale olive flecking, malar long, narrow and black; chin to mid-belly white with irregular pale-olive blotch-like spots across breast and upper belly, flanks ochraceous-olive, thighs

mellow, often with higher, slightly falling "péék" note or, less often, harsher, burry downsurred "bréér" by second bird; also quick staccato "kerwick!", second note upturned, or similar "kerwérk!", second note only slightly higher. When alarmed, utters harsh rattle preceded by quick high notes, "wi-wi-chiitit"; also a rapid mechanical rattle preceded by loud frog-like sound, "whoip-tutututututut"

**Habitat.** Scrub-jungle and forest undergrowth, thickets in forest clearings, and abandoned cultivation, at 750–1830 m.

**Food and Feeding.** Insufficient information. Presumably as for *P. erythrogenys* and *P. gravivox*.  
**Breeding.** Mar-Jun. Nest a loose dome with side entrance, made of coarse grasses, dry fern, leaves, plant fibres, moss roots etc., sparsely lined with fine material, placed on ground or low in bush; like that of *P. erythrogenys*. Clutch 3-4 eggs, white. No other information.

**Movements.** Resident; reports of wandering to very low elevations in winter require substantiation.

**Status and Conservation.** Not assessed. Rare in E Bhutan. Current status in India uncertain; few recent records, but present in Ngangpui Wildlife Sanctuary (Mizoram). Presumably a rare resident in Bangladesh, where only one recent record. Common in W Myanmar, including in Natmataung National Park.

**Bibliography.** Ali & Ripley (1948, 1971), Birand & Pawar (2004), Collar (2006), Godwin-Austen (1870), Grime *et al.* (1998), Hopwood & Mackenzie (1917), Oates (1883), Rasmussen & Anderton (2005), Ripley (1952), Robson (2000), Singh (1995), Smythes (1949, 1986), Spierenburg (2005), Stanford & Mayr (1941), Stanford & Ticehurst (1938), Stevens (1914), Stresemann & Heinrich (1940a), Stuart Baker (1893), Thompson *et al.* (1993), Venning (1912), Wickham (1929).

## 66. Black-streaked Scimitar-babbler

*Pomatorhinus gravivox*

**French:** Pomatorhin chanteur    **German:** Schwarzstrichelsäbler    **Spanish:** Cimitarra Rayada

**Taxonomy.** *Pomatorhinus gravivox* David, 1873, southern Shaanxi, China.

Forms a species group, and has commonly been treated as conspecific, with *P. erythrogenys*, *P. maclellandi*, *P. swinhoi* and *P. erythrocnemis*, all having similar plumage. In China, proposed race *sowerbyi* (known only from type locality, 12 miles [c. 19 km] S of "Fushih", in N Shaanxi) treated as synonym of nominate and *stoneae* (from extreme NW Yunnan) merged with *dedekensi*. Five subspecies recognized.

### Subspecies and Distribution.

*P. g. gravivox* David, 1873 – NC China (S Gansu E to S Shanxi, S to N & NE Sichuan, W Henan and NW Hubei).

*P. g. cowensae* Deignan, 1952 – SC China (C & SE Sichuan, SW Hubei).

*P. g. dedekensi* Oustalet, 1892 – S China (SE Xizang, W Sichuan, extreme NW Yunnan).

*P. g. decarlei* Deignan, 1952 – S China (NW Yunnan and immediately adjacent parts of SW Sichuan and extreme SE Xizang).

*P. g. odicus* Bangs & Phillips, 1914 – NE & extreme E Myanmar, S China (Yunnan except NW, and SW Guizhou), N Laos and N Vietnam (Tonkin).

**Descriptive notes.** 21–25 cm; 46–79 g. Smallish to medium-sized scimitar-babbler, olive-brown above and white below, with rufous-tan ear-coverts, flanks and vent, and bold black streaking on breast. Nominate race has forehead and supercilium rusty rufous, crown and upperparts, including upwearing and tail, grey-washed olive-brown; lores greyish-white, ear-coverts dull rusty tan, submoustachial stripe whitish with blackish flecking, malar line blackish, very broad and relatively short, neck side to flanks buffy tan with greyish fringes; chin to belly white, breast with neatly aligned long blackish streaks, vent rufous-tan; iris

chestnut-red to brownish-grey, pale yellow or creamy white; bill grey, lower mandible sometimes yellowish or greenish basally; legs vary from leaden or flesh-brown to yellowish-green and reddish-yellow. Sexes similar. Juvenile is washed rufous-tan below, with very faint or no spotting on breast. Race *odius* is less grey, more olive, above than nominate, no rufous supercilium, mostly rufous submoustachial, richer rufous ear-coverts, richer and more extensive rufous on breast above and flanks, shorter and slightly sparser breast streaks; *decarlei* is very like previous, but slightly more olive-tinged above, rufous areas slightly duller; *dekekeni* is like last but a shade colder and greyer above, with slightly weaker, greyer breast streaks, *covensae* is like nominate but browner above, forehead more chestnut, ear-coverts more rufous, breast streaks blacker and more extensive, flanks dark cinnamon with olive suffusion. Voice. Evidently very similar to that of others in species complex, but no evidence yet of dust. In China, "whi-whup" or "whi-wru" from single bird in SE Xizang, and husky quick "whi-wip" recorded in N Sichuan; rapid-fire "whi'chu" or "whi'tu" from single bird in N Vietnam. Alarm calls "whoi-t't't't't", "whoiptut'ut'ut'ut'ut'ut" or "whup-which'ch'ch'ch'ch'".

**Habitat.** Open forest, forest edge, scrub-jungle, secondary growth in clearings, thickets, dry scrub (alang grass, abandoned cultivation, bamboo; at 1220–2600 m in SE Asia, but 200–3700 m in China and 3260–3800 m in summer in Xizang).

**Food and Feeding.** Insects and vegetable matter; raids cultivation for left-over rice, millet and taro. Found singly or in pairs. Forages on or near ground, rummaging among leaf litter.

**Breeding** Mar-Jun in China; multi-brooded. Nest an untidy dome with side entrance, made of grasses, bits of fern fronds, leaf skeletons, dry bamboo and other leaves, thin twigs and stalks, lined

low, black base of upper mandible; legs bluish-slate or greenish-slate to brownish. Sexes similar. Juvenile is duller and paler than adult, slightly browner above (but reported also as reddish-olive above), rufous on forehead, and rusty on breast and flanks. Race *leucogaster* is smaller than nominate, more olive-grey above, with slightly paler and less extensive chestnut on neck and body sides; *salimali* has blacker crown and ear-coverts; *cryptanthus* is very slightly more rufous-tinted above, slightly less grey on hindcrown, often more rufous on nape; *meursi* is somewhat slatter on upperparts, with blacker tail; *nuchalis* is slightly smaller and shorter-billed, crown concolorous with upperparts, variably broad or intense rufous extending around nape, and breast side and flanks mostly ochrous-grey with weak rufous-chestnut edges; *ripponi* is very like previous, but almost no trace of rufous on breast side and flanks; *difficilis* is like last two, but upperparts warmer, wings and uppertail dark ochraceous rufescent-brown; *olivaceus* resembles *nuchalis*, but crown and upperparts more olive-toned; *humilis* is similar to last but small (19–20 cm), and shorter-billed; *annamensis* is also similar but has darker crown demarcated from mantle, maroon-chestnut of nape and neck continuing down flanks; *klossi* has crown olive, upperparts somewhat more rufous-tinted. Voice. As with congeners, many songs are duets that sound as if by single bird. Song a series of usually 3–7 clear, quite fast hollow piping notes, e.g. "hu-hu-hu-hu-hu", "wu-hu-hu-hu-hu", "wu-hu-wu-wu-pu", "wu-hu-wu-wu-wu-wu-wu-wu-wu-wu-wu" or "whu-whu", sometimes with more abrupt, higher and more stressed first note or longer pause between first and second notes. May give faster "whuhuhuhuhuhu" or shorter "wu-hup" or "oo-hu" (perhaps by female), which may be combined in duets as "wu-hu-hu-wu-hu-wu-hup-wu-hu-hu-hu...". Calls include hoarse raspy syncopated gurgling, "weesh-wu-weeshweesh!", or 2-note version, second note higher, but same intoned rattle "Kurda-weesh-sh' sh-sh", when alarmed, harsh mocking "whihhihihi" and "whieniti", etc.; excited pairs give variety of mixed calls, including rather nasal, husky "whor-whor-whor", very nasal

"waaah" or "woieee", jumbled chattering mixed with quite high "who" notes, short clear "oh" and "whu" notes, and throaty "wuhu-wuhu" and "wuhu wuhu-wip".

**Habitat.** Dense undergrowth in deciduous and evergreen broadleaf forest, secondary growth, well-wooded ravines, mixed bamboo forest, scrub-jungle, and grassland; to 2650 m in India, 245–1500 m in Nepal, 400–1590 m in Bhutan, up to 2600 m in SE Asia.

**Food and Feeding.** Insects, also small seeds and berries. Found in pairs during breeding season; otherwise in small parties, joining mixed feeding flocks which often contain other scimitar-babblers and, in Bhutan, *Garrulax monileger* and *Garrulax pectoralis*. Forages on ground, hops in undergrowth and ascends trees.

**Breeding.** Nov.–Aug. Nest, built by both sexes over c. 10 days, a large, loose dome, usually on its side, entrance at smaller end or at side, made of dry bamboo or other leaves, coarse grasses, rootlets, twigs, strips of bark and bracken leaves, lined (often thickly) with thin strips of dry bark, bark fibres, fine grasses, shredded dry bamboo leaves and rootlets, placed low down in bamboo clump or thick bush, grass clump, bank at foot of tree, or buried among dry leaves on ground, in depression on ground or at foot of small screw pine (*Pandanus*), up to 1 m above ground. Clutch 2–5 eggs (usually 3–4 in India and Myanmar), white; incubation by both sexes. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Frequent in Nepal up to 915 m, then rare to 1500 m. Local but frequently recorded in Bhutan. In India, fairly common in W Himalayas up to 1500 m, becoming locally common in E up to 2000 m; fairly common in Kalesar Wildlife Sanctuary (Haryana), rare on New Forest campus at Dehra Dun and uncommon in Dehra Dun valley (Uttaranchal); common in Nameri National Park and uncommon in Kaziranga National Park (Assam), and present elsewhere in NE India in (at least) Buxa Tiger Reserve (West Bengal), Eaglenest Wildlife Sanctuary and Mouling National Park (Arunachal Pradesh) and Balphakram National Park (Meghalaya). Generally fairly common to common in SE Asian range. Common in Khao Yai and Kaeng Krachan National Parks, in Thailand. Common (at least before 1970) at Bokor and in Cardomom Mts. in Cambodia. Occasional in Xe Pian National Biodiversity Conservation Area (NBCA), Phou Xang He NBCA, Dong Hua Sao NBCA and Phou Dendin NBCA, in Laos, and present in Phou Khaokhoay, Nakai-Nam Theun and Hin Namno NBCAs. In Vietnam, present in Thuong Da Nhim and Chu Yang Sin Nature Reserves (Da Lat Plateau, in S Annam), and in five protected areas in the Annamese lowlands, although scarce in Nam Bai Cat Tien National Park (Cochinchina).

**Bibliography.** Ali & Ripley (1948, 1971), Allen *et al.* (1997), Barua & Sharma (1999, 2005), Bingham (1903), Birand & Pawar (2004), Chasen (1939), Choudhury (2003), Collar (2006), Cook (1913), David-Beaulieu (1932, 1939, 1944, 1950), Davidson *et al.* (1997), Deignan (1942, 1963), Delacour & Jabouille (1931a), Dickinson (1970), Duckworth *et al.* (1998), Eames (1995), Eames, Eve & Tordoff (2001), Eames, Steinheimer & Ros Bansok (2002), Engelbach (1932), Evans & Timmins (1998), Garthwaite & Ticehurst (1937), Godwin-Austen (1870), Grimmett *et al.* (1998), Hopwood (1912, 1919), Hopwood & Mackenzie (1917), Hume (1877, 1880), Hume & Davison (1878), Hume & Oates (1889), Inskipp & Inskipp (1991), Kalsi (1998), Katti *et al.* (1992), King *et al.* (2001), Lê Xuân Canh *et al.* (1997), Lekagul & Round (1991), Ludlow & Kinnear (1944), Mayr (1938), Medway & Wells (1976), Mohan (1997), Neath (2001), Oates (1883), Rasmussen & Anderton (2005), Robinson & Kloss (1919a), Robson (2000), Robson, Eames, Nguyễn Cu & Truong Van La (1993a, 1993b), Robson, Eames, Wolstencroft *et al.* (1989), Round (1998), Showler, Davidson, Chanthavi Vongkhamheng & Khounmee Salivong (1998), Singh, A.P. ## 70. Indian Scimitar-babbler

### *Pomatorhinus horsfieldii*

**French:** Pomatorhin de Horsfield **German:** Horsfieldsäbler **Spanish:** Cimitarra India  
**Other common names:** Deccan/peninsular Scimitar-babbler

**Taxonomy.** *Pomatorhinus horsfieldii* Sykes, 1832, the Deccan [= Mahabaleshwar, Satara North], India. Has been treated as conspecific with *P. schisticeps* and *P. melanurus*; vocalizations extremely like those of former (from which differs only in lack of rufous on plumage), and perhaps better treated as conspecific; further field study needed. Four subspecies recognized.

**Subspecies and Distribution.**

*P. h. obscurus* Hume, 1872 – W India (SW Rajasthan S to S Gujarat and SW Madhya Pradesh).

*P. h. horsfieldii* Sykes, 1832 – SE Gujarat S to Goa and NW Karnataka, and E to C Madhya Pradesh, Orissa and NE Andhra Pradesh.

*P. h. travancorensis* Harington, 1914 – Goa S to Kerala and W Tamil Nadu.

*P. h. maderaspatensis* Whistler, 1936 – C & S Andhra Pradesh and N Tamil Nadu.

similar. Juvenile lacks black lateral crownstreaks, has upperparts more golden olive-brown, white feathers of lower throat with faint black tips, lower underparts washed and mottled with rufous. Race *obscurus* is paler, more smoky grey, than nominate, with neck and breast sides concolorous with upperparts; *maderaspatensis* is like previous, but more olive-toned on upperparts and flanks; *travancorensis* is richer olive-brown above. Voice. Flock-members and pair-members keep in touch by yellow bubbling or gurgling calls and song duets, the combined sound seeming to be given by one bird. Songs include variety of low, mellow, hollow-sounding series of hoots or "bouncing-bari" series starting with a note, presumed female joining (if at all) mid-way or at end, usually with higher-pitched "gu-tork!", commonest songs consist of 3–5 slow mellow hoots, often with either bird's "gu-tork!" presumed, alternating males may alternately give same song type, becoming more guttural when agitated, hoots may be all on same pitch and at even tempo, or first may be higher (or lower) and offset. Male *travancorensis* gives musical, flute-like "woi-no-ho-ho", "oo-pu-pu" or "oo-pu-pu-pu", this immediately followed by female's subdued "kraku" or "krakam". Also described as a mellow, lute "oo-pu-pu-pu-pu". Bouncing-bari song much as that of *schisticeps*, but slower and usually slightly decelerating; intermediate songs similar but shorter

and faster, or longer and notes more hooting. Calls include a variety of chirps and rattles uttered while feeding or when suspicious; quick hoarse hoots running into short, higher-pitched, ascending guttural rattles; "pop pop-prrr"; a deep guttural "woch-wohoro"; and a sharp "kir-r-r-r" in alarm.

**Habitat.** Deciduous, moist deciduous, semi-evergreen and evergreen forest, cardamom sholas, bamboo and *Strobilanthus* patches, thorn and lantana scrub, and dense bush-jungle; at 915–2135, locally to 2400 m.

**Food and Feeding.** Insects, grubs, spiders (Araneae); also berries and flower nectar. Found in pairs during breeding season, otherwise in small parties of 4–10 individuals; often in association with mixed feeding parties. Forages on ground under dense undergrowth, flicking aside or turning over leaves or digging vigorously in mulch. Also hops along moss-covered branches or up trunks of trees.

**Breeding.** Oct–Jun throughout range. Nest, built by both sexes, described as a loose, often large, dome, with entrance on upper side, or a semi-domed cup, made of dead or decaying leaves, dry grasses, moss and moss roots, plant stems, grass roots, rootlets and fibrous bark strips, lined with fine grasses, moss roots, rootlets and dead leaves, placed on ground among dead leaves or moss, in or at base of bush or shrub, in clump of ferns or grass, in recess in trailside bank, on rock ledge or in crevice or hollow in tree trunk, usually 0.3–0.6 m above ground, exceptionally to 1.8 m. Clutch 2–5 eggs (usually 4–5), white; no information on duration of incubation and nestling periods; nestlings fed by both sexes.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Locally common in peninsular hills; fairly common in Bandhavgarh National Park, in Madhya Pradesh, and present in Mudumalai National Park, in Tamil Nadu.

**Bibliography.** Ali (1942, 1955), Ali & Abdullali (1936), Ali & Ripley (1971), Collar (2006), Gokula & Vijayan (1997), Grimmett *et al.* (1998), Hume & Oates (1889), Kotagama & Goodale (2004), Rasmussen & Anderton (2005), Whistler & Kinnear (1932), Zacharias & Gaston (1993).

## 71. Sri Lankan Scimitar-babbler

### *Pomatorhinus melanurus*

**French:** Pomatorhin de Ceylan **German:** Schwarzschanzäbler **Spanish:** Cimitarra Cingalesa

**Taxonomy.** *Pomatorhinus melanurus* Blyth, 1847, Urugaha, south of Kalutara, Western Province, Sri Lanka.

Has been treated as conspecific with *P. horsfieldii* and sometimes also *P. schisticeps*. Two subspecies recognized.

**Subspecies and Distribution.**

*P. m. melanurus* Blyth, 1847 – W part of SC Sri Lanka (wet lowlands and W hills).

*P. m. holdsworthi* Whistler, 1942 – E part of SC Sri Lanka (dry lowlands and E hills).

**Descriptive notes.** 19–21 cm. Nominative race has forehead blackish, shading to dark greyish-brown on crown and to dark rufescent brown on upperparts, with dull greyish-brown upperwing and tail; bold white supercilium from bill base above blackish lores to upper neck side; cheek and ear-coverts blackish, shading to rufescent brown neck side; chin and submoustachial area to belly white, flanks and thighs dark rufescent brown, lower belly dull greyish or greyish-white; iris brownish-red or dull red; bill yellow, darker around nares; legs greyish-blue to yellowish-brown. Differs from similar *P. horsfieldii* in smaller size, yellower

and shorter bill, proportionately much shorter tail, weaker (black) lateral crownstreaks, much richer rufescent brown upperparts, richer rufescent flanks. Sexes similar. Juvenile has greyer head, less white on underparts, more rufous on upperparts, breast side and flanks, and straighter bill. Race *holdsworthi* is less rufescent, more yellowish, above and on flanks than nominate. Voice. Vocalizations differ distinctly from those of *P. horsfieldii*, being higher-pitched, with more melodious and less hollow-sounding notes; an "oop-ooop-ooop-ooop..." and sonorous, pleasant "pawp-pawp" answered presumably by female with "kaa-kree, kaa-kree"; also descending "do do do do", "pop pop-prrr" and deep "woch wohoro". Call of male with family party "twoi twoi twoi"; dependent young give plaintive mewling when solicited food.

**Habitat.** Shady forests and woods, particularly near streams, also bamboo stands, low jungle and thick cover; sea-level to 2100 m.

**Food and Feeding.** Presumed to feed on invertebrates. Forages on ground, low branches and vertical trunks and on large limbs of trees, working its way upwards in fashion of a woodpecker (Picidae).

**Breeding.** Dec–Feb. Nest untidy, usually made of moss, grass roots, fibres and dead leaves, placed in tree crevice between projecting piece of bark and trunk, sometimes on rock ledge. Clutch 3–5 eggs, pure white. No other information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Common and widely distributed in lowlands and hills, but more abundant in latter. Common in Sinharaja Forest Reserve; uncommon to common in Horton Plains National Park.

**Bibliography.** Collar (2006), Grimmett *et al.* (1998), Harrison (1999), Henry (1998), Kotagama & Fernando (1994), Legge (1880), Phillips (1978), Rasmussen & Anderton (2005), Ripley (1946), Wait (1925), Whistler (1944).

## 72. Chestnut-backed Scimitar-babbler

### *Pomatorhinus montanus*

**French:** Pomatorhin à dos marron **German:** Rotrückensäbler **Spanish:** Cimitarra Dorsicastaña  
**Other common names:** Yellow-billed Scimitar-babbler

**Taxonomy.** *Pomatorhinus montanus* Horsfield, 1821, Mount Merbabu and Mount Prah, central Java. May be close to *P. schisticeps*. Races *occidentalis* and *bornensis* smaller and brighter than Javan ones, and study of differences, including vocal ones, required; situation further complicated, however, by evidence that in Java and Sumatra, at least, upland birds are precocious, flocking and noisy, whereas lowland populations in Sumatra, Borneo and Peninsular Malaysia are skulking, unsociable and thought possibly to produce only the triple hooting call. Further research needed. Four subspecies recognized.

**Subspecies and Distribution.**

*P. m. occidentalis* Robinson & Kloss, 1923 – extreme S Thailand, Peninsular Malaysia and Sumatra.  
*P. m. bornensis* Cabanis, 1851 – Bangka I and Borneo.  
*P. m. montanus* Horsfield, 1821 – W & C Java.  
*P. m. otolanderi* Robinson, 1918 – E Java and Bali.

**Descriptive notes.** 19–21 cm. Small scimitar-babbler with relatively short decurved bill, grey-crowned and black-faced with white supercilium, rich chestnut upperparts and flanks, white underparts. Nominate race has crown slaty grey, switching on nape to rich rufous-chestnut upperparts, neck side and flanks, upperwing fringed slightly browner, tail chestnut-tinged dark brown; weak white supercilium from above nares; lores, cheek and ear-coverts blackish or blackish-grey, chin and submoustachial area to mid-belly white, thighs dark grey, vent dull ochrous-chestnut; iris dull or pale yellow to pale brown; bill yellow to

horn, basal half of upper mandible black; legs greenish-slate to pale slaty blue. Sexes similar. Juvenile is duller than adult, rufous parts of plumage paler and rufous less extensive on flanks, ear-coverts mostly chestnut, forehead with rufous fringe, crown washed rufous. Race *otolanderi* is like nominate but supercilium only postocular; *occidentalis* has slightly more olive-grey crown, always full-length (i.e. preocular as well as postocular) and bolder white supercilium, bright rufous-chestnut back and flanks, greyer-edged flight-feathers, shorter tail; *bornensis* is like last, but wings and tail blacker. **VOICE.** Songs in N Borneo (Sabah) and Bali similar, a quickish “wu-pwi” given 3–5 times in series, with immediate response from second bird “wu-pu’ pu’ pu’ pu’ pu’ pu’”, also a throaty, husky “whor-wup”; in Java a very quick, quite grating “hu’wi” or “wihu’wi” repeated in series, while second bird gives repeated, monotonous, lower-pitched “wupup-wupup-wupup-wupup”. In Java, alarm a rather harsh “whit’it’it’it’it’it’” or “whip’ip’ip’ip’ip’ip’ip’”.

**Habitat.** Undergrowth and grass in primary lowland, submontane and lower montane broadleaf evergreen forest, secondary and disturbed forest, lightly logged forest, pure bamboo stands, overgrown clearings, occasionally in *Albizia* plantations; to 1370 m in Peninsular Malaysia, to 1200 m in Sumatra, 1400–2000 m in Java, and 500–2800 m in Borneo.

**Food and Feeding.** Beetles (Coleoptera), crickets and grasshoppers (Orthoptera), cicadas (Cicadidae), earwigs (Dermaptera), caterpillars, grubs, also spiders (Araneae); also ginger seeds, flower pods, fruit and berries. Found singly, in pairs, or in small parties, often associating with other species in bird waves, particularly *Garrulax rufifrons* in Java. Usually forages in undergrowth and lower middle storey, sometimes ascending to middle storey and even canopy; gleans items from foliage and bark, concentrating on epiphyte-covered trunks and large boughs.

**Breeding.** Apr–Jun and Nov–Dec in Malay Peninsula, in all months except Mar and Oct (but mainly May–Jun) in Java, and Oct–Feb in Borneo; possibly multi-brooded. Nest a large dome or sheltered cup, made of coarse grasses, loosely linked pieces of padi, fern fronds, stems decorated with moss, large grass leaves or old leaves and grasses, lined with finer leaves or grass stems, placed in grassy undergrowth or scrub and grass at edge of grassland or on bank face. Clutch 2–5 eggs (2–3 in Borneo), white, but those in one Borneo nest described as irregularly marked with reddish-brown. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common in Peninsular Malaysia. In Borneo, uncommon in Sabah; present in Similajau National Park (Sarawak) and Gunung Niut Nature Reserve (W Kalimantan). In Sumatra, common in primary and disturbed habitats, and present in Gunung Leuser, Bukit Tigapuluh and Way Kambas National Parks, being scarce in last. Common in Gunung Gede-Pangrango National Park, in W Java.

**Bibliography.** Andrew (1985), Buij *et al.* (2006), Chasen (1939), Chasen & Hoogerwerf (1941), Danielsen & Heegaard (1995), Davison (1997a), Duckworth & Kelsch (1988), Duckworth *et al.* (1997), Holmes (1996), Holmes & Burton (1987), Johns (1989), MacKinnon (1988), Madoc (1956), van Marle & Voous (1988), Medway & Wells (1976), Mees (1986), O’Brien & Kinnaird (1996), Parrott & Andrew (1996), Priem & Heegaard (1988), Rinke & Jensen (2000), Robinson (1928), Robinson & Kloss (1923), Robson (2000), Sharpe (1889), Sheldon *et al.* (2001), Smythies & Davison (1999), Sody (1956), Thompson (1966), Voous (1948), Wilkinson, Dutson & Sheldon (1991), Wilkinson, Dutson, Sheldon, Darjono & Noor (1991).

## 73. Streak-breasted Scimitar-babbler

### *Pomatorhinus ruficollis*

**French:** Pomatorhin à col roux **German:** Rothalsäbler **Spanish:** Cimitarra Cuellirrufo  
**Other common names:** Rufous-necked Scimitar-babbler; Nepal Rufous-necked Scimitar-babbler (Himalayas)

**Taxonomy.** [*Pomatorhinus*] *Ruficollis* Hodgson, 1836, Nepal.

Closely related to *P. musicus* and formerly treated as conspecific. In C Laos (Nam Theun watershed), population of scimitar-babblers exhibits signs of intergradation between present species (race *beaulieu*) and *P. schisticeps*, such that attribution to one species or the other has proved problematic, hence triggering opinion that the two species may be conspecific; in Himalayas and upper Myanmar, however, the two occur alongside one another and behave as separate species; more work needed. Birds in SC China (SE Sichuan S to N Guangxi and W Hunan) formerly treated as race *intermedius*, but latter name invalid, as preoccupied; replaced by new name *hunanensis*. Nominate race intergrades with *godwini* in E Nepal. Contrary to some recent opinions, *styan* appears to be a valid race, although considerable intermediacy among races suggests much clinal variation. Other named races are *bhamoensis* (from Bhamo area, in NE Myanmar), synonymized with *similis*, and *usheri* (C Sichuan, in SC China), synonymized with *eidos*. Thirteen subspecies currently recognized.

**Subspecies and Distribution.**

*P. r. ruficollis* Hodgson, 1836 – N India (E Uttaranchal Pradesh) E to EC Nepal.  
*P. r. godwini* Kinnear, 1944 – EC Nepal E to NF India (Arunachal Pradesh) and adjacent S China (SE Xizang).  
*P. r. bakeri* Harington, 1914 – NE Indian hill states (S of R Brahmaputra), SI, Bangladesh and W Myanmar.  
*P. r. similis* Rothschild, 1926 – N Myanmar and S China (NW & W Yunnan E to SW Sichuan).  
*P. r. spodiops* Seeborn, 1884 – F China (S Gansu and N & NE Sichuan) to S Hunan and N Zhejiang.  
*P. r. eido* Yang, 1930 – SC China (C Sichuan and adjacent extreme N Yunnan).  
*P. r. laurenti* La Touche, 1921 – Künming area of C Yunnan (SC China).  
*P. r. alpinus* La Touche, 1923 – SC China (SW Yunnan) and extreme S Laos.

*P. r. beaulieu* Delacour & Greenway, 1940 – N & C Laos.

*P. r. reconditus* Bangs & Phillips, 1914 – S China (SE Yunnan, SW Guangxi) and N Vietnam (Tonkin, N Annam).

*P. r. hunanensis* Cheng Tsohsin, 1974 – SE China (SE Sichuan and Guizhou E to W Hunan and N Guangxi).

*P. r. stridulus* Swinhoe, 1861 – SE China (F Hunan and Guangdong E to S Zhejiang and Fujian).

*P. r. nigrostellatus* Swinhoe, 1870 – Hainan I.

**Descriptive notes.** 16–19 cm; 19–39 g. Small scimitar-babbler, warm brown above with rufous-chestnut nape and neck side, pale supercilium, black mask and broad breast streaks; bill shorter and less decurved than that of congeners. Nominate race has crown dull ochrous-brown, clear-cutting to dull rufous-chestnut nape and upper mantle, shading to warm ochrous olive-brown on remaining upperparts, upwiping and tail; long broad supercilium white, lores, cheek and ear-coverts black but lower ear-coverts with some white streaks, neck side below end of supercilium and behind ear-coverts rufous-chestnut; chin,

submoustachial area and throat white, breast and mid-belly white with long broad dull ochrous-olive streaks, flanks, lower belly, thighs and vent dull grey-tinged ochrous-olive; iris pale red to crimson-brown or dark brown; upper mandible black with yellow tip, lower mandible yellow to yellowish-white; legs greenish-grey or yellowish-plumbeous to brown. Sexes similar. Juvenile is more rufous above than adult, with white throat and plain rufous-chestnut breast. Race *godwini* has darker crown and more rufescent upperparts than nominate, streaking below duller; *bakeri* has paler, weaker underpart streaking, slightly paler and colder upperparts, usually yellow eyes, mostly yellow bill; *similis* is very like nominate but ear-coverts browner, bill almost all yellow (only extreme base of upper mandible dark); *laurenti* is like previous, but has pinkish bill, more rufous-washed upperparts, purer greyish underparts, bill shorter; *alpinus* has greatly reduced breast streaking (leaving breast very white), flanks olive-brown, bill relatively long, only base of upper mandible blackish; *beaulieu* is very like last, but greyer on crown and flanks; *reconditus* is like nominate, but breast streaks pale rufous-chestnut, flanks more rufous, upperparts richer, and rufous-chestnut on nape and upper mantle broader and stronger; *eidos* is like nominate, but breast streaks slightly browner, rufous-chestnut of neck deeper, upperparts richer; *styan* is smaller than previous, and with greyer-tinged breast streaks; *stridulus* is like last in size but bill a little stouter, colour richer above, and with streaking and lower underparts rich rufous-chestnut (closely resembles smaller version of *reconditus*); *hunanensis* is small, with dark brown breast streaks, rufous neck patch; *nigrostellatus* has darker chestnut neck side with colour extending to flanks, breast streaks maroon-brown and dense but with frayed white fringes (creating scalier appearance when plumage fresh). **VOICE.** Song in SE Asia a loud, clear, rather high piping “u-hu-hu”, “wu-wu-wu”, “wu-wee-wu” and similar, uttered quite quickly; sometimes slower “wu-wu” or fuller-sounding “whu-whi” or “u-whi wi”; elsewhere described as quick, mellow whistle of 3 (occasionally 2 or even up to 10) short notes, “win-wun-wun”, first note higher or lower in pitch (like one song type of *P. schisticeps* but higher-pitched, first note higher or lower and more slurred, all notes more liquid). Contact call a loud, bright, raspy, strident uplurred “wreep”, given usually in ones, twos or threes, and often ending with harsh higher rolled gurgle, e.g. “wreep-wreepwreep’s’s’s’h”; when alarmed, harsh scolding rattles, e.g. “whi-whi-whi whi-whi-whi-whi-whi”, “chrrurururur”, “whi-wi chutututut”, “chutututut”, “whi-wi-irritirrit”.

**Habitat.** Dense scrub on hillsides, dense undergrowth in open forest, open bamboo-jungle, rhododendron shrubs, brambles, bracken, tea gardens and nearby jungle edge, thickets, hedges, cogon grass (*Imperata*). In Bhutan, found more in forest at lower elevations, where overlaps with *P. erythrogenys*; at higher elevations uses scrub and open conifer forest. Found at 1370–3050 m (locally 700–3300 m) in Indian Subcontinent, 915–2440 m in SE Asia; 1600–2775 m in Xizang, and 200–3400 m in rest of China.

**Food and Feeding.** Insects, including cicadas (Cicadidae), beetles (Coleoptera), ants (Formicidae), larvae and grubs; also seeds and berries. Shy. Usually in pairs, particularly during breeding season; otherwise in small parties of up to six individuals, sometimes in company with other species in mixed flocks. Usually forages near ground. Climbs about tree trunks; occasionally hangs upside-down, like woodpecker (Picidae) or nuthatch (Sittidae), on underside of moss-covered branch.

**Breeding.** Jan–Jul; multi-brooded. Nest a bulky, crude dome with entrance at side or near top, or a cone on its side, made of dry bamboo or other leaves, fern leaves, grasses, strips of bark, twigs, plant fibres, stems and roots, lined with rootlets, grasses, leaf skeletons, moss, stalks and fine fibres, placed on ground among grass, ferns or dead leaves, in recess in bank or on ledge, sometimes low down in small tree, bush or grass, rarely above 1 m. Clutch 2–5 eggs (usually 4 in India), white. No other information.

**Movements.** Resident; reported as winter visitor in Nagaland (NE India), but this improbable.

**Status and Conservation.** Not globally threatened. Fairly common in Nepal. Common and widespread at middle elevations in temperate zone in Bhutan. In India, locally common in W Himalayas, fairly common in E Himalayas, and locally common in NE hills; present in Buxa Tiger Reserve (West Bengal) and in and/or near Eaglenest Wildlife Sanctuary (Arunachal Pradesh), and in Barail Reserve Forest (Assam). Common in Natmataung National Park, in Myanmar. Abundant in parts of China, common at Emei Shan Protected Scenic Area (Sichuan), common in Shiwandashan National Nature Reserve and Diding Nature Reserve (Guangxi), and common in areas of Guangdong adjacent to Hong Kong; uncommon and localized population in Hong Kong of captive origin. Uncommon to common in SE Asian range. Present in Phou Dendin and Nakai-Nam Theun National Biodiversity Conservation Areas, in Laos. In Vietnam, present in Na Hang Nature Reserve and fairly common in Tam Dao National Park (in N), and in six protected areas in the Annamese lowlands.

## 74. Taiwan Scimitar-babbler

### *Pomatorhinus musicus*

**French:** Pomatorhin de Taiwan **German:** Taiwansäbler **Spanish:** Cimitarra de Formosa  
**Other common names:** Lesser Scimitar-babbler

**Taxonomy.** *Pomatorhinus* [sic] *musicus* Swinhoe, 1859, Taiwan.

Closely related to *P. ruficollis* and formerly treated as conspecific. Monotypic.

**Distribution.** Taiwan.

**Descriptive notes.** 19–21 cm; mean 40 g. Crown and nape are brown-tinged slaty grey with narrow white streaks on forehead, cutting sharply to rufous-chestnut mantle and neck sides (forming broad collar); remaining upperparts and upperwing mid-brown, greyish-brown tail; white supercilium from bill base above lores extending into upper edge of rufous collar; lores, cheek and ear-coverts black; chin, submoustachial area, throat and breast white, breast with evenly distributed large, broad black streaks, these changing colour on upper belly to chestnut on white; upper flanks and mid-belly chestnut, becoming dirtier and lower belly to brownish. Differs from similar *P. ruficollis* in somewhat larger size, proportionately longer bill with all-dark upper mandible, dark greyish crown, much broader and richer chestnut hindcollar, breast streaks brownish-black with clean-cut ovate pattern, and strongly chestnut-washed belly and lower flanks. Sexes similar. Juvenile apparently undescribed. Voice. Song variable, including rather husky “wuh-wuh-wuh-wree”, repeated every 5–9 seconds, quickly answered by jollier “wu-wit” (second note rising), also a hollow piping “uh-pu-pu-pu” (sometimes more hurried “wup’u’wu”) answered by low harsh husky “whéér-wu’wu”. Call (in Oct) a loud, rich, musical “tui-tui”, repeated fairly regularly at intervals; also a whistled, burry “jrr-jee”, second note rising.

**Habitat.** Inhabits undergrowth of foothill, submontane and montane forest in the *Ficus*–*Malilus*, *Malilus*–*Castanopsis* and *Quercus* zones, up to 2300 m; in N Taiwan, elevational limits are 15–2040 m.

**Food and Feeding.** Insects and seeds found in stomachs. Behaviour as in *P. ruficollis*. Usually in pairs during breeding season; also in small parties at other times. Usually forages near ground or around tree trunks.

**Breeding.** Apr–Jun. Clutch 3 eggs. No other information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Common. Recorded density of 0.03 birds/ha in mixed coniferous forest in Yushan National Park, although this not a preferred habitat.

**Bibliography.** Cheng Tsohsin (1987), Collar (2004, 2006), Collar *et al.* (2003), Ding Tsungsu *et al.* (1997), Hachisuka & Udagawa (1950, 1951), Koh Chaonien & Lee Peifen (2003), Kuroda (1917), Meyer de Schauensee (1984), Severinghaus & Blackshaw (1976), Yen Chungwei (1990).

## 75. Orange-billed Scimitar-babbler

### *Pomatorhinus ochraceiceps*

**French:** Pomatorhin à bec rouge **German:** Rotschnabelsäbler **Spanish:** Cimitarra Piquirroja  
**Other common names:** Red-billed/Long-billed Scimitar-babbler, Lloyd’s Scimitar-babbler, Ochraceous-headed Scimitar-babbler

**Taxonomy.** *Pomatorhinus ochraceiceps* Walden, 1873, Karen Hills, Upper Myanmar.

Four subspecies recognized.

**Subspecies and Distribution.**

*P. o. stenorhynchus* Godwin-Austen, 1877 – extreme NE India (E Arunachal Pradesh) and extreme N Myanmar.

*P. o. austeni* Hume, 1881 – NE India (Meghalaya E to Nagaland and S to Mizoram), SE Bangladesh and N Myanmar.

*P. o. ochraceiceps* Walden, 1873 – SE Myanmar (including N Tenasserim), NW Thailand, S China (S Yunnan) and N Indochina.

*P. o. alius* Riley, 1940 – N Thailand, S Laos and Vietnam (C & S Annam).

**Descriptive notes.** 22–24 cm; 33–38 g. Distinctive, with long decurved orange bill. Nominative race has crown and upperparts, upperwing and tail rufescent mid-brown; long supercilium white, lores (including nalar feathering) and cheek black, ear-coverts blackish-bronze; chin and submoustachial area to mid-belly white, flanks buffish, becoming greyer lower down and on thighs and vent; iris sandy yellow to dull pinkish-cream; bill orange to orange-red; legs slate-green or yellowish-brown. Distinguished from very similar *P. ferruginosus* by longer, more decurved, and orange bill. Sexes similar. Juvenile has shorter bill than adult. Race *austeni* is

duller than nominate, more olive-tinged above, wings pale brown, tail mid-brown, underparts off-white, flanks to vent tinged greyer. *stenorhynchus* is like nominate, but ear-coverts black, breast and belly warm buff. *alius* is like nominate, but tail darker above. Voice. Highly vocal; groups give a variety of mellow and harsh notes. Song a hurried staccato hollow piping “wu-wu-wu”, “wu-wu-wu”, “wu-wu-whip”, “pu-pu” or “koyou-dip”, and the like, sometimes answered (perhaps by female) with thin nasal downslurred “wyee” or “kveee”; also, very rapid “wi-wuwu” and loud whistled “u-wip”, repeated after pauses. When alarmed, gives short repeated bursts of harsh scratchy guttural rattles, e.g.

“whi-chutututut”, “whi-trrrrrt whi-trrrrrt”, “tchrrrrtutut tchrrrrt...”, variable sounds (often combined) when excited, include rapid purring “wrrrrrr”, clear “wuhu-wuhu”, nasal “woiee-woiee”, weak “whiu-whiu”, high “wheep”, harsh, dry short rising “whéesh!”, high rising “whi”, and steeply descending, buzzy nasal complaining “nyááh”, often interspersed with dry buzzy rising rattles.

**Habitat.** Broadleaf evergreen forest, bamboo clumps, in Laos also *Fokienia*-dominated forest. Found at 300–2400 m in India, usually above 1220 m in China, 230–1800 m in Myanmar, and 600–1600 m in Thailand and Vietnam.

**Food and Feeding.** Invertebrates, including snails, caterpillars and beetles (Coleoptera); also nectar and seeds. Keeps in pairs or parties of up to six or so individuals, often associating with *Gampsorhynchus* babblers and bird waves. Forages in understorey to middle storey; more arboreal than congeners, sometimes up to 12 m above ground. Also forages on ground, and probes into flowers of forest trees for nectar.

**Breeding.** Mar–Jul. Nest an oval ball made of broad grass blades, bamboo leaves and a few other dead leaves, loosely put together, lined with finer materials and rootlets, placed on ground, nearly covered by fallen leaves, or low down in undergrowth or creepers. Clutch 3–5 eggs, white. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon in NE hills in India; fairly common in Namdapha National Park (Arunachal Pradesh). Evidently very localized and rare in Bangladesh. Uncommon in China. Generally uncommon in SE Asian range. Uncommon in Nam Nao National Park, in Thailand. Common in Nam Kading and Dong Hua Sao National Biodiversity Conservation Areas (NBCAs) and in Nakai-Nam Theun NBCA, in Laos. In Vietnam, present in Na Hang Nature Reserve and common in Tam Dao National Park (in N), Thuong Da Nhim and Chu Yang Sin Nature Reserves (Da Lat Plateau, in S Annam), and Pu Mat and Vu Quang Nature Reserves in the Annamese Lowlands Endemic Bird Area.

**Bibliography.** Ali & Ripley (1948, 1971), Birand & Pawar (2004), Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paolai (1962), David-Beaulieu (1944), Davidson (1998), Deignan (1963), Delacour & Jabouille (1931a), Duckworth *et al.* (1998), Eames (1995), Eames *et al.* (2001), Engelbach (1932), Evans & Timmins (1998), Grimmett *et al.* (1998), Hill (2000), Hume & Davison (1878), Katti *et al.* (1992), Lê Manh Hùng *et al.* (2002), Lekagul & Round (1991), Mayr (1938), Meyer de Schauensee (1984), Nguyễn Đức Tu *et al.* (2001), Rasmussen & Anderson (2005), Ripley (1952), Robson (2000), Robson, Eames, Nguyễn Cú & Truong Van La (1993b), Robson, Eames, Wolstencroft *et al.* (1989), Round (1999), Showler, Davidson, Chanthavi Vongkhamheng & Khounmee Salivong (1998), Showler, Davidson, Khounmee Salivong & Khamkhoun Khounbolin (1998), Smith *et al.* (1943), Smythies (1986), Stanford & Mayr (1941), Stuart Baker (1901), Thewlis *et al.* (1996), Thompson & Johnson (2003), Tizard *et al.* (1997), Tordoff *et al.* (2002).

## 76. Coral-billed Scimitar-babbler

### *Pomatorhinus ferruginosus*

**French:** Pomatorhin à bec corail **German:** Korallen schnabelsäbler **Spanish:** Cimitarra Coralina

**Taxonomy.** *Pomatorhinus* [sic] *ferruginosus* Blyth, 1845, Darjeeling, India.

Nominate race perhaps better considered a separate species from other races on grounds of its different head pattern and crown-feather shape; such treatment possibly supported by vocal characteristics, but more samples needed. Races *stanfordi*, *formosus* and *phayrei* form a group. Proposed race *mariae* (from Toungoo Hills, in Myanmar) synonymized with *albogularis* owing to improbable distribution, but is slightly weaker buff below than latter and worthy of further investigation; *namdapha* (extreme E Arunachal Pradesh, in NE India) treated as synonym of *stanfordi*. Birds in C Laos paler below than *orientalis* and may represent an undescribed race. Seven subspecies currently recognized.

**Subspecies and Distribution.**

*P. f. ferruginosus* Blyth, 1845 – E Nepal E to NE India (C Arunachal Pradesh) and adjacent S China (SE Xizang).

*P. f. stanfordi* Ticehurst, 1935 – E Arunachal Pradesh, N Myanmar and S China (W Yunnan).

*P. f. formosus* Koelz, 1952 – NE India (Meghalaya E to Nagaland and Manipur).

*P. f. phayrei* Blyth, 1847 – Mizoram (NE India) and SW Myanmar.

*P. f. albogularis* Blyth, 1855 – S & SE Myanmar (including N & C Tenasserim), NW & W Thailand and NW Laos.

*P. f. orientalis* Delacour, 1927 – S China (SE Yunnan), NE Laos and N Vietnam (Tonkin, N Annam).

*P. f. dickinsoni* J. C. Eames, 2002 – S Laos and Vietnam (C Annam).

**Descriptive notes.** 24 cm; 40–48 g. Largish scimitar-babbler with white supercilium, black mask and medium-length red bill, underparts rich rufous in W of range, increasingly pale in E. Nominative race has crown, lores, cheek, ear-coverts and rear neck side black, with spray of pointed buff-based chestnut feathers above lores forming start of long white supercilium; upperparts warm olive-brown, upperwing and tail warm brown; chin, upper throat and submoustachial stripe (extending to lower neck side) white, lower throat, breast and mid-belly rich tawny-rufous, shading on lower underparts to ochrous-brown; iris golden-yellow to cream-

buff; bill deep coral-red or flame-scarlet; legs pale yellowish-brown. Sexes similar. Juvenile is more rufescent above and below than adult. Race *formosus* has crown concolorous with upperparts (except for narrow black upper edge of supercilium), lacks elongate or different-coloured feathers on forehead, underparts paler and buffier; *phayrei* is like previous, but slightly more olive above, paler below. *stanfordi* is like last, but browner above, paler (creamy buff) below, with bolder black lateral crownstreaks meeting on forehead; *albogularis* resembles previous but richer, more rufescent-brown, above, slightly warmer buff below; *orientalis* is like previous, but richest brown above of all races; *dickinsoni* is slightly more olive above than last, and almost entirely white below, with flanks vaguely buff or olive-brown. Voice. Apparent song of nominate a loud, piercing, rich, slightly burry, slurred “fiéwufiéw”, reminiscent of that of Large Hawk-cuckoo (*Cuculus sparverioides*) but more deliberate, with different rhythm; varied by slightly raspier, slower “fu-fiéwufiéw”, “fi-fiéwufiéw”, and sweet slurred whistles of 1–3 notes suggesting an oriole (*Oriolus*), e.g. “wheeeer” or “twheeeer”. In SE Asia several birds may unite to produce wide variety of sounds, including soft, questioning “whu”, “whiu” and “whoiee”, meowing “whheeeer”, shrill yelping “yep-yep-yep...” and short squeaky notes, along with more typical hawk scolding “whit-whit-tehrrrrt”, “tehrrrt-tehrrrrt” and “whitchitt”, etc.; also a scratchy “weeitch-oo” and shrill “wheep-wheep”; clear whistled “ch-wooa” also recorded. Calls of nominate include subdued murmuring descending laughing, and explosive whinash with much softer, hissing rattle, “weesh-sh-sh”.

sh'sh'sh'sh"; in SE Asia, when alarmed, gives harsh dry "krrrrt", "krururutt" or "krrrrrrurur", less scratchy and piercing than equivalent call of *P. ochraceiceps*.

**Habitat.** Broadleaf evergreen forest, bamboo, secondary growth, wild banana groves in gulleys, but in Bhutan associated with areas of continuous forest and absent from more fragmented forests (yet still seems to select denser patches of vegetation with much bamboo where landslides have broken up continuous canopy). In Nam Theun watershed, in Laos, common in dry evergreen forest at 1000–1400 m but commoner in *Fokienia*-dominated forest at 1400–1800 m. Found at 400–2400 m in Indian Subcontinent; 1000–2000 m in Bhutan, 800–2285 m in SE Asia and China.

**Food and Feeding.** Insects and larvae; observed also to peel off and swallow thin strips of bamboo. Very elusive, found in pairs or small parties, rummaging on ground among fallen leaves, moving from cover to cover in big hops; reluctant to fly. Sometimes in association with mixed feeding flocks. Ascends to lower storey.

**Breeding.** Apr–Aug. Nest sometimes attended by three birds (Laos). Nest an oval or bulky cone placed on side, made of dry bamboo, rattan or other leaves, grasses, plant fibres and stems, creepers, twigs, fern fronds, and tendrils, lined with fibrous strips of bamboo, rootlets and fine grasses, placed on ground, sometimes on natural mound, or low down among stalks and leaf litter, in bush, sapling, tangled grass or bamboo clump, sometimes as high as 2 m above ground. Clutch 3–5 eggs (usually 3 in Myanmar), white. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare in Nepal: known only from sightings in Arun valley in 1973. Uncommon and local in Bhutan, although possibly overlooked; but more thinly spread than either *P. erythrogeus* or *P. ruficollis*. Rare in W of range in India, but locally frequent in E; present in Buxa Tiger Reserve (West Bengal) and Eaglenest Wildlife Sanctuary and Namdapha National Park (Arunachal Pradesh). Rare in China. Generally uncommon in SE Asian range. Uncommon in Doi Inthanon National Park, in Thailand. In Laos, present on Bolovens Plateau in Dong Hua Sao National Biodiversity Conservation Area (NBCA), and in Phou Dendin NBCA, and common in Naka-Nam Theun NBCA. Present in Pu Mat and Vu Quang Nature Reserves and fairly common in Tam Dao National Park, in Vietnam.

## Genus *SPHENOCICHLA*

Godwin-Austen & Walden, 1875

### 77. Blackish-breasted Babbler

#### *Sphenocichla humei*

**French:** Timalie à gros bec **Spanish:** Ratina Picocuña Occidental  
**German:** West-Keilschnabeltimalie  
**Other common names:** Western/Sikkim Wedge-billed Babbler; Wedge-billed Babbler/Wren-babbler (when treated as conspecific with *S. roberti*)

**Taxonomy.** *Heterorhynchus Humei* Mandelli, 1873, Sikkim, India. Formerly treated as conspecific with *S. roberti*, but song different. Monotypic.  
**Distribution.** Extreme E Nepal, Sikkim and N West Bengal E to Bhutan and NE India (NE Arunachal Pradesh).

**Descriptive notes.** 18 cm. Blackish babbler with wedge-shaped bill, and subtle plumage pattern of buff streaks above and minute grey scaling below. Entire upperside is blackish-brown, each feather internally buff, those of lores and forehead with whitish shaft streaks, those of mid-crown to mantle with bright buff shaft streaks and well-separated barbs, those of back to uppertail-coverts similar but duller buff-brown and with narrow blackish-brown bars; upperwing and tail shinier blackish-brown with dull brown barring; head side has reduced internal markings on lateral crown (producing effect of vague blackish lateral

crownstripe), whitish postocular supercilium breaking up on neck side into series of whitish streaks; rest of face (ear-coverts, cheek, submoustachial area) and chin blackish-brown with whitish shaft streaks, throat to upper belly similar but streaks greyer and with very narrow pale stone-grey edges (producing barely perceptible scaling), central belly irregularly stone-grey, lower flanks, lower belly, thighs and vent scaled buffy-ochre and blackish-brown; iris colour apparently undescribed (dark brown in photo); bill pale bluish slaty, base darker; legs powerful, dark brown. Sexes similar. Juvenile apparently undescribed. **Voice.** Songs include loud, melodious, piping, slurred whistles, often given in duet; types include short subdued notes followed by quick liquid fluty whistles that are slurred steeply up and down, "twittwittwhitt-fúwééféwéoo", sometimes more hurried and squealed, or may start near top and quickly warble downwards. Calls include strident, peevish, deliberately paced set of whistles, "chyuuw, chéét-chéét, chéét"; alarm a subdued low "hrrrr hrrrr hrrrr hrrrr it hrrrr hrrrr..."

**Habitat.** Floor and understorey of broadleaf evergreen forest, bamboo brakes; in Bhutan prefers tall broadleaf forest with W-facing aspect. At 900–1950 m; in Bhutan, present at 1600 m and 1950 m in breeding season, at 1100 m in winter.

**Food and Feeding.** Few details available. Relatively arboreal at times. Often hunts in quite dense undergrowth near streams. Habits thought to be similar to those of *S. roberti*.

**Breeding.** No information available.

**Movements.** Resident; seasonal elevational movement inferred in Bhutan requires substantiation.  
**Status and Conservation.** Not assessed. When lumped with *S. roberti*, considered Near-threatened. Restricted-range species: present in Eastern Himalayas EBA. In Nepal, so far only recorded from Dharan district. Rare in Bhutan, but discovered there as recently as 2000, and one site (Kuri Chhu valley, inside Thrumshingla National Park) may harbour significant population; most of probable range, however, lies outside protected areas and this species' future in the country will depend on forest management practices. Status in India uncertain, but recorded in Namdapha National Park and Mehao Wildlife Sanctuary, in Arunachal Pradesh. Although forest within its elevational range is relatively secure, shifting cultivation and logging are reducing forest cover at lower levels.

**Bibliography.** Ali & Ripley (1971), Anon. (2006d), Boetticher (1930), Butchart & Stattersfield (2004), Choudhury (2000), Collar (2006), Collar *et al.* (2001), Grimmett *et al.* (1998), Inskipp *et al.* (2000), Karki & Choudhury (1997), Katti *et al.* (1992), Lightfoot (1939), Mandelli (1873), Rasmussen & Anderton (2005), Singh (1995), Spienberg (2005), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stevens (1924).

### 78. Chevron-breasted Babbler

#### *Sphenocichla roberti*

**French:** Timalie de Robert **Spanish:** Ratina Picocuña Oriental  
**German:** Ost-Keilschnabeltimalie  
**Other common names:** Cachar/Eastern Wedge-billed Babbler; Wedge-billed Babbler/Wren-babbler (when treated as conspecific with *S. humei*)

**Taxonomy.** *Sphenocichla roberti* Godwin-Austen and Walden, 1875, North Cachar and Manipur Hills, India.

Formerly treated as conspecific with *S. humei*, but song different. Monotypic.  
**Distribution.** NE India from E Arunachal Pradesh (Mishmi Hills) S to Assam (N Cachar, Margherita), Nagaland and N Manipur; N Myanmar and adjacent S China (NW Yunnan).

**Descriptive notes.** 18 cm: 29–43 g. Similar in size to *S. humei*, and with same pointed and conical bill, but paler owing to very different, though equally subtle, plumage pattern; bill slightly larger and tail shorter. Lores to mid-crown are rusty brown with darker edging, shading on hindcrown to uppertail-coverts to warm buff-brown with blackish-brown fringes, most with whitish inner fringes (making for slightly chevron-shaped scaled effect); weaker and rustier on rear upperparts, upperwing and tail barred blackish-brown and dull brown (appearing paler than *S. humei*, because dark bars

narrower); head side mainly whitish-grey with dark brown scaling, partial whitish ceyring strongest above eye, where extends back as whitish postocular supercilium, ear-coverts plain brown with pale shaft streaks; elaborate pattern from chin to breast and flank sides of triangular (chevron-shaped) scales involving broad buffy-brown feather centres, stony-white inner fringes in pointed "V", and dark outer fringes (barb extensions), lower underparts losing pattern as buffy brown predominates; iris rich brown to dark crimson; bill blackish-brown with horn-grey tip, lower mandible bluish basally; legs powerful, dark brown. Sexes

similar. Juvenile apparently undescribed; museum specimen with rustier forehead, little or no barring on wings and rustier posterior upperparts and underparts may be immature. **Voice.** Song a clear, loud, fluty, melodious "uu-wii-wu-yu" ("wii" highest, "yu" lowest), lasting 1.1–1.2 seconds and repeated every 6–17 seconds; very different from that of *S. humei*. Calls apparently similar to those of latter.

**Habitat.** Evergreen forest with large trees and bamboo on edge of dense jungle, at 300–2010 m.

**Food and Feeding.** Woodlice (Isopoda), small boring beetles (Coleoptera) and other insects. Found in parties of 10–15 individuals. Relatively arboreal at times; active climber about rough bark of bigger trees, though not higher branches. Often hunts in quite dense undergrowth near streams.

**Breeding.** May–Jun. Nest reportedly a pad of moss on top of mass of fine grasses and a few tendrils and bents, no lining other than soft moss, wedged behind long hanging slip of bark (built at bottom of long crevice) 6.5 m above ground on oak tree. Clutch 4 eggs, white. No other information.

**Movements.** Resident; report of seasonal elevational movements in Assam requires substantiation.

**Status and Conservation.** Not assessed. When lumped with *S. humei*, considered Near-threatened. Generally scarce. Scarce in Namdapha National Park (Arunachal Pradesh), in India. Judged very rare in China. Although forest within its elevational range is relatively secure, shifting cultivation and logging are reducing forest cover at lower levels. In India, seen to be traded as food (dead bird) in Kohima (Nagaland) in 1997.

**Bibliography.** Ali & Ripley (1971), Choudhury (2000, 2001), Collar (2006), Godwin-Austen & Walden (1875), Grimmett *et al.* (1998), Han Lianshan (1992), King *et al.* (2001), Rasmussen & Anderton (2005), Ripley *et al.* (1991), Robson (2000), Smythies (1949, 1986), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stuart Baker (1894), Ticehurst (1939).

## Genus *SPELAEORNIS* David & Oustalet, 1877

### 79. Bar-winged Wren-babbler

#### *Spelaeornis troglodytoides*

**French:** Timalie troglodyte **German:** Binden-Zaunkönigstimalie **Spanish:** Ratina Aliharrada  
**Other common names:** Long-tailed Spotted Wren-babbler

**Taxonomy.** *Phoeopyga troglodytoides* J. Verreaux, 1870, "les montagnes du Thibet chinois" = Muping [Paohing], south-east Xizang, China. Seven subspecies recognized.

**Subspecies and Distribution.**

- S. t. sherriffi* Kinnear, 1934 – E Bhutan and adjacent NE India (W Arunachal Pradesh).
- S. t. indiraji* Ripley *et al.*, 1991 – SE Arunachal Pradesh (Namdapha National Park), in NE India.
- S. t. souliei* Oustalet, 1898 – NC Arunachal Pradesh (NE India) E to N Myanmar and S China (NW Yunnan W of R Salween).
- S. t. rocki* Riley, 1929 – NW Yunnan (E of R Salween).
- S. t. halsueti* (David, 1875) – C China (S Gansu, S Shaanxi, N & NE Sichuan).
- S. t. nanchuanensis* Li Guiyuan *et al.*, 1992 – SC China (C Sichuan, Hubei, Hunan).
- S. t. troglodytoides* (J. Verreaux, 1870) – S China (SW & WC Sichuan S to extreme NE Yunnan and N Guizhou).

**Descriptive notes.** 10 cm. Long-tailed, rufous-brown wren-babbler with white-spotted blackish head, white breast, barred wings and tail. Male nominate race has crown and nape blackish, tinged rufous and heavily spotted white, lores, cheek and ear-coverts deep orange-buff; upperparts umber-brown, each feather with white subterminal bar and black tip (creating heavy spotting effect), upperwing and tail narrowly barred whitish and black; throat white, underparts dull rufous, white streaks extending from throat to breast; iris red-ochre to brown; bill brown or blackish-horn, paler lower mandible; legs horn-brown or olive. Female

has more rufous-streaked throat, more extensive and brighter rufous below. Juvenile is much darker than adult, blackish-brown above, with reddish-buff streaks on crown and bars on back, barring on wings and tail less coherent, more vermiculate. Races differ mainly in pattern and tone of plumage: *nanchuanensis* is less strongly spotted above than nominate, with no white throat; *halsueti* has upperparts greyish-brown, cheek and ear-coverts pale orange-buff; *sherriffi* has white of breast extending brokenly onto belly and there tipped dark; neck side and flanks browner, whiter markings on neck side, juvenile with throat and belly whitish; *indiraji* has crown and nape blackish with mix of pale spotting and fine barring of grey-brown (forming distinct cap), uppertail and wings washed dull brownish-grey, tail barred grey and black, flanks deep rufous; *canis* has cheek and

On following pages: 80. Rufous-throated Wren-babbler (*Spelaeornis caudatus*); 81. Rusty-throated Wren-babbler (*Spelaeornis hadaogularis*); 82. Naga wren-babbler (*Spelaeornis phoeniceus*); 83. Grey-bellied Wren-babbler (*Spelaeornis reptans*); 84. Pale-throated Wren-babbler (*Spelaeornis kincairdi*); 85. Tawny-breasted Wren-babbler (*Spelaeornis longicaudatus*); 86. Chin Hills Wren-babbler (*Spelaeornis ostesi*); 87. Spotted Wren-babbler (*Elachura formosa*); 88. Scaly-breasted Wren-babbler (*Phoeopyga albiventer*); 89. Taiwan Wren-babbler (*Phoeopyga formosana*); 90. Nepal Wren-babbler (*Phoeopyga immaculata*); 91. Pygmy Wren-babbler (*Phoeopyga pusilla*).

ear-coverts brown with buff shaft streaks, greyish-brown upperparts, white of throat heavily obscured with brown and rufous, juvenile underparts dull rufous; *rocki* has cheek and ear-coverts brown with buff shaft streaks, paler neck side and underparts. Voice. Song a repeated husky rapid rolling warble of 5–8 notes, "ch'whi-whi-whi-whi-whi-whi-whi" or "ch'whi-whi-whi-whi"; series also reported as starting with longer, strongly upslurred note and ending with shorter, lower and quieter note than first, regularly repeated at intervals of 2–3 seconds.

**Habitat.** Dense undergrowth and bamboo thickets in moist cool temperate forest, including deciduous, rhododendron, oak, mixed hemlock-broadleaf and fir forest. Found at 2300–3500 m in Indian Subcontinent, 2440–2895 m in Myanmar, and 1600–2440 m in China.

**Food and Feeding.** Insects, including beetles (Coleoptera). Sometimes in small groups up to six individuals, even in late Apr (breeding period). More arboreal than most wren-babblers, clambering about on bamboo stems and mossy tree trunks, up to 1.5 m above ground.

**Breeding.** Season Mar–Jun. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally rare over most of range. Uncommon in Bhutan, where known mainly from forest between Sengor and Namling (Mongar district), with occurrence in other areas rather unpredictable; most records are from within protected areas, including Thrumshingla National Park. Rare in India, where present in and/or near Eaglenest Wildlife Sanctuary (Arunachal Pradesh). Scarce in Myanmar. Rare and local in China; scarce at Emei Shan Protected Scenic Area, in Sichuan.

**Bibliography.** Ali & Ripley (1971), Cheng Tsohsin (1987), Choudhury (2003), Deditius (1897), Dowell *et al.* (1997), Greenway (1933), Grimmer *et al.* (1998), Inskipp *et al.* (2000), Li Guiyuan *et al.* (1992), Ludlow & Kinnear (1937, 1944), Meyer de Schauensee (1984), Rasmussen & Anderton (2005), Riley (1926), Ripley *et al.* (1991), Robson (2000), Rothschild (1926), Singh (1995), Smythies (1949), Spienberg (2005), Stanford (1941), Stanford & Mayr (1941), Wang Zhijun & Wei Tianhao (1983), Wu Zhikang *et al.* (1986), Zheng Zuoxin & Qian Yanwen (1973).

## 80. Rufous-throated Wren-babbler

### *Spelaeornis caudatus*

**French:** Timalie à gorge rousse **German:** Rotkehl-Zaunkönigstimalie **Spanish:** Ratina Golirrufa  
**Other common names:** Tailed/Short-tailed Wren-babbler

**Taxonomy.** *Tesia*, *caudata* Blyth, 1845, Darjeeling, India.

May form a superspecies with *S. badeigularis*; often treated as conspecific, but recent museum and field studies support treatment as separate species. Monotypic.

**Distribution.** E Nepal E to NE India (W Arunachal Pradesh).

**Descriptive notes.** 9 cm; 10–12 g. Small brown wren-babbler with rusty throat and breast and dark, white-spotted belly. Crown to lower back are darkish brown with indistinct darker brown scaling, fluffy feathers of rump plainer dark brown, upperwing and tail plain dark brown, former with slight rusty fringes; face (forehead, lores, ear-coverts and submoustachial area) plain brownish-tinged grey, chin to breast and flanks plain rusty rufous, becoming increasingly spotted with black on breast and flanks such that lower underparts become slaty while rufous becomes spotted and shades to whitish on mid-belly to vent; iris brown; bill blackish;

legs brown. Sexes similar. Juvenile is plainer than adult, more reddish above without scalloping, rusty colour of throat paler and barring indistinct. Voice. Song a powerful, jangling short outburst, "witchu-witchu-witchu-witchu", first note slightly higher; also a slightly more trisyllabic "whitchu-..." or with first note slightly drawn out. Alarm a low "birrh birrh birrh", uttered for rather lengthy periods when disturbed; calls a soft "churrp", "chip" or "chitturp", much softer than typical call of *Pnoepyga*, sometimes in series as soft, liquid churring rattle; while foraging, may continually give these calls as subdued muttering.

**Habitat.** Dense thickets and undergrowth in moist broadleaf evergreen forest, in secluded valleys and steep narrow gulleys, especially where ferns, mossy rocks and fallen trees abound, and commonly with a W or N aspect. Elevational range in Bhutan 1400–2400 m, suggesting close link with ecotone between warm and cool broadleaf-forest zones; 1800–2400 m in India, 2135–2440 m in Nepal.

**Food and Feeding.** Insects. No other information.

**Breeding.** Little known, and published records not entirely reliable. Song period in Bhutan mid-Mar to mid-May, with second period in early Aug. Nest described as made of leaves, fine twigs, bracken and grass, lined with vegetable down or other matter, resembling earth-brown papier-mâché, or as dense mass of moss, cup-shaped and placed about roots of tree or in hole in fallen log. Clutch said to be of 3–4 eggs, white with reddish spots (as those of *S. longicaudatus*).

**Movements.** Resident, with minor altitudinal movements.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species; present in Eastern Himalayas EBA. Very rare in Nepal, with no known records since 1993. In Bhutan, probably the key country for the species (given its small range and habitat needs), frequently recorded, mainly through song; present in Thrumshingla National Park, where stronghold in forests between Namling and Yonkhola, with 4–8 territories along 24 km of road at suitable elevations, and at one site in Jigme Singye Wangchuck National Park. Locally common in India, where present in and/or near Eaglenest Wildlife Sanctuary (Arunachal Pradesh). At risk from destruction and fragmentation of forest within its small range, chiefly through logging and shifting cultivation, but probably more widespread and abundant than current records imply.

**Bibliography.** Ali & Ripley (1971), Anon. (2006d), Bishop (1999), Butchart & Stattersfield (2004), Choudhury (2003), Collar (2006), Collar *et al.* (2001), Grimmer *et al.* (1998), Inskipp & Inskipp (1991), Inskipp *et al.* (2000), Ludlow & Kinnear (1937, 1944), Mariens & Eick (1995), Rasmussen & Anderton (2005), Singh (1995), Spienberg (2005), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stevens (1924).

## 81. Rusty-throated Wren-babbler

### *Spelaeornis badeigularis*

**French:** Timalie des Mishmi **German:** Mishmi-Zaunkönigstimalie **Spanish:** Ratina Mishmi  
**Other common names:** Mishmi Wren-babbler

**Taxonomy.** *Spelaeornis badeigularis* Ripley, 1948, Dreyi, Mishmi Hills, north-eastern Assam, India.

May form a superspecies with *S. caudatus*; often treated as conspecific, but recent museum and field studies support treatment as separate species. Monotypic.

**Distribution.** E Arunachal Pradesh (Mishmi Hills), in NE India.

**Descriptive notes.** 9 cm. Very similar to *S. caudatus*, but has darker upperparts, darker grey ear-coverts, white chin and upper throat, chestnut lower throat and breast with dark-streaked feather centres (chestnut not running to flanks), dark brown flanks and vent, more barring on underparts, and longer, stouter tarsus; when singing, exhibits distinct whitish crescent on lower edge of chestnut breast; iris brown; bill black; legs brown. Sexes similar. Juvenile apparently undescribed. Voice. Song highly variable, ranging from simple 3-note or 4-note whistle or short complex warble to combination of short warble and short trill, all

involving short staccato musical whistles, and generally much less structured than that of *S. caudatus*: sudden, rapid, explosive "chipichiwichichit" or "chipihuwichichit" repeated after intervals of 5–22 seconds, also shorter outbursts of "whi'chitu" or "whi'pichu" and "chu'wit-w'ch'ch'ch'ch" (quick introduction followed by trill). Each individual appears to have repertoire of at least three songs.

**Habitat.** Only specimen was in subtropical wet forest in winter at 1600 m. Recently relocated in mostly secondary broadleaf evergreen forest at 1700–2400 m, when present in dense low undergrowth 1–3 m tall with usually broken canopy of trees.

**Food and Feeding.** Insects. Recently observed individuals kept mostly within 1 m of ground.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** VULNERABLE. Restricted-range species; present in Eastern Himalayas EBA. Since its initial discovery, in late 1940s, was not seen again in 20th century, doubtless because of problems over access to its only known site of occurrence. Subsequently, observations in 2004 in Mishmi Hills (specifically on Roing–Hunli road, on both N & S sides of Mayodia Pass) revealed that, with tape playback, as many as eight different individuals could be triggered into singing along 3 km of road, indicating substantial abundance within highly limited known range. Subtropical forest in Dibang and Lohit districts in S Mishmi Hills is disappearing owing to timber extraction. Species possibly occurs in Mehao Wildlife Sanctuary, in Mishmi Hills, and possibly nearby at site such as Mouling National Park.

**Bibliography.** Ali & Ripley (1948, 1971), Anon. (2006d), Butchart & Stattersfield (2004), Collar (2006), Collar *et al.* (2001), Grimmer *et al.* (1998), King & Donahue (2006), Rasmussen & Anderton (2005), Ripley (1948, 1950a), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

## 82. Naga Wren-babbler

### *Spelaeornis chocolatinus*

**French:** Timalie chocolat **German:** Langschwanz-Zaunkönigstimalie **Spanish:** Ratina Chocolate  
**Other common names:** Austen's/Streaked/Long-tailed Wren-babbler, Streaked Long-tailed Wren-babbler

**Taxonomy.** *Pnoepyga chocolatina* Godwin-Austen and Walden, 1875, Kedimai, Manipur, India. Formerly treated as conspecific with *S. reptatus*, *S. kinneari* and *S. oatesi*. Monotypic.

**Distribution.** Nagaland and N Manipur, in NE India.

**Descriptive notes.** 10 cm; 11–15 g. Small dark wren-babbler with strong buffy streaks on brownish flanks. Male has crown to rump slightly warm olive-brown with darker fringes (vague scaly effect), plain upperwing and medium-length tail slightly more rufescent; lores and ear-coverts olive-tinged buffish-grey, chin pale buffy, shading to rich ochrous-brown on breast, flanks and belly with small buffy dots and dark marks and, on flanks, broad-ended buffy shaft streaks, mid-belly flecked with white; iris reddish-brown; bill dark brown, paler tip; legs fleshy-brown to light brown. Female is more rufescent above and below.

Juvenile apparently undescribed. Voice. Undescribed.

**Habitat.** Inhabits montane broadleaf evergreen forest with undergrowth of bracken, ferns or *Strobilanthes*, on steep hillsides broken with rocks and large boulders covered with rich vegetation and green moss, and thick low (often thorny) bushes, briars and dwarf bamboo, especially at edge of evergreen forest and in clearings; often in dense undergrowth near water. Found at elevations of 1200–3100 m.

**Food and Feeding.** Diet includes ants (Formicidae), small beetles (Coleoptera) and other insects. Very active; often found up to 0.6 m above ground, and not so exclusively ground-dwelling as *Pnoepyga*.

**Breeding.** One reported nest, in May, a deep cup with long back wall (though not enough to form roof), made of leaf skeletons bound together with dark, coarse fern roots, grass bents, and fine elastic twigs, lined with leaf skeletons, placed on pile of dead leaves, twigs and branches under fallen log. Clutch 3 eggs, white with very pale reddish marks, especially near broad end. No other information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Conservation status warrants review following recent taxonomic split, as species is scarce and highly restricted in range.

**Bibliography.** Ali & Ripley (1971), Collar (2006), Godwin-Austen & Walden (1875), Grimmer *et al.* (1998), Rasmussen & Anderton (2005), Ripley (1952), Stuart Baker (1922).

## 83. Grey-bellied Wren-babbler

### *Spelaeornis reptatus*

**French:** Timalie de Bingham **German:** Graubauch-Zaunkönigstimalie **Spanish:** Ratina Ventrigris

**Distribution.** Extreme NE India (E Arunachal Pradesh), N & E Myanmar, S China (NW & W Yunnan) and W Thailand.

**Bibliography.** Bingham (1903), Cheng Tsohsin (1987), Collar (2006), Harington (1909, 1914a), Meyer de Schauensee (1984), Rasmussen & Anderton (2005), Ripley *et al.* (1991), Robson (2000), Round & Pattanavibool (2003), Smythies (1940, 1986), Stanford & Mayr (1941), Stanford & Ticehurst (1935, 1938).

**French:** Timalie de Kinnear **German:** Blasskehl-Zaunkönigstimalie **Spanish:** Ratina Gorjipálida

**Status and Conservation.** Not assessed. Locally common within small range, although judged rare in China. Present in Fan Si Pan National Park, in Vietnam. In China, first recorded in NW Guangxi in May 2002, when four wren-babblers observed in Cenwanglaoshan Nature Reserve believed to belong to this species.

ar (2006), Harington (1909, 1914a), Meyer de Schauensee (1935), Robson (2000), Round & Pattanavibool (2003), Smythies (1935, 1938).

**Descriptive notes.** 11–12 cm. Small dark wren-babbler with pale throat. Male is dark bronzy brown with black scaling above, becoming plainer and more deep ochrous-brown on fluffy rump feathers; upwearing and tail dark brown with slight rufous tinge; head side dark brownish-grey with vague blackish-brown preocular patch and submoustachial area; chin and throat dirty white with some vague mid-brown mottling, this becoming stronger on upper breast and changing rapidly to deep bronzy-grey underparts with blackish scaling and a few white tips (most grey down centre of underparts, most bronzy brown on

very common within small range, although judged rare, in Vietnam. In China, first recorded in NW Yunnan, it has been observed in Cenwangaoshan Nature Reserve

below. Male has crown, submoustachial area and malar area connecting to neck side and upperparts olive-brown with darker fringes (creating rather dense but vague scaly effect), plain upperwing and tail slightly more rufescent; lores and ear-coverts olive-buff; chin to lower belly white with dark brown spots. Flanks olive-brown with buff and dark spots, thighs and vent plain olive-brown; iris brown; bill blackish; legs brown. Female is very like male, but slightly duller white below. Juvenile

**Food and Feeding.** Food presumably small invertebrates. Usually seen foraging within 0.5 m of ground.

Bibliography: Collar (2006), Grinnett *et al.* (1998), Rasmussen & Anderton (2005), Robson (2000), Smythies (1940, 1986), Siresmann & Heinrich (1940a), Thei Zaw Naing (2003).

Genus *ELACHURA* Oates, 1889

### 87. Spotted Wren-babbler

*Elachura formosa*

**French:** Timalie tachetée **German:** Fleckenbrust-Zaunkönigstimalie **Spanish:** Ratina Moteada  
**Other common names:** Spotted Short-tailed Wren-babbler, Spotted Wren

**Distribution.** E Nepal E to NE Indian hill states, NE Bangladesh, N & W Myanmar, SE China (W, C & SE, Yunnan E to Hunan, NW Fujian and N Guangdong), N & C Laos and N Vietnam (W Tonkin, N Annam).

**Bibliography.** Ali & Ripley (1971), Birand & Pawar (2004), Bishop (1999), Cheng Tsohsin (1987), Choudhury (2000), Davidson (1998), Dymond (2002), Farnes *et al.* (2001), Evans & Timmins (1998), Grimmer *et al.* (1998), Inskip & Inskip (1991), Inskip *et al.* (2000), King *et al.* (2001), La Touche (1899), Lewthwaite (1996), Ludlow & Kinnear (1937), Meyer & Schauenstein (1984), Rasmussen & Anderson (2005), Robson (2000), Robson *et al.* (1998), Singh (1995), Smythies (1986), Spierenburg (2005), Stresmann & Heinrich (1940a), Thewlis *et al.* (1998).

Genus *PNOEPYGA* Hodgson, 1844

## 88. Scaly-breasted Wren-babbler

*Pnoepyga albiventer*

**Taxonomy.** [*Tesia*] *Albiventer* Hodgson, 1837, Ilam District, eastern Nepal. Formerly treated as conspecific with *P. formosana*. Two subspecies recognized.

*P. a. albiventer* (Hodgson, 1837) – EC Nepal E to Bhutan and NE Indian hill states (except Meghalaya), S & SC China (S & SE Xizang, N & C Sichuan S to NW Yunnan), N & W Myanmar and N Vietnam (W Tonkin).

**Bibliography.** Ali & Ripley (1971), Allen *et al.* (1997), Birand & Pavar (2004), Cheng Tsohsin (1987), Cheng Tsohsin *et al.* (1963), Choudhury (2003), Collar (1996), Dowell *et al.* (1997), Gaston *et al.* (1994), Godwin-Austen (1870), Grimm *et al.* (1998), Huang Qiang *et al.* (1993), Inskipp & Inskipp (1991), Inskipp *et al.* (2000), King (1989b), Koezl (1954), Li Guiyuan *et al.* (1976), Ludlow (1951), Ludlow & Kinner (1937, 1944), Martens & Eek (1991, 1995), Meyer de Schauensee (1964), Mohan (1997), Pandey *et al.* (1994), Rasmussen & Anderson (2005), Ripley (1952), Robson (1986, 2000), Singh, A.P. (2000), Singh, P. (1995), Smythies (1940, 1949), Spicrenburg (2005), Stanford (1941), Stanford & Mayr (1941), Stevens (1924), Stresemann & Heinrich (1940a), Stuart Baker (1894), Tynstra (1993), Zheng Xuoxin *et al.* (1983).

## 89. Taiwan Wren-babbler

*Pnoepyga formosana*

**Habitat.** Dense tangled undergrowth and bamboo in montane broadleaf evergreen and mixed broadleaf-coniferous forest, at 1200–2700 m; elevational limits in N Taiwan 1475–2780 m.

**Descriptive notes.** 7.5–8 cm; 11–15 g. Tiny, almost tailless olive-backed babobird with pale scaling below; in two morphs. Nominative race pale morph ("white-scaled") is greyish olive-brown from crown to rump with slight dark scaling, upperwing brownier, small buffy subterminal spots on scapulars, wing-coverts and tertials; head side greyish olive-brown, ear-coverts with indistinct pale shaft streaks, chin and throat off-white with narrow grey-brown scaling, breast and belly off-

# Genus *STACHYRIDOPSIS* Oates, 1883

## 92. Golden Babbler

### *Stachyridopsis chrysaea*

**French:** Timalie dorée **German:** Goldkopftimalie **Spanish:** Timalí Dorado  
**Other common names:** Golden-headed Babbler

**Taxonomy.** *St[achyris]. chrysaea* Blyth, 1844, Nepal. Genus formerly merged with *Stachyris*. Geographical variation poorly defined, and characters separating most of the races very weak; revision probably needed. Populations in N Thailand, S Laos and C Vietnam (C Annam) not yet assigned to race. Six subspecies tentatively recognized.

#### Subspecies and Distribution.

- S. c. chrysaea* (Blyth, 1844) – C Nepal E to Bhutan, NE Indian hill states (except E Mizoram), N & NE Myanmar and adjacent S China (SE Xizang, NW & W Yunnan).
- S. c. binghami* (Rippon, 1904) – E Mizoram (NE India) & W Myanmar.
- S. c. aurata* (Meyer de Schauensee, 1938) – extreme E Myanmar, NW Thailand (S to Chiang Dao), N & C Laos, N Vietnam (Tonkin, N Annam) and S China (S Yunnan E to SW Guangxi).
- S. c. assimilis* (Walden, 1875) – SE Myanmar (including Tenasserim) and NW & W Thailand.
- S. c. chrysops* (Richmond, 1902) – S Thailand and Peninsular Malaysia.
- S. c. frigida* (Hartlaub, 1865) – Sumatra.

**Descriptive notes.** 10–12 cm; 6–10 g. Distinctive small babbler with narrowly striped crown, black half-mask and yellow underparts. Nominate race has crown and nape golden-yellow, narrowly and evenly streaked with black, with strong yellow preocular lateral crownstripe bordering black on lores and short black supercilium; upperparts yellowish-olive, upperwing and tail brownish-grey, flight-feathers with narrow yellow-buff fringes; short black submoustachial stripe from lores, plain yellowish-olive ear-coverts; chin to mid-belly bright yellow, shading on sides and below to olive-yellow; iris red or red-brown to brown or

brown-grey; bill blackish, paler below, often with pinkish-red or pinkish-flesh base of lower mandible; legs pale yellowish-brown to light brown. Sexes similar. Juvenile is duller and browner above than adult, whiter below, with browner flanks. Race *binghami* is more greyish-olive above than nominate, weaker yellow below, ear-coverts dark grey; *aurata* is smaller, with yellowish ear-coverts, less distinct head pattern, paler below; *assimilis* is very like previous, but ear-coverts more greyish-olive, underparts slightly brighter; *frigida* differs from last in greener upperparts, much less deeply yellow crown, pale yellow underparts, dusky olive-green sides of body; *chrysops* is intermediate between preceding two, but more like first of them (*assimilis*). Voice. Song a rapid “tu-tu-tu-tu-tu-tu” or slower “ti-tu-tu-tu-tu”, or “chink-chink-chink-chink-chink”, usually with 5–10 notes and lasting 1–1.25 seconds; like that of *S. rufifrons* but notes tend to be clearer, often sounding more spaced, and usually with more obvious pause (occasionally no pause) after first note. Introductory notes sometimes given singly. When alarmed, utters scolding “chrrrrr-rrr”, “chirrrrr” or “chrrrrr”.

**Habitat.** Broadleaf evergreen forest, bamboo stands, also dense bushes, *Rubus* thickets, deserted cultivation and clearings; also secondary forest, pine forest and upper montane primary vegetation in Sumatra. Found at 300–2600 m in Indian Subcontinent, 450–2600 m in SE Asia (but above 1065 m in Peninsular Malaysia) and China; 680–3000 m in Sumatra (“to highest peaks”). Habitat and altitudinal range very like those preferred by *S. ruficeps*.

**Food and Feeding.** Insects, including ants (Formicidae), caterpillars; occasionally berries. Forages in lower to middle storeys. Outside breeding season (from Aug) found in mixed flocks with Old World warblers (Sylviidae) and other species of babbler, often *Stachyris nigriceps*, or in family groups; sometimes in monospecific flocks.

**Breeding.** Jan–Jul. In Bhutan song heard as early as mid-Feb but mostly late Mar–Jul, with peak territorial activity later, in May–Jun. Nest a dome or ball with entrance near top, made of dry bamboo or other leaves and pine needles, lined with rootlets (or unlined), placed on ground among dead leaves, on bank, in bamboo clump or bush or suspended from pine branch in foliage, up to 0.6 m above ground. Clutch 3–4 eggs, white (may appear pink-tinged when fresh), rarely with faint reddish-brown spots. No other information.

**Movements.** Resident, apparently with some seasonal wandering; in NE India described as occasional migrant in Kaziranga National Park (Assam), although could be low-density resident in area. **Status and Conservation.** Not globally threatened. Rare and local in Nepal. In Bhutan fairly common; near Zhemgang recorded density of 3.4 territories/km of road at 1600–1900 m, making it one of the commonest birds in warm broadleaf forest in country; present in Thrumshingla National Park. Locally fairly common in NE India, where present in e.g. Buxa Tiger Reserve (West Bengal), Nameri National Park (Assam), and Namdapha National Park, Eaglenest Wildlife Sanctuary and Mouling National Park (all Arunachal Pradesh). Status in Bangladesh uncertain, but possibly rare or even extinct. Uncommon in Natumataung National Park, in Myanmar. Common in China, where recently found in Nonggang National Nature Reserve and Chunxiu Nature Reserve, in Guangxi. Generally common in SE Asian range. Common in Doi Inthanon National Park, in Thailand. Common in Dong Hua Sao National Biodiversity Conservation Area (NBCA), locally frequent in Nam Kading NBCA, and common in parts of Nakai-Nam Theun NBCA, in Laos. In Vietnam, present in Ba Be National Park and Na Hang Nature Reserve and common in Tam Dao National Park (all in N), and in six protected areas in the Annamese Lowlands Endemic Bird Area. Present in Gunung Leuser National Park, in Sumatra.

**Bibliography.** Ali & Ripley (1948, 1971), Allen *et al.* (1992), Banua & Sharma (1999), Betts (1956), Bingham (1903), Birand & Pawar (2004), Buij *et al.* (2006), Chasen & Hoogerwerf (1941), Cheng Tsosin (1987), Cheng Tsosin & Cheng Pao-tai (1969), Choudhury (2003), Davies-Beaman (1944), Davidson (1998), Deignan (1963), Delacour (1929), Delacour & Jansoulle (1931a), James *et al.* (2001), Engelbach (1932), Evans & Timmins (1998),

## 93. Black-chinned Babbler

### *Stachyridopsis pyrrhops*

**French:** Timalie à bec rouge **German:** Schwarzkinntimalie **Spanish:** Timalí Barbinegro  
**Other common names:** Red-billed Babbler

**Taxonomy.** *St[achyris]. pyrrhops* Blyth, 1844, Nepal.

Genus formerly merged with *Stachyris*. Monotypic.

**Distribution.** NE Pakistan (Murree Hills) E to E Nepal.

**Descriptive notes.** 10 cm; 8–12 g. Dull biscuit-coloured babbler with red eye and blackish half-mask and chin. Crown is buffy grey (looking creamy from front) with thin brown lines, shading on nape, upperparts, upperwing and tail to plain pale buff-grey; lores to bill base and chin black, supercilium, ear-coverts, submoustachial area, throat and underparts buffy ochre, slightly duller on flanks; iris red; upper mandible dark brown, lower mandible flesh-coloured; legs pale brownish-flesh. Sexes similar. Juvenile is slightly less richly coloured than adult, black areas greyer. Voice. Song a fast series of very short loud whistles, extremely like songs of *S. ruficeps* and *S. rufifrons* but faster and slightly higher, with shorter, less slurred or level notes, and seems to lack offset introductory note; also gives slower version. Calls include soft “chir”, harsh scolding “chirrrrrr” and “irr-wir-wee” or “irr-wir-wir-wee”.

**Habitat.** Forest edge, open and secondary forest with low undergrowth, light forest, scrub-jungle, lantana thickets, bamboo, small nullahs and hedgerows; at 245–2750 m.

**Food and Feeding.** Insects, occasionally berries. Found in parties of 8–10 individuals, often in association with other species, including other babblers, in mixed flocks. Usually forages close to or on ground; rarely ascends trees, to 3–4 m.

**Breeding.** Apr–Aug. Nest a fairly deep cup or loose dome, made of dry grasses, dead leaves, woody stalks and plant fibres, lined with fibres, fine grasses, pine needles and black hair (sometimes unlined), placed up to 1.5 m (usually less than 0.6 m) above ground in bush. Clutch 3–4 eggs, white, lightly speckled and spotted with reddish-brown, pinkish-red or brick red, rarely unmarked. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Frequent but very local in Pakistan. Fairly common in Nepal from W to EC area, rare farther E. Fairly common in India, where seen intermittently in Rajaji National Park (Uttar Pradesh), and fairly common on New Forest campus at Dehra Dun, common in Dehra Dun valley, and common in Corbett National Park (Uttaranchal Pradesh).

**Bibliography.** Ali & Ripley (1971), Gaston *et al.* (1994), Grimmett *et al.* (1998), Hume & Oates (1889), Inskipp & Inskipp (1991), Koelz (1954), Martens & Eck (1995), Mohan (1997), Pandey *et al.* (1994), Probsting (1964), Rasmussen & Anderton (2005), Singh (2000), Tymstra (1993).

## 94. Rufous-capped Babbler

### *Stachyridopsis ruficeps*

**French:** Timalie de Blyth **German:** Rotkopftimalie **Spanish:** Timalí Coronirrojo  
**Other common names:** Red-headed/Rufous-crowned Babbler

**Taxonomy.** *Stachyris ruficeps* Blyth, 1847, Darjeeling, India.

Genus formerly merged with *Stachyris*. Geographical variation slight; some races possibly not tenable. Individuals of this genus observed in C Laos may belong with nominate race of present species or with race *insuspecta* of *S. rufifrons*; further study required. Seven subspecies recognized.

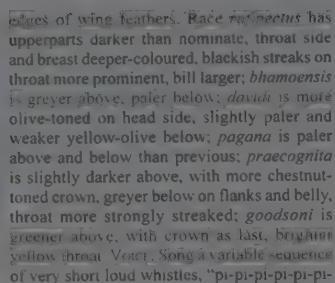

#### Subspecies and Distribution.

- S. r. ruficeps* (Blyth, 1847) – E Nepal E to NE India (E Arunachal Pradesh) and adjacent S China (SE Xizang).
- S. r. ruficeps* (Koelz, 1954) – E Arunachal Pradesh S to Nagaland, N Manipur and S Assam (N Cachar), in NE India.
- S. r. bharnensis* Harington, 1908 – NE Myanmar and S China (W & NW Yunnan).
- S. r. davidi* Oustalet, 1899 – C & SE China (S Shaanxi S to C Sichuan and S & E Yunnan, E to Zhejiang and Guangdong), NW Laos and N Vietnam (Tonkin).
- S. r. goodsoni* Rothschild, 1903 – Hainan I.
- S. r. praecognita* (Swinhoe, 1866) – Taiwan.
- S. r. pagana* Riley, 1940 – S Laos and S Vietnam (C & S Annam).

**Descriptive notes.** 12 cm; 7–12 g. Small, sharp-billed, pale olive and yellowish-buff babbler with rufous crown. Nominate race has crown and nape bright rufous, upperparts and neck side slightly greyish-olive, upperwing and tail a shade browner; face (lores, supercilium, ear-coverts) paler olive; yellowish-buff below, chin and throat with fine dark shaft streaks (sometimes invisible), lower belly, flanks and vent shading to buffy olive-brown; iris red or crimson, sometimes tinged rufous; bill blackish or brownish, lower mandible somewhat paler; legs greenish-brown to yellowish-grey. Sexes similar. Juvenile is rather less olive above than adult, crown paler, faint rufous

On following pages: 95. Rufous-fronted Babbler (*Stachyridopsis rufifrons*); 96. Visayan Miniature Babbler (*Micromacronus leytenensis*); 97. Mindanao Miniature Babbler (*Micromacronus sordidus*); 98. Pin-striped Tit-babbler (*Macronus gularis*); 99. Bold-striped Tit-babbler (*Macronus bornensis*); 100. Grey-cheeked Tit-babbler (*Macronus flavicollis*); 101. Grey-faced Tit-babbler (*Macronus kelleyi*); 102. Stripe-headed Tit-babbler (*Macronus striaticeps*); 103. Fluffy-backed Tit-babbler (*Macronus pilosus*); 104. Chestnut-capped Babbler (*Timalia pileata*).

**Bibliography.** Ali & Ripley (1948, 1971), Allen *et al.* (1997), Barua & Sharma (1999, 2005), Birand & Pawar (2004), Buij *et al.* (2006), Chasen (1939), Chasen & Hoogerwerf (1941), Choudhury (2003), Collar (2006), Cook (1913), Danielsen & Heegaard (1995), David-Beaulieu (1944), Davidson (1998), Deignan (1963), Delacour & Jabouille (1931a), Duckworth & Kersh (1988), Duckworth *et al.* (1997), Eames *et al.* (2001), Engelbach (1932), Garthwaite & Ticehurst (1937), Gönner (2006), Gore (1968), Grimmelt *et al.* (1998), Harrison (1984, 1987), Holmes (1996), Holmes & Burton (1987), Hopwood & Mackenzie (1917), Hume & Davison (1878), King *et al.* (2001), Koelz (1954), Lekagul & Round (1991), van Marle & Vooos (1988), Medway & Wells (1966), Nguyễn Duc Tu *et al.* (2001), O'Brien & Kinnaird (1999), Rasmussen & Anderson (2005), Robinson (1928), Robson (2000), Robson *et al.* (1998), Sharpe (1889), Sheldon *et al.* (2001), Singh (1995), Smith *et al.* (1940, 1943), Smythies (1986), Smythies & Davison (1999), Spierenburg (2005), Stanford & Mayr (1941), Stevens (1923), Stresmann & Heinrich (1940a), Thewlis *et al.* (1996), Thompson (1966), Ticehurst (1933), Tizard *et al.* (1997), Tordoff *et al.* (2002), Wilkinson, Dutton & Sheldon (1991), Wilkinson, Dutton, Sheldon, Darjono & Noor (1991).

**Subspecies and Distribution.**  
*S. r. ambigua* Harington, 1915 - N & E India (Sikkim and N West Bengal & throughout NE states; N Eastern Ghats in E Orissa and NE Andhra Pradesh), Bhutan, E Bangladesh, and NW Myanmar.  
*S. r. planicollis* (Mayr, 1941) - S part of N Myanmar; probably also W Yunnan, in S China.  
*S. r. pallescens* Titcherist, 1932 - W Myanmar.  
*S. r. rufifrons* (Hume, 1873) - SE Myanmar (including N Tenasserim) and NW & W Thailand.  
*S. r. adjuncta* (Deignan, 1939) - N Thailand, N & C Laos and N Vietnam (W Tonkin, N Annam).  
*S. r. obscura* (Stuart Baker, 1917) - S Thailand.  
*S. r. sumatrensis* (Hume, 1890) - Peninsular Malaysia, Sumatra and N & C Borneo.  
*S. r. borneensis* (J. basen, 1939) - W Borneo.

**French:** Timalie miniature **German:** Leyte-Laubsängertimalie **Spanish:** Timali Enano de Visayan  
**Other common names:** Leyte Tit-babbler, Miniature Babbler, Tit-babbler (when treated as conspecific with *M. sordidus*)

**Taxonomy.** *Micromacronus leytenis* Amadon, 1962, Dagami, 1500 feet [c. 460 m], Barrio of Patok, eastern shoulder of Mount Lobu, Leyte, Philippines. Formerly treated as conspecific with *M. sordidus*. Monotypic.  
**Distribution.** Samar, Biliran and Leyte, in EC Philippine Is.

**Descriptive notes.** 7–8 cm. Tiny babbler with bright yellow supercilium and underparts, and whitish spiny feathers projecting beyond tail from flanks and back. Male has crown and upperparts bright olive-green, crown feathers with indistinct black tips, lower back, rump and rear flanks with elongate, almost bare brown-tipped white shafts 4–4.5 cm in length; upperwing and tail dark brown with bright olive-green outer vanes; long supercilium from bill base bright yellow, lores, cheeks and ear-coverts olive-green, submoustachial area mottled olive on yellow; bright yellow below, thighs partly dusky; iris red; bill black; legs

greenish-grey, feet straw-yellow. Female is similar to male, but duller yellow. Juvenile apparently undescribed. **Voice.** No information.

**Habitat.** Undergrowth and canopy of montane broadleaf evergreen forest and forest edge; only published elevation 500 m.

**Food and Feeding.** Presumably small invertebrates; perhaps also small fruits. Found in small groups, often associating with other species, including white-eyes (*Zosterops*) and flowerpeckers (*Dicaeum*). Flock from which type series taken was feeding 15 m up on tall flowering tree; birds noisy and active, moving rapidly from branch to branch.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. When treated as conspecific with *M. sordidus*, listed as Data-deficient; formerly considered Vulnerable. Restricted-range species: present in Mindanao and the Eastern Visayas EBA. Records of this species are extremely few, and it is unclear what effect the widespread deforestation of its native islands have had on its populations.

**Bibliography.** Amadon (1962), Anon. (2006d), Butchart & Stattersfield (2004), Collar (2006), Collar *et al.* (2001), Dickinson *et al.* (1991), Kennedy *et al.* (2000), duPont (1971), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

## 97. Mindanao Miniature Babbler

### *Micromacronus sordidus*

**French:** Timalie de Mindanao

**Spanish:** Timali Enano de Mindanao

**German:** Mindanao-Laubsängertimalie

**Other common names:** Miniature Babbler/Tit-babbler (when treated as conspecific with *M. leytenis*)

**Taxonomy.** *Micromacronus leytenis sordidus* Ripley and Rabor, 1968, mountains of south Mindanao, Philippines.

Formerly treated as conspecific with *M. leytenis*. Monotypic.

**Distribution.** Mindanao, in S Philippine Is.

**Descriptive notes.** 7–8 cm; 5.5 g. Resembles *M. leytenis*, but slightly larger in size, with slenderer paler bill and shorter elongated back and flank plumes. Plumage much duller overall, without any bright yellow tones, being a shade duller and greyer above, pale yellowish-grey to greenish-olive below, with grey-green lores, rather pale in centre, dark olive supercilium concolorous with crown; iris and leg colours probably as in *M. leytenis*, bill horn-grey. Sexes similar. Juvenile is buffier above than adult, with warm cinnamon edges of wing feathers and shorter dorsal shafts, dull whitish below. **Voice.** No information.

**Habitat.** Undergrowth and canopy of montane broadleaf evergreen forest, at 600–1670 m.

**Food and Feeding.** Presumably small invertebrates; perhaps also small fruits. Seen to forage in canopy of montane forest with flock of Mountain Leaf-warblers (*Phylloscopus trivirgatus*).

**Breeding.** Males in breeding condition in May–Jun and recently fledged young in Jun. No other information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. When treated as conspecific with *M. leytenis*, listed as Data-deficient; formerly considered Vulnerable. Restricted-range species: present in Mindanao and the Eastern Visayas EBA. Recorded in Mount Apo and Mount Kitanglad National Parks; ecological requirements, however, so poorly known that it is unclear what effect deforestation in much of the species' lower range may have had on its ability to survive.

## Genus *MACRONUS* Jardine & Selby, 1835

## 98. Pin-striped Tit-babbler

### *Macronus gularis*

**French:** Timalie à gorge striée **German:** Strichelmeisentimalie **Spanish:** Timali Goliestriado

**Other common names:** Yellow-breasted Babbler/Tit-babbler, Striated/Striped/Stripe-throated Babbler/Tit-babbler

**Taxonomy.** *Timalia gularis* Horsfield, 1822, Sumatra.

Original description of genus included two different spellings of name (*Macronus*, *Macronous*); current name determined by ICZN Principle of First Reviser (see page 78). Formerly treated as conspecific with *M. bornensis*. Geographically isolated Philippine race *woodi* distinctive, and perhaps better treated as a separate species or, conceivably, as conspecific with *M. kelleyi*, with which (along with *M. flavicollis*) it shares song type. Many races weakly differentiated, and published diagnoses often based on trivial differences and not always supported by museum evidence; number of races probably too high, and several may in due course be synonymized. Fourteen subspecies currently recognized.

#### Subspecies and Distribution.

*M. g. rubicapilla* (Tickell, 1833) – Nepal, Bhutan, NE & EC India and Bangladesh.

*M. g. ticehursti* (Stresemann, 1940) – W & SW Myanmar.

*M. g. sulphureus* (Rippon, 1900) – N, E (except extreme E part) & SE Myanmar (including N Tenasserim), NW & W Thailand and S China (SW Yunnan).

*M. g. lutescens* (Delacour, 1926) – NE Myanmar, extreme NW & NE Thailand, S China (SE Yunnan, SW Guangxi), Laos and N Vietnam (Tonkin, N Annam).

*M. g. kinneari* (Delacour & Jabouille, 1924) – C Vietnam (C Annam).

*M. g. saraburiensis* Deignan, 1956 – EC Thailand and W Cambodia.

*M. g. versuricola* (Oberholser, 1922) – E Cambodia and S Vietnam (S Annam, Cochinchina).

*M. g. chondorensis* (Robinson, 1920) – Con Son I, off S Vietnam.

*M. g. connectens* (Kloss, 1918) – extreme S Myanmar (S Tenasserim) and adjacent SW, SC & SE Thailand.

*M. g. archipelagicus* (Oberholser, 1922) – Mergui Archipelago, off SW Tenasserim (Myanmar).

*M. g. inveteratus* (Oberholser, 1922) – coastal islands off SE Thailand and adjacent Cambodia.

*M. g. chersonesophilus* (Oberholser, 1922) – S Thailand and N Peninsular Malaysia.

*M. g. gularis* (Horsfield, 1822) – S Peninsular Malaysia S to Sumatra (including Banyak I and Batu Is).

*M. g. woodi* (Sharpe, 1877) – Palawan and Balabac, in W Philippine Is.

**Descriptive notes.** 11 cm; 10–14 g. Small, strong-billed babbler, brown above with chestnut crown, pale yellow below with narrow black breast streaks. Nominative race has crown dull chestnut, paler on nape, and slightly paler rufescent-brown upperparts, upperwing and tail; lores buffy, shading to grey-tinged pale yellow on supercilium and ear-coverts, these divided by narrow brownish eyestripe; chin, throat, submoustachial area and breast pale yellow with sparse long blackish shaft streaks, belly pale yellow, flanks, thighs and vent washed olive; iris yellowish-white to greyish-brown, orbital skin bluish-lead; bill slaty, lower

mandible paler; legs pale greyish-olive. Sexes similar. Juvenile is whiter below than adult, with weaker streaking. Race *connectens* differs from nominate in being slightly more olive above, with stronger yellow supercilium and slightly weaker breast streaks; *versuricola* is similar to previous but slightly larger, and darker above, more heavily streaked on lower underparts, with darker, greyer flanks; *inveteratus* is also similar but larger, paler and less rufescent above; *chondorensis* is also similar, but forecrown more chestnut, upperparts darker; *archipelagicus* is also larger, paler and more greyish above, paler on flanks; *chersonesophilus* is likewise larger, darker above, flanks darker, with broader streaks on throat (roughly intermediate between nominate and *chondorensis*); *rubicapilla* is much paler and more olive above than nominate, crown tinged rufous, wings and tail pale olive-brown, supercilium and ear-coverts pale yellow, breast streaks weaker; *ticehursti* is similar to last, but cap more rufous, underparts more extensively yellow; *sulphureus* is brighter yellow on face to breast, breast streaks finer; *lutescens* is brighter yellow still, with darker olive tinge on flanks, slightly darker cap, darker mantle; *kinneari* resembles previous but slightly more rufescent above, slightly bolder breast stripes; *saraburiensis* differs from *lutescens* in duller crown, paler mantle, from *sulphureus* in duller and darker crown and mantle, from both in having greyer wash on flanks; *woodi* is distinctive, differs from nominate in having crown chestnut-greyish, face greyish, mantle, back and scapulars dark greyish, underparts much paler, breast streaks almost absent.

**Voice.** Song varies somewhat. In N Vietnam repeated loud clear bouncing “ti chut-chutut-chut” or “tit-chutut-chutut-chutut...”, in C Annam and Thailand an even, well-spaced series of 4–5 notes. “chut-chut-chut-chut” (or with longer interval after first note), in Indian Subcontinent a loud, repetitive series of identical percussive notes, “chaunk-chaunk-chaunk-chaunk...”, reminiscent of a tailorbird (*Orthotomus*); Palawan race *woodi* has an even, monotonous, weak, flat series of 5–27 bell-like “chu” or “choh” notes, repeated every 1–2 seconds, with occasional odd notes given between full bouts. Typical calls include harsh “chrrt-chrrt”, “chrrt-chrr-chrrt” and “titiiti-chreeroo”; call of *woodi* a low grumbling “cht’tt’tt’tt’ut’ut’...”; scolding “tseep” given once per second when mobbing Asian Drongo-cuckoo (*Surniculus lugubris*).

**Habitat.** Bushes and undergrowth in open broadleaf evergreen, deciduous and semi-evergreen forest, bushes and scrub on forest edge, logged areas, bamboo, long grass and brushwood; also swamp-forest, plantations, gardens, coastal scrub; locally mangroves and associated transitional habitats, e.g. in S Bangladesh (Sundarbans). Occurs at up to 1000 m in Indian Subcontinent and China; usually only to 800 m in Bhutan, with one record at 1800 m; to 1525 m in SE Asia and Palawan.

**Food and Feeding.** Insects, including small beetles (Coleoptera), caterpillars, ants (Formicidae), grasshoppers (Orthoptera), also spiders (Araneae); also some fruit. Parties of up to twelve or more individuals; singly or in pairs during breeding season. Often in mixed company with other species, including other small babblers. Forages usually near ground but climbs vine-laden trees, often 6–9 m above ground; occasionally feeds on ground. Creeps and clambers about in a more unobtrusive manner than do many *Stachyris* and *Stachyridopsis* babblers.

**Breeding.** Feb–Jul generally; Dec–Aug in Peninsular Malaysia; nest and egg in Apr, dependent young in mid-Aug and mid-Oct, and nest-building in Sept in Sumatra; breeding-condition birds in Apr and May and nest in Jun in Philippines (Palawan). Nest, built by both sexes, a ball or rough dome, entrance at front or side (often near top), made of dead bamboo, bark strips or other leaves, grasses, palm strands, debris and plant fibres, sparsely lined with fine grasses, fine stalks, fine fibrous rootlets and fibres (or unlined), placed 0.3–3 m (sometimes to 4.6 m) above ground in bush, stemless palm, bamboo clump, hedge, pineapple plant, among ferns or other low vegetation, among mass of vines or mass of orchids hanging from tree, or on overgrown stump. Clutch 2–5 eggs (usually 3–4 in India and Myanmar, 2–3 in S regions and Palawan), white to dull white (sometimes with very faint pinkish tinge) with small blotches and specks of purplish-brown to yellowish-brown and/or brick-red. No information on incubation and nestling periods.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally common across range. Frequent from W to C Nepal, common E from C Nepal. Frequently recorded in foothills of Bhutan, most regularly in E above Samdrup Jongkha, with up to 35 recorded per day. Common in India: common

**Descriptive notes.** 14 cm. Crown is dull rufous, shading to slightly grey-tinged brown on mantle and to dull rufous-tinged brown on remaining upperside; upperwing and tail: face (lores, narrow short supercilium, ear-coverts and cheek) and neck side pale grey, submoustachial area pale grey (with vague narrow dark flecks); chin, throat and breast very pale yellowish with very narrow sparse blackish-narrow shaft streaks, remaining underparts plain grey-tinged pale yellow; iris pale yellow to amber; bill blackish; legs yellowish-brown. Distinguished from very similar *M. gularis* by having supercilium and head side grey, crown more uniform with upperparts, underparts paler and barely streaked. Sexes similar. Juvenile has greyer underparts with diffuse narrow dark throat streaks. Voice.—Song a soft, even, fairly well-spaced series of 2–20 notes (usually c. 8–12), "tuh-tuh-tuh-tuh-tuh-tuh-tuh". Calls include harsh "chrrrri-chrrruu-chrrrii-chru", "chrrree-chrrrr" and "chi-i-chrrrr", coarse "wi-ti-u-euu" and hoarse squeaky "trrrrt trrrtt...".

*T. p. pileata* Horstfield, 1821 - W Java.

**Descriptiv notes.** 15.5–17 cm; 15–23 g. Medium-sized babbler with rather long graduated tail, thick black bill, black half-mask, white face and breast and chestnut cap. Nominative race has forehead and supercilium whitish, crown chestnut, upperparts and upperwing pale olive-brown with rufescent tint, vague blackish streaks on mantle, tail greyer olive-brown with indistinct narrow brownish bars; lores to bill base and area immediately around eye, including narrow postocular eyestripe (separating supercilium from rest of face), black, ear-coverts whitish, neck side and breast side mid-grey; lower face, chin and upper throat

white, lower throat to breast white with fine black shaft streaks, belly pale creamy buff, flanks, thighs and vent dirty ochrous olive-brown; iris reddish-brown to crimson; bill black; legs dark brown, brownish-grey or brownish-olive. Sexes similar. Juvenile is warmer above than adult, with brown duller, no black streaks on breast, iris brownish-grey. Race *bengalensis* is darker above than nominate, only slightly rufescent, tail blackish-brown, belly pale olivaceous-buff; *smithi* is ep rufescent brown above and deep rufescent-buff on belly, both darker than any other race, tail rufescent dark brown; *intermedia* is rufescent-brown above, much paler than previous two, tail rufescent dark brown, belly rufescent buff; *patriciae* is pale olivaceous-brown above, tail dark brown, belly pale rufescent buff; *dictator* is pale rufescent brown above, tail rufescent dark brown, belly as last. Voice. Songs include sudden husky phrases ending with thin metallic notes, "wher-wher witch-it-it", "wher-er-itch-it-it" and similar, often by more than one bird at a time; also as "tseén-weer-krich-richrichit"; another version is loud musical whinny, evenly and rapidly descending, "tweér-r'r'r'r'r'r'r'r'r'r", fading and less musical near end. Calls include short, loud, stony, metallic "tizi" or "stik" notes, and harsh "chrrt" notes and varied low chuntering grumbles.

**Habitat.** Low-lying swampy areas, tall grass (including *Saccharum*), reedbeds, brushwood and scrub-jungle, often along streams and roads, also patches of *Eupatorium odoratum* and similar heavy cover in damp open areas, low bushes, thorn hedges and bamboo between cultivation; *Phoe-*

*nix paludosa* bushes in mangrove forest. At up to 1500 m in India, SE Asia and Java; 340–880 m in China.

**Food and Feeding.** Caterpillars, beetles (Coleoptera) and other insects and their eggs. Found in pairs during breeding season; otherwise in small parties of up to 6-8 individuals, often in association with *Chrysomma sinense*. Keeps low down in vegetation.

**Breeding.** Feb–Oct in India and Apr–Sept in SE Asia; probably multi-brooded. Nest, built by both sexes, described as a rough ball, oval or dome, with rather large entrance at side, or sometimes a deep cup, made of dry coarse grasses, straw, dry bamboo or other leaves and rootlets, scantily lined with fine grasses and rootlets (or unlined), placed up to 1 m above ground low down in bush or sapling, invariably surrounded by long grass, on spikes protruding from grass nodes, or on ground sheltered by bush or grass tussock. Clutch 2–5 eggs (usually 3–4 in India and Myanmar, 2–3 in Java), white (rarely pinkish), thickly speckled or finely blotched with various shades of brown and with little spots and clouds of pale ink-purple or dark ink-grey, in Java described also as pale grey with dark red speckles. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon in Nepal except in Royal Chitwan National Park, where common. Locally common in India, where common in Dudhwa National Park (Uttar Pradesh), Bhitarkanika Wildlife Sanctuary (Orissa) and Dibru-Saikhowa and Kaziranga National Parks (Assam), and present in Ngengpui Wildlife Sanctuary (Mizoram) and Buxa Tiger Reserve (West Bengal). Local in Bangladesh. Common in China, where recently found in Qinglongshan and Shiwandashan Nature Reserves, in Guangxi. Generally common in SE Asian range. In Laos, present but evidently uncommon in Xe Pian National Biodiversity Conservation Area (NBCA), Phou Xang He, Phou Xiang Thong and Dong Hua Sao NBCAs, but common in Phou Dendin NBCA. Uncommon in Cuc Phuong National Park, present in seven protected areas in the Annamese lowlands, and common in Nam Bai Cat Tien National Park, in Vietnam. Historically recorded from area of Gunung Gede-Pangrango National Park, and present in Ujung Kulon National Park, in W Java.

PLATE 9

PLATE 9

3 inches  
8 cm

## PLATE 9

## Family TIMALIIDAE (BABBLERS) SPECIES ACCOUNTS

### Genus *PTYRTICUS* Hartlaub, 1883

#### 105. Thrush-babbler

##### *Ptyrticus turdinus*

**French:** Akalat à dos roux **German:** Weißbauch-Drosseltimalie **Spanish:** Tordina Moteada  
**Other common names:** African Thrush-babbler, White-bellied Babbler, Jonjon

**Taxonomy.** *Ptyrticus turdinus* Hartlaub, 1883, Tomaya (4°38' N, 29°50' E), Sudan. Appears most closely related to genus *Illadopsis*. A pair of this species from E Central African Republic believed to belong in nominate race. Three subspecies recognized.

##### Subspecies and Distribution.

*P. t. harti* Grote, 1921 – C & E Cameroon.

*P. t. turdinus* Hartlaub, 1883 – extreme S Sudan, NE DR Congo; one record (probably this race) from E Central African Republic.

*P. t. upembae* Verheyen, 1951 – SE DR Congo, extreme E Angola and NW Zambia.

**Descriptive notes.** 16.5 cm; 59–73 g. Resembles large *Illadopsis* but song and underparts very different; rather long, straight and slightly hooked bill, powerful legs. Nominative race has forehead rufous centrally, whitish laterally, crown to mantle and neck side rufous, scapulars and back rufescent brown, uppertail-coverts bright rufous, tail brown with rufous fringes basally; lores, chin and throat white, cheek and ear-coverts mottled white and rufous, and small rufous teardrops at side of throat; breast white with rufous-brown triangular spots, belly to vent white, flanks white with rufous-brown marks; iris reddish to brownish-grey; upper mandible blackish with bluish-grey tip, lower mandible pale blue-grey; legs pale pinkish-grey. Sexes similar. Juvenile has brownish-black bill with yellowish-green lower base; rather deeper rufous above, especially on tail and outer webs of flight-feathers. Race *harti* is brighter rufous on tail than

babble. Low clucking calls, e.g. "chuck", given in agitation; loud cackling and chattering also reported.

**Habitat.** Dense bush and grass thickets along edge of forest streams, undergrowth in gallery forest, moist evergreen riparian forest, lowland damp woodland and thickets. To 900 m in Cameroon and NE DR Congo, and to 1600 m in SE DR Congo.

**Food and Feeding.** Invertebrates, including beetles (Coleoptera), grasshoppers (Orthoptera), caterpillars, cicadas (Cicadidae), small ants (Formicidae), termites (Isoptera), spiders (Araneae) and snails; also tiny frogs. Found in pairs or in small parties up to six individuals. Forages in undergrowth; strong legs suggest habitual terrestrial foraging, but only one such report to date.

**Breeding.** By inference, Jun–Nov in NE and Oct–Dec in S in DR Congo; birds in breeding condition in Feb in Angola; young juvenile in Oct in Zambia. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to locally fairly common in Cameroon, Central African Republic and Sudan; present in Upemba National Park, in DR Congo; uncommon in Angola. Does not occur in any protected area in Zambia, and all known sites for this species subject to worrying levels of deforestation.

**Bibliography.** Bannerman (1953), Benson (1958), Benson *et al.* (1971), Borrow & Deme (2001), Cave & Macdonald (1955), Chapin (1953), Fry *et al.* (2000), Hall & Moreau (1970), Lippens & Wille (1976), Louette (1981), Mitsch (1973), Nikolaus (1987), Oatley (1969).

## Genus *ILLADOPSIS* Heine, 1860

### 106. Black-capped Illadopsis

#### *Illadopsis cleaveri*

**French:** Akalat à tête noire **German:** Augenbrauen-Buschdrossling **Spanish:** Tordina Capirota  
**Other common names:** Blackcap Thrush-babbler/Akalat/Illadopsis

**Taxonomy.** *Drymocapthus cleaveri* Shelley, 1874, Fanti region, Ghana.

Formerly placed in genus *Trichastoma*. May form a superspecies with *I. albipectus*; occasionally treated as conspecific, but plumages distinctive and ranges parapatric. Individuals of this species in Ivory Coast and SE Guinea not yet assigned to race. Five subspecies recognized.

**Subspecies and Distribution.**

*I. c. johnsoni* (Büttikofer, 1889) – E Sierra Leone and W Liberia.

*I. c. cleaveri* (Shelley, 1874) – Ghana.

*I. c. marchanti* Serle, 1956 – SE Benin and S Nigeria.

*I. c. batesi* (Sharpe, 1901) – SE Nigeria (Obudu Plateau) and SW & S Cameroon E to SW Central African Republic, S to extreme W DR Congo.

*I. c. poensis* Bannerman, 1934 – Bioko I (Fernando Pó).

**Descriptive notes.** 15–16 cm; 22–36 g. Black cap and long pale eyebrow distinctive. Nominative race has crown blackish, hindneck grey, upperparts and head side bright rufous-brown, tail dark russet-brown; long, broad supercilium whitish-grey, cheek and ear-coverts blackish, neck side grey; chin to belly whitish, moustachial stripe greyish, breast side, flanks and undertail-coverts as upperparts; iris chestnut-brown; bill black; legs pinkish. Sexes similar. Juvenile is more rufous on breast and flanks, with dusky mottling below. Race *johnsoni* is darker than nominate, with less rufous upperparts, greyish wash on breast;

*poensis* is like previous but upperparts darker, with blackish barring on mantle and scapulars, darker breast side and flanks; *batesi* has slightly less blackish crown and ear-coverts, greyer supercilium, brownish breast wash; *marchanti* has dark olive-grey crown, less distinct (buffish) supercilium, brown-washed breast. **Voice.** Song, given all year (mainly in poor light at dawn, and in Gabon less intensively in long dry season Jun–Sept), consists of 1–2 resonant far-carrying whistles, usually introduced by 1–2 short quiet notes, "ptk whit whú whééé", very like that of *I. albipectus*; also a faster, rising series of 3 whistles introduced by 1–2 short notes, "whit whú-whéé-whifff", endlessly repeated. Alarm call "chk chk chk...", like that of *I. fulvescens* but louder; contact call a dry "prrr prrr...".

**Habitat.** Dense undergrowth and more open understorey of primary and mature secondary forest, *Raphia* swamp-forest, logged forest, forest-shrub mosaic, sometimes coffee groves; avoids pure stands of arrowroot (Marantaceae). Sea-level to 1500 m in Liberia (Mt Nimba) and Nigeria, to 1850 m in Cameroon (Mt Cameroon).

**Food and Feeding.** Invertebrates, including termites (Isoptera), small beetles (Coleoptera), crickets (Orthoptera), spiders (Araneae), millipedes (Diplopoda) and small snails. Forages on or near forest floor, rarely higher than 2 m; scratches in leaf litter and debris by fallen logs and tree bases,

inspects stems of broadleaved grasses and arrowroots. Found singly or in pairs, very rarely in larger parties, but sometimes joins bird waves and readily follows driver-ant columns.

**Breeding.** May–Nov in Liberia and Nigeria, Jan–Feb in Ivory Coast, all year in Cameroon, and Jan–Mar and Nov in Gabon; fledging in Feb on Bioko. Nest a large loose shallow cup, made of dead leaves with a few stems and rootlets, lined with *Murasmus* strands, placed on bed of leaves on ground, under bush covered with foliage or in low undergrowth, occasionally up to 0.6 m above ground. Clutch 2 eggs, white or pinkish-white with dull maroon and dark purplish-grey spots and markings or stronger reddish-brown markings; incubation by female only; no information on duration of incubation and nestling periods. Nests possibly parasitized by Red-chested Cuckoo (*Cuculus solitarius*). From seven clutches monitored, only one young fledged; one clutch was infertile, others probably preyed on.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally fairly common across range. Fairly common to common in Liberia, at coast and throughout forest zone; present in Tai Forest National Park, in Ivory Coast, and Bia and Kakum National Parks, in Ghana, being common in latter. Uncommon in S Nigeria. Present in Korup National Park and Lobeke Reserve, in Cameroon. Uncommon in Dzanga-Ndoki National Park, in Central African Republic; common in Gabon, where density 12–14 pairs/km<sup>2</sup>, and common in Odzala and Nouabalé-Ndoki National Parks, in PR Congo; last-mentioned, Dzanga-Ndoki and Lobeke form a continuous block.

**Bibliography.** Allport *et al.* (1996), Bannerman (1953), Borrow & Deme (2001), Brosset & Éard (1974, 1986), Chapin (1953), Colston & Curry-Lindahl (1986), David & Gosselin (2002b), Deme & Fishpool (1994), Dowsett-Lemaire (1997b), Dowsett-Lemaire & Dowsett (1991, 2000), Eisentraut (1973), Elgood *et al.* (1994), Fry *et al.* (2000), Gartshore *et al.* (1995), Gatter (1997), Grimes (1987), Hall & Moreau (1970), Louette (1981), Meise (1978), Rand *et al.* (1959), Rodewald *et al.* (1994), Serle (1954, 1957), Stuart (1986), Willis (1983).

### 107. Scaly-breasted Illadopsis

#### *Illadopsis albipectus*

**French:** Akalat à poitrine écaillée

**Spanish:** Tordina Pechiescamada

**German:** Schuppenbrust-Buschdrossling

**Other common names:** Scaly-breasted Thrush-babbler

**Taxonomy.** *Turdinus albipectus* Reichenow, 1887, Stanley Falls, DR Congo.

Formerly placed in genus *Malacocincla*. May form a superspecies with *I. cleaveri*; occasionally treated as conspecific, but plumages distinctive and ranges parapatric. Three subspecies recognized.

**Subspecies and Distribution.**

*I. a. barakae* (F. J. Jackson, 1906) – SE Central African Republic, NE DR Congo, extreme S Sudan, W & SW Uganda and W Kenya.

*I. a. albipectus* (Reichenow, 1887) – W & NC DR Congo.

*I. a. trensei* (Meise, 1978) – NW Angola.

**Descriptive notes.** 14 cm; 25–38 g. Nominative race has crown dark greyish-olive with darker scaling, upperparts, including upperwing, dark rufescent brown, tail dark brown; lores and cheek grey, latter with whitish mottling; narrow indistinct supercilium pale grey, ear-coverts olive-grey, becoming paler on neck side; chin and throat greyish-white, upper breast pale grey with vague olive tinge and sometimes vague dark scaling, lower breast and belly whitish, breast side, flanks and thighs olive-grey; iris brown to reddish-brown; upper mandible blackish, lower mandible pale grey; legs pale pinkish-grey. Distinguished from very

similar *I. rufipennis* by breast scaling (if present), less defined breastband, longer and paler legs, shorter rectral bristles, but mainly by voice. Sexes similar. Juvenile is more rufous above than adult, breast brownish, with rufous feathers above and around eye. Race *barakae* is browner on crown than nominate, paler grey on head side, narrower supercilium; *trensei* is paler and, on average, larger than other two. **Voice.** Song, throughout year, variable, apparently geographically. In Kakamega Forest (Kenya) and Kibale Forest (Uganda), consists of introductory "tip" and "tip" notes (sometimes soft "wheel" 2 seconds beforehand) and 2–3 (mainly 3) lively ringing high-pitched whistles, in ascending semi-tones, "tip tp-weeee-weeee-weeee", lasting 2–2.5 seconds, but some renditions may be protracted, e.g. "wheel... twir... wheel... twit... twittwee-tweee-tweeee" (7–8 seconds; last note longest and loudest, audible to 200 m); commonly repeated every 5–35 seconds (usually every 6–16 seconds) for more than an hour. Also as subdued chattering that breaks into 2–3 slowly delivered rising notes, "tiu tu ti". Foraging birds, possibly immatures, gave loud, liquid, high-pitched, drawn-out "peeeep-peeeep", repeated about five times at intervals of c. 30 seconds. "Pishing" caused immature to respond with "tittittittittit... see-u see-u see-u" (soft twittering followed by high whistles).

**Habitat.** Dense ground cover and areas with good leaf litter in lowland primary forest, seasonal swamp-forest and transitional forest, from valley bottoms to ridgetops, reaching 1525 m in Sudan, 2000 m in Uganda, 1700–2100 m in Kenya. In study in Uganda, treefall gaps found to be important as foraging centres and key to abundance of species, territory density increasing with increasing availability of such gaps, with highest densities in well-logged forest (although birds in such habitat experience dry-season stress as conditions drier than in unlogged forest).

**Food and Feeding.** Invertebrates, including ants (Formicidae), small beetles (Coleoptera), worker and soldier termites (Isoptera), other insects and their eggs, caterpillars, millipedes (Diplopoda) and small snails. Forages mostly on ground, occasionally up to 2 m; flips over leaves and scratches ground with feet. Found singly, in pairs or in family parties; sometimes found near bird waves, but does not join them.

**Breeding.** Bird in breeding condition in Jun in Central African Republic; breeds all year in DR Congo, Aug–Nov in Sudan, and Mar–Jul, Sept and Nov–Dec in Uganda. Only one nest described, a loose shallow cup of brown, damp, rotting leaves, lined with dead leaves and a few rootlets, sheltered on one side by a large fallen leaf, and well concealed on damp ground in slight depression under small fern; territory may be only 0.8–1.2 ha. Clutch 2 eggs, white with pale to dark brown blotches; no information on incubation and nestling periods. Recorded longevity in Kenya (Kakamega) at least 8 years 3 months.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common in SE Central African Republic; abundant in Congo Basin of C DR Congo; uncommon in Imatong Mts. in SE Sudan. Widespread and locally common, sometimes very common, in W & S Uganda; abundant in Kakamega Forest, in Kenya. Conservation status of isolated population in NW Angola unknown.

**Bibliography.** Borrow & Demei (2001), Britton (1980), Butyński (1989), Carswell *et al.* (2005), Cave & Macdonald (1955), Chapin (1953), David & Gosselin (2002b), Dean (2000), Fry *et al.* (2000), Hall & Moreau (1970), Lewis & Pomeroy (1989), Lindsell (2001a, 2001b), Mann (1985), Meise (1978), Nikolaus (1987), Stevenson & Fanshawe (2002), Traylor & Archer (1982), Williams & Arlott (1980), Zimmerman *et al.* (1996).

**108. Rufous-winged Illadopsis***Illadopsis rufescens*

**French:** Akalat à ailes rousses

**Spanish:** Tordina Alirufa

**German:** Rostschwingen-Buschdrossling

**Other common names:** Rufous-winged Akalat/Thrush-babbler

**Taxonomy.** *Turdiostris rufescens* Reichenow, 1878, Liberia.

Formerly often placed in genus *Trichastoma*. Monotypic.

**Distribution.** SW Senegal, SW Guinea, Sierra Leone, Liberia, S Ivory Coast, S Ghana and W Togo.

**Descriptive notes.** 16–17 cm; 32–41 g. Crown, upperparts and tail are rufous-brown, lores and head side paler brown, with vague buffy supercilium and whitish streaks on cheek; whitish below, pale brownish-grey tinge on breast and greyish flanks and vent; iris tawny-brown to dark brown; upper mandible black, lower mandible greyish or pinkish-horn with yellowish base; legs pale whitish-flesh. Distinguished from very similar *I. puveli* by greyer breast and flanks, lower mandible yellow only basally, but best separated by voice and habitat. Sexes similar. Juvenile apparently identical to adult.

**Voice.** Song, from high in trees (also from

ground), pleasant, simple, far-carrying and fast arrangement of 5–6 notes (several dry notes, a short whistle and 2 longer, louder, ringing whistles), “chk-chk-chk-hú-hú-hú” or “chit-chit-tu-hoo-hoo” or “tik tik tik pee pee-pee” (either all on one pitch or with first 3 notes higher), constantly repeated with only 1 second between deliveries. Alarm call a harsh, throaty “chk chk”, with rolling “churr” notes thrown in; also “whit-whit-whit”.

**Habitat.** Undergrowth in primary and old logged lowland broadleaf evergreen forest, often preferring rather open ground inside such forest, also dense high bush, sometimes disturbed farmbrush with forest remnants, forest edge, coastal thickets; rarely, plantations and logged forest. Found at 760–1220 m in Sierra Leone, and 535–1400 m in Liberia.

**Food and Feeding.** Beetles (Coleoptera), grasshoppers (Orthoptera), termites (Isoptera) and other insects; also small snails, and small amphibians. Forages close to or (mainly) on ground; turns over dead leaves, scratching them with feet, and hopping among ferns and other undergrowth. Found in pairs or family parties; sometimes joins bird waves.

**Breeding.** Bird in breeding condition in Apr and pair feeding young in Dec in Sierra Leone; food-carrying adult in Feb in Ivory Coast; breeding-condition birds all year, high song activity in Jun–Oct and newly independent juveniles in Nov–Jan in Liberia. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species; present in Upper Guinea Forests EBA. Generally uncommon to rare throughout range, and at risk from extensive destruction of forest; but can be common within good habitat. Only two records from Senegal, both in Basse Casamance National Park. In Sierra Leone, densities of calling birds in Gola Forest 2–6/6/km<sup>2</sup> in logged forest and 14–2–18–1/km<sup>2</sup> in primary forest; estimated total population in 1989 for Gola Forest North was 6392 individuals, and for Gola Forest East and West 3212. Locally common throughout forested parts of Liberia, reaching densities of 4–8 pairs/km<sup>2</sup>, and commonest illadopsis at Mt Nimba. In Ivory Coast, present in Taï Forest, Azagany and Marahoué National Parks and Nimba Nature Reserve. Fairly common in SW Ghana; rare in Togo, where only one confirmed record.

**Bibliography.** Allport (1991), Allport, Ausden, Fishpool *et al.* (1996), Allport, Ausden, Hayman *et al.* (1989), Anon. (2006d), Bannerman (1951, 1953), Barlow *et al.* (1997), Borrow & Demei (2001), Butchart & Stattersfield (2004), Cheke & Walsh (1996), Colston & Curry-Lindahl (1986), Demei (1995), Dickerman *et al.* (1994), Fry *et al.* (2000), Gartshore *et al.* (1995), Gatter (1997), Grimes (1987), Hall & Moreau (1970), Morel & Morel (1990), Serle (1949), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Thiollay (1985).

**109. Puvel’s Illadopsis***Illadopsis puveli*

**French:** Akalat de Puvel

**German:** Großfuß-Buschdrossling

**Spanish:** Tordina de Puvel

**Other common names:** Puvel’s Akalat/Thrush-babbler

**Taxonomy.** *Turdinus puveli* Salvadori, 1901, Rio Cacine, Guinea-Bissau.

Often placed in genus *Trichastoma*. Two subspecies recognized.

**Subspecies and Distribution.**

*I. p. puveli* (Salvadori, 1901) – SW Senegambia S to Guinea-Bissau, Guinea, N Sierra Leone, N Liberia and W Ivory Coast, and SE Ghana and S Togo.

*I. p. strenuipes* (Bannerman, 1920) – C & S Nigeria, Cameroon, extreme NE DR Congo and adjacent S Sudan and W Uganda.

**Descriptive notes.** 17–18 cm; 38–52 g. Nominative race has crown rufous-tinged brown with vague dark mottling, upperparts, including upperside, rufous-brown, tail darker; lores and head side brown with vague buffy supercilium and whitish streaks on cheek; whitish below, with warm peachy buff across breast, breast side brown, flanks and vent rufous-buff; iris brown; upper mandible black to blackish-brown, lower mandible yellow; legs whitish-flesh. Sexes similar. Juvenile is deeper rufous than adult, with more rufous-brown on breast. Race *strenuipes* is darker above than nominate, with tinge of olive, darker on breast and flanks, thighs brown. Voice, Song, for which male will ascend into trees, usually of 3–8 semi-musical notes in quick succession and repeated monotonously with short intervals, first 3–4 notes higher than last 2–4, which are louder but descend in pitch, “chip chip chip chee chee chee” or “pit-chip-per-chip-per-chip hur hee” or “wit ti-ti-tu-tu too”, higher-pitched and slightly more varied than that of *I. rufescens*; also as a musical series of

explosive, hollow, variably paced rising and falling notes, “tink-tink ching ching chi ching”, song in Uganda similar in structure, but chirped more than whistled. Female noted as giving repeated downslurred “peeeeee” in aggression, perhaps same as the loud “peey-aaar” (context unknown) heard in Uganda; contact or distress calls of trapped birds involved 3–4 rising and falling notes, to which a free adult responded with a churr.

**Habitat.** Undergrowth in lowland gallery forest, thick farmbrush, riverine and ravine thickets, second growth and secondary scrub, forest–grassland mosaic and savanna, reaching

primary ridge forest at 1400 m and secondary vegetation up to 1500 m on Mt Nimba (Liberia). At Zwedru, in Liberia, found in new farmland (3–7 years old) and *Harungana* scrub at the airfield; in Cameroon restricted to forest–savanna ecotone; in Budongo Forest, in Uganda, found in shrub understorey of *Rinoria ilicifolia* below dense-canopied *Cynometra*.

**Food and Feeding.** Invertebrates, including ants (Formicidae) and spiders (Araneae). Spends much of its time in foraging on ground in leaf litter or just above it, running from one spot to another, scratching among dry leaves and jumping from ground to glean items from leaves. Found singly or in pairs, sometimes in association with other species in bird waves.

**Breeding.** Nov in Ivory Coast and Mar in Sudan; breeding-condition bird in Aug in Liberia and in Nov in DR Congo. One nest was a mossy cup 2 m off ground in fork of small tree; another a loose cup made of dry leaves, pieces of bark and grass, woven into base of twigs in hollow scratched in ground, under fallen branch in opening in dense forest; held two nestlings. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally uncommon to locally common across range. Reported occurrence of nominate race in Mali now considered erroneous. Rare in Gambia and Senegal; fairly common in Liberia along N borders; one of the most widespread babblers in Ivory Coast, where common in Comoe National Park. Rare, but possibly overlooked, in Togo. Uncommon in forest zone in Nigeria; present in Korup National Park (N section) and Kimbe River Game Reserve, in Cameroon. Fairly common in Bengangai Forest, in SW Sudan; locally common in Budongo Forest, in Uganda.

**Bibliography.** Allport *et al.* (1996), Bannerman (1953), Barlow *et al.* (1997), Borrow & Demei (2001), Carswell *et al.* (2005), Chapin (1953), Cheke & Walsh (1996), Colston & Curry-Lindahl (1986), Dowsett-Lemaire & Dowsett (2005), Elgood *et al.* (1994), Fry *et al.* (2000), Gatter (1997), Grimes (1987), Hall & Moreau (1970), Louette (1981), Morel & Morel (1990), Nikolaus (1987), Owijunji (2000), Plumtre & Owijunji (1997), Salewski (1997), Serle (1957), Stevenson & Fanshawe (2002), Thiollay (1985), Traylor & Archer (1982), Wilkinson & Beccroft (1988).

**110. Pale-breasted Illadopsis***Illadopsis rufipennis*

**French:** Akalat à poitrine blanche

**Spanish:** Tordina Pechipálida

**German:** Grauungen-Buschdrossling

**Other common names:** Pale-breasted Thrush-babbler, White-breasted Akalat/Illadopsis

**Taxonomy.** *Trichastoma rufipennis* Sharpe, 1872, Gabon.

Was formerly often placed in genus *Malacocincla* or in *Trichastoma*. Has been thought to form a superspecies with *I. pyrrhoptera*, normally occurring at lower altitudes than latter in areas of sympatry in E of range. Race *distans*, differing from others in song and proportions, may represent a separate species. Birds from Pugu Hills (and Kazimzumbwi Forest Reserve), in Tanzania, sometimes separated as race *puguensis*, but considered better treated as part of *distans*. Four subspecies recognized.

**Subspecies and Distribution.**

*I. r. extrema* (Bates, 1930) – Sierra Leone E to Ghana.

*I. r. rufipennis* (Sharpe, 1872) – S Nigeria E to Uganda, W & SW Kenya and extreme NW Tanzania, S to NW Angola and C DR Congo.

*I. r. bocagei* (Salvadori, 1903) – Bioko I (Fernando Póo).

*I. r. distans* (Friedmann, 1928) – NE Tanzania, including Zanzibar.

**Descriptive notes.** 14–15 cm; 18–32 g. Nominative race has crown, lores, cheek, upperparts and tail dark rufous-brown (crown sometimes greyer in E of range), very slight pale eyering, head and face side slightly greyish and olive; throat white and distinctly bearded (puffed out in excitement), breast conspicuously pale buffish-brown with slight suffusion of greyish-olive at side, belly whiter; iris brown to pale brown; upper mandible blackish to blackish-brown, lower mandible pale horn to pale grey; legs bluish-grey to brownish-grey. Distinguished from very similar *I. fulvescens* mainly by smaller size, shorter tail, domed

(rather than flattish) crown, more contrast between upperside and underside. Sexes similar. Juvenile is richer brown on upperparts than adult, head without greyish tinge, browner on flanks and breast, and buffier on throat and belly. Race *extrema* is slightly smaller and more rufous-tinged, particularly on head, than nominate; *bocagei* has longer bill, deeper colour; *distans* is longer-tailed and larger-billed, with breast to belly pale grey, flanks more olive-brown. Voice, Song, singly or as duet or trio, all year in Gabon (less intensively in long dry season), very variable, rendered in different parts of range (although extent to which these geographically fixed is unclear) as a slow, meditative “twip tyooow weep”, “tyooow toowee toowee”, “chip heeheeewi”, “tyooow woy-whyee”, “hooon-hooonooe”, “weeeeee” and rising “peeeeee”, such notes often accompanied by other birds giving continuous low chatter, sometimes rising in volume and pitch, “tuk-tuk-tuk-wik-wik-wik-week-week-week...”, very like songs of *I. albipennis*, *I. cleaveri* and *I. fulvescens*, but more “pinched”, less clear, than that of last. In W Africa, at least, a second song type is a short ascending series of 2–3 pure whistles, introduced and accompanied by short notes, e.g. “whit tew wuuuu whééé”, repeated constantly. In E Tanzania (race *distans*) a rising and falling explosive nasal “tyah tyah”. Much churring conversation among flock-members, other calls include low nasal “tyank-tyank-tyank...” for contact when foraging, grating “ka-a-a” followed by throaty “kwo-kwo” in alarm, noisy “tizz”, and high insect-like “he, whooo” monotonously repeated.

**Habitat.** Dense undergrowth in primary and secondary humid broadleaf lowland, transition and montane evergreen forest, moss forest (on Bioko, at least), logged forest, forest patches in grassland mosaics, farmbush, coastal thickets, dense bush in clearings and along tracks, overgrown fields and plantations, often in wetter patches supporting large-leaved Marantaceae and Zingiberaceae. Generally at 500–1525 m, but 1000–2300 m in Kenya and 1220–1700 m in Tanzania.

**Food and Feeding.** Small invertebrates and their eggs, including moths and caterpillars (Lepidoptera), crickets (Orthoptera), beetles including elaterid larvae (Coleoptera), earwigs (Dermaptera), immature pentatomid bugs, ants (Formicidae), woodlice (Isopoda), centipedes (Chilopoda), spiders (Araneae) and small snails; nestlings provisioned with caterpillars and other larvae, and small crickets. Forages on or close to ground, below 5 m (usually below 0.3 m up, occasionally to 12 m), usually lower than *I. fulvescens*. Moves steadily through undergrowth, often in association with other species in bird waves, turning over leaves and debris in search of food; also on branches and trunks of trees and saplings, among lianas and Marantaceae, investigating leaf tangles and litter in epiphytes. Found singly, in pairs or in small parties (probably families) of 3–7 individuals. Observed with other species at driver-ant columns, and often in company of ribboned rope squirrel (*Funisciurus lemniscatus*).

**Breeding.** Oct–Feb in Sierra Leone, Jun–Jan in Liberia, Dec–May in Ghana, Dec–May and Jul–Aug in Cameroon, Jun–Mar (mainly Dec–Feb) in Gabon, almost all year in DRCongo, Mar in Sudan and Nov–Mar in Kenya and Tanzania; breeding-condition birds in Jan–Feb and immature in Jan in Uganda. Territorial. Possibly co-operative breeder: groups appear to defend areas against other groups. Nest of two different types, one a large loose deep cup resembling a leaf tangle, lined with rootlets, dead leaves and *Marasmius* fungal strands, placed 0.8–2.5 m up in leafiest part of isolated forest bush, the other a rudimentary flat cup made of rootlets, twigs and dry leaves with an outer layer of moss. Clutch 2 eggs, bright blue-green (in Gabon) to beige (in DRCongo) or greyish-white (E Tanzania), all with small reddish-brown or blackish-brown spots; incubation by female only, period 14 days; chicks fed by both adults and one or two immatures, nestling period 10 days; young provisioned by both parents and one or two immatures. Brood parasitism at one nest attributed to Olive Long-tailed Cuckoo (*Cercococcyx olivinus*).

**Movements.** Resident. Four ringed individuals recaptured at ringing sites 2, 7 and 14 months later; two individuals recaptured together at same site 12 months later.

**Status and Conservation.** Not globally threatened. Fairly common in Sierra Leone and SE Guinea. Although described as uncommon at Mt Nimba and in Yapo Forest, in Liberia, now regarded as common but overlooked from coast to N mountains. Common in Tai Forest National Park, in Ivory Coast; fairly common in Ghana, where present in Kakum National Park; fairly common in forest zone in Nigeria. One of commonest birds in Korup National Park, in Cameroon, and present in Lobeke Reserve; common in Gabon, where density reaches 12 pairs/km<sup>2</sup>, and present in Dzanga-Ndoki National Park, in Central African Republic; in PR Congo, common in Odzala and Nouabalé-Ndoki National Parks (last-mentioned forms continuous block with Dzanga-Ndoki and Lobeke). Rare in extreme S of Sudan. Present in various E African parks and reserves, including Kakamega (Kenya); in Tanzania, Pugu Hills population long thought to be close to extinction, while Udzungwa National Park holds up to 18 pairs/km<sup>2</sup>.

**Bibliography.** Bannerman (1951, 1953), Bannerman *et al.* (1986), Borrow & Demey (2001), Britton (1980), Brosset & Énard (1974, 1986), Carswell *et al.* (2005), Cave & Macdonald (1955), Chapin (1953), Colston & Curry-Lindahl (1986), David & Gosselin (2002b), Dean (2000), Dickerman *et al.* (1994), Dowsett-Lemaire & Dowsett (2000), Eisenraut (1973), Elgood *et al.* (1994), Field (1974), Fry *et al.* (2000), Gatter (1997), Grimes (1987), Hall & Moreau (1970), Jensen & Brøgger-Jensen (1992), Lewis & Pomeroy (1989), Mann (1985), Mlingwa *et al.* (1993), Moreau & Moreau (1937), Moyer (1993), Rand *et al.* (1959), Rodewald *et al.* (1994), Sclater & Moreau (1932), Serle (1950a, 1950b, 1954, 1957), Stevenson & Fanshawe (2002), Stuart (1986), Stuart & Hutton (1977), Stuart & van der Willigen (1978), van der Willigen & Lovett (1981), Zimmerman *et al.* (1996).

## 111. Brown Illadopsis

### *Illadopsis fulvescens*

**French:** Akalat brun **German:** Braunbauch-Buschdrossling **Spanish:** Tordina Parda  
**Other common names:** Brown Thrush-babbler, Brown-breasted Illadopsis; Moloney's Illadopsis (*moloneyana*, *iboensis*)

**Taxonomy.** *Turdiostris fulvescens* Cassin, 1859, Cama River, Gabon.

Has been placed in genus *Trichostoma* and in *Malacocincla*. Races *iboensis* and *moloneyana* have been thought possibly to represent a separate species; latter, however, appears to intergrade with race *gularis* in Ghana. Six subspecies recognized.

#### **Subspecies and Distribution.**

*I. f. gularis* Sharpe, 1870 – SW Senegal, Guinea-Bissau and Sierra Leone E to SW Ghana.

*I. f. moloneyana* (Sharpe, 1892) – SE Ghana E to SW Nigeria.

*I. f. iboensis* (E. J. O. Hartert, 1907) – SE Nigeria and SW Cameroon; also (probably this race) in C Nigeria (Jos Plateau).

*I. f. fulvescens* (Cassin, 1859) – S Cameroon S to S PR Congo, extreme W DRCongo, also W Central African Republic.

*I. f. ugandae* (van Someren, 1915) – SC Central African Republic and E PR Congo E through DRCongo to S Sudan, Uganda, W Kenya and W Tanzania, also NE Angola.

*I. f. dilutor* (C. M. N. White, 1953) – NW Angola.

crown, more rufescent above and below, than adult. Race *gularis* has head browner than nominate, little throat streaking, is more olive-brown below; *iboensis* is like previous above, chin to breast rufescent ochre with no streaking; *moloneyana* is rufous-brown above, rufescent brown below, with chin to breast rufescent ochre, legs blackish; *ugandae* is paler below than *gularis*, with throat purer white and virtually unstreaked (those from Bwamba, in W Uganda, considerably darker on crown, more olive on mantle, more olive-buff on breast and flanks, with more defined grey-tinged throat patch); *dilutor* is like last, but throat faintly streaked, breast brighter buff. Voice. Song,

usually a duet or trio, a slow, deliberate, simple pair of melancholy whistles (each variable in tone and pitch), a short upslurring “wheééé” or “tyop” and longer-drawn, ringing “whúúúú” or “waaah”, e.g. “tyop... waaah... tip... woou... tyop... waaah”, sometimes in 3-note version, lasting several seconds with intervals of 2–3 seconds; in Kenya and Gabon, singer accompanied by two or more others giving nasal “jip jip jappaaaangh” (“dict-a-phone” song), and in W Africa accompanists give rapid “gih-gih-ger-ger-ger...” chatter; in E Africa male described as having rhythmic descending “prrrrrp wiwi wiwi... wiyu”. Flock-members give little chattering, rolling and grating calls, “chip”, “chippa” “chrrr”, “chu-chu” and/or “jthree-jajajaja”; at driver-ant columns a short “chiii” and “cheu”; alarm calls include nasal “chwaa” and high, squeaky “weet weet weet” and “ek” notes.

**Habitat.** Dense undergrowth in clearings, thickets along roads, treefall light-gaps and vine tangles in primary forest and old secondary forest, transition forest, shrub-forest mosaic, farmbush, thick bush bordering forest, also sometimes tangled streamside vegetation in savanna country, gallery forest, coffee and tree plantations and logged forest, even in pure stands of arrowroot (Marantaceae). Evidently favours naturally disturbed patches, such as storm-damaged plots and streamside tangles where vegetation dense and complex cover extends laterally and vertically. In Upper Guinea forest commoner in logged and disturbed areas, whereas in Lower Guinea a species of primary forest. Apparently larger-billed and longer-tailed than its congeners, and adapted more for life in bushes. Generally lowlands to 1400 m, but to 1525 m in Sudan and Kenya, 1550 m in DRCongo and 1800 m in Uganda.

**Food and Feeding.** Mainly invertebrates, including small beetles (Coleoptera), bugs (Hemiptera), orthopterans (small grasshoppers, bush-crickets), termites (Isoptera), ants (Formicidae), moths and caterpillars (Lepidoptera), insect eggs, spiders (Araneae), centipedes (Chilopoda) up to 7 cm long, millipedes (Diplopoda) and small molluscs; also, a few hard brown seeds. Forages by pecking and probing, rather than sallying, habitually working its way up a liana tangle to c. 8 m, then flying down to next tangle, searching in leaf clusters, peering in dense debris, investigating dead wood, probing interlaced stems and dead leaves; commonly clings to vertical stems near ground. Occurs in pairs, in family groups or in small parties of 4–6 or so individuals, sometimes in association with other species in bird waves. When foraging with *I. rufipennis*, keeps higher in storey, at 10–16 m, and in dry season will move up into vine tangles in canopy; otherwise tends to stay in zone from on or near forest floor (0.5 m) to 18 m, mainly 4–12 m. Sometimes feeds in association with driver-ant columns, and often in company of ribboned rope squirrel (*Funisciurus lemniscatus*).

**Breeding.** Oct–Jun in Sierra Leone, Jun–Jan in Liberia, and juveniles in Oct and Dec in Ivory Coast; juveniles in Aug and breeding-condition bird in Oct in Nigeria; Sept–Nov, Feb–May and Jul in Cameroon, and Jul–Oct and Dec–Mar in Gabon; all year (or almost so) in DRCongo; Jun and Oct in Central African Republic; Aug in Sudan; nest with eggs in Jul, breeding-condition birds in Feb–May and Nov, and birds with brood patches in Oct and Dec in Uganda; Jun–Jul in Tanzania; breeding-condition bird in Sept in Angola. Territorial. Apparently in small groups consisting of mated pair and offspring from previous breeding season. Nest, constructed by both sexes, a large, loose, untidy shallow cup, sometimes with half-canopy, made of dead or decaying leaves, leaf skeletons, dead pieces of fern and fine stems, lined with tendrils, fine stems, rootlets, *Marasmius* strands and/or petioles, placed on ground, in sapling, low bush, small tree-fern or tangle of lianas, 0.5–2 m (exceptionally 3.5 m) above ground; may appear to be almost decaying from damp. Clutch 2 eggs, variably white, cream or pinkish-white, densely mottled maroon or reddish-brown. Sometimes with purplish-grey or pinkish-grey undermarkings (in Sierra Leone said to be pale greenish-blue, speckled brown or with heavy sepia blotches and smudges); incubation by only one member of pair (probably female), period at least 12 days; nestling period 14 days at one nest. Brood parasitism by *Chrysococcyx* cuckoos occurs. Of 12 nests in one study, 8 destroyed by predators and 4 fledged only four young.

#### **Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally common across range; numbers increase in logged forest (Liberia). Reports of this species' occurrence (race *gularis*) in Mali now considered erroneous. Regular in Basse-Casamance region of Senegal, so presumably in national park of that name. Common in Guinea, Sierra Leone and Liberia (where commonest illadopsis on Mt Nimba and Mt Wuteve at 1200–1400 m), and common in Yapo Forest, in Ivory Coast. Fairly common in the forest zone in Ghana, and more so in coastal thickets; fairly common in S Togo. Present in Korup National Park and Lobeke Reserve, in Cameroon; common to abundant at Mhini, in Gabon, where density reaches 10–12 pairs/km<sup>2</sup>; widespread and common in PR Congo from coast N to Brazzaville, and in Odzala and Nouabalé-Ndoki National Parks; in Central African Republic present in Dzanga-Ndoki National Park (this, Nouabalé-Ndoki and Lobeke forming continuous block). Commonest illadopsis in Congo Basin. Most widespread illadopsis in Uganda, and common in forests there. Rare in extreme S Sudan.

**Bibliography.** Allport *et al.* (1996), Bannerman (1953), Barlow *et al.* (1997), Borrow & Demey (2001), Britton (1980), Brosset & Énard (1974, 1986), Carswell *et al.* (2005), Cave & Macdonald (1955), Chapin (1953), Cheke & Walsh (1996), Colston & Curry-Lindahl (1986), David & Gosselin (2002a, 2002b), Dean (2000), Dowsett-Lemaire (1997a), Dowsett-Lemaire & Dowsett (2000, 2005), Eisenraut (1973), Elgood *et al.* (1994), Fry *et al.* (2000), Gatter (1997), Grimes (1987), Hall & Moreau (1970), Jackson & Sclater (1938), Lewis & Pomeroy (1989), Louette (1981), Morel & Morel (1990), Ngabo & Dranzoo (2001), Nikolaus (2001), Rand *et al.* (1959), Rodewald *et al.* (1994), Serle (1950a, 1950b, 1957, 1965), van Someren & van Someren (1949), Stevenson & Fanshawe (2002), Stuart (1986), Willis (1983), Zimmerman *et al.* (1996).

## 112. Mountain Illadopsis

### *Illadopsis pyrrhoptera*

**French:** Akalat montagnard **German:** Berghbuschdrossling **Spanish:** Tordina Montañesa  
**Other common names:** Mountain Thrush-babbler

**Taxonomy.** *Callene pyrrhoptera* Reichenow and Neumann, 1895, Mau (0°10' S, 35°41' E), Kenya. Previously placed in genus *Malacocincla*. Has been thought to form a superspecies with *I. rufipennis*, normally occurring at higher altitudes than latter in areas of sympatry. Two subspecies recognized.

#### **Subspecies and Distribution.**

*I. p. pyrrhoptera* (Reichenow & Neumann, 1895) – E DRCongo, SW & F Uganda, W Kenya, Rwanda, Burundi and W Tanzania.

*I. p. nyasae* (Benson, 1939) – N Malawi.

**Descriptive notes.** 13–14.5 cm; 20–30 g. Nominat race has olivaceous-grey crown with indistinct darker scaling, grey lores, cheek and neck side, narrow indistinct supercilium pale grey; upperparts dark rufous-tinged olive-brown, tail rufous-tinged brown; chin and throat greyish-white, shading to grey on breast and paler again on belly, latter tinged brown, flanks and undertail-coverts rich brown, thighs grey; iris hazel to reddish-brown, pale eyering; upper mandible greyish-black, lower mandible paler grey; legs brownish-grey to slate-grey. Sexes similar. Juvenile has whole upperside, including head, more rufescent-brown, crown like back. Race *nyasae* has top of head brown, breast paler grey than nominate. Voice. Song a duet, a simple melodious warble in which presumed male gives usually 3 well-spaced pure whistles on descending scale with interspersed brief chatter notes,

"whee... tata-whaaa... whoah" and "whee... tatata-whaaa... ta-whoah", while second bird (or several others) maintains unsynchronized chattering accompaniment, "chut-chut", "chipchipchip" and "prrrrr" (Uganda); song variable, perhaps geographically, but basic structure similar throughout range; also described as "trtrtrtr...ti-ti tiu tiyu", like that of *I. fulvescens* but higher and more rambling. Contact calls include continual low twittering "chek-chek" notes when on the move, and rolled, nasal "prreet".

**Habitat.** Bamboo and dense leafy undergrowth of primary and secondary montane and transi-

tion evergreen forest, gallery forest, impenetrable thickets 2–4 m high on slopes (e.g. with *Alchornea* and *Dracaena*) and along streams (e.g. with *Anisotes* and *Mimulopsis*); at 1550–2800 m in Kenya and Uganda, 1600–2300 m in Malawi.

**Food and Feeding.** Invertebrates, including ants (Formicidae), small crickets (Orthoptera), moths and caterpillars (Lepidoptera), and small snails; also berries and seeds. Forages in deep shade on forest floor and to 4 m up in vegetation, mostly below 1.5 m; turns over litter, probes leaf clusters,

hops through tangled fallen branches. Found in pairs and in small parties of 3–6 individuals; joins bird waves, and attends army-ant swarms.

**Breeding.** Jan–Feb and Jul–Aug, also breeding-condition bird and immature in May and bird with brood patch in Sept, in Uganda; breeding-condition bird in Mar in Kenya; Jun–Jul in DR Congo; oviduct eggs in Feb in Rwanda; breeds Sept in Malawi. Only one nest found, a substantial, rather sturdy cup of green moss, dry leaves, dry herb leaves and stems, thinly lined with dry rootlets and moss, 1.4 m above ground and extremely well hidden, as embedded 5 cm into dead dry leaves on thick bed of damp decaying leaves on rock ledge, overhung by fern leaves and dead tree leaves. Clutch 2 eggs, very pale blue-green with brown and purplish-brown splashes. No other information.

**Movements.** Resident; in W Kenya, irregular and rare occurrence in Kakamega Forest speculated as involving wanderers from higher areas (e.g. Nandi).

**Status and Conservation.** Not globally threatened. Generally uncommon to very common in different parts of range. Very common in W Rwanda. Often common in Uganda, and commonest at higher altitudes. Patchily common in N Malawi, where common in Uzumara Forest Reserve and fairly local in Nyika National Park, also in Chimaliro Army Range.

# Genus *PELLORNEUM* Swainson, 1832

## 113. Buff-breasted Babbler

### *Pellorneum tickelli*

**French:** Akalat de Tickell **German:** Rostbrust-Erdtimalie **Spanish:** Tordina de Tickell  
**Other common names:** Tickell's Babbler, Buff-breasted Jungle Babbler, Mountain Brown Babbler

**Taxonomy.** *Pellornium* [sic] *Tickelli* Blyth, 1859, "Woods of Teewap'hado", 1100 to 1500 feet [c. 35–460 m], Amherst District, Tenasserim, Myanmar. Formerly placed in genus *Trichostoma*. Has been thought possibly to form a superspecies with *P. pyrogenys*, presumably including *P. buettikoferi*. Previously considered conspecific with latter. Proposed race *garoense* (from Meghalaya and Manipur, and adjacent areas in NE India) may be worthy of recognition. Five subspecies currently recognized.

#### Subspecies and Distribution.

*P. t. assamense* (Sharpe, 1883) – NE India (Arunachal Pradesh, E & S Assam, Meghalaya, Manipur), E Bangladesh and N & W Myanmar.

*P. t. griseus* (Ticehurst, 1932) – SW Myanmar (W of R Irrawaddy).

*P. t. fulvum* (Walden, 1875) – S China (SW to SE Yunnan, W Guangxi), SE Myanmar, NW & N Thailand, N & C Laos and N Vietnam (Tonkin, N Annam).

*P. t. annamense* (Delacour, 1926) – N & E Cambodia, S Laos and C & S Vietnam (C & S Annam, Cochinchina).

*P. t. tickelli* Blyth, 1859 – S Myanmar (Tenasserim), W & S Thailand and Peninsular Malaysia.

dark horn-brown, lower mandible flesh-coloured; legs brownish-grey to yellowish-flesh. Sexes similar. Juvenile has strongly rufescent upperparts. Race *assamense* is darker above (darkest race), with darker ochre-buff underparts including some brownish feathering on breast side and flanks; *griseus* is paler and greyer above, much paler (cream-buff) below and on flanks; *fulvum* is slightly darker and colder above and on flanks; *annamense* is slightly warmer above, warmer buff below, with no white on belly. **Voice.** Song a loud, sharp, quickly repeated "wi-tee" or "wi-choo", sometimes incessantly repeated, without pause, e.g. "witweewitweewitwee..." or "witutitwitutitwitutit..."; also a high-pitched jolly laughing "swi-tit-tit-titchoo" and variants. Song in Indian Subcontinent transcribed as a loud, sweet, monotonous series of whistled, slightly slurred, upturned opposing couplets, "teet-sweéet, teet-sweéet..." Calls include harsh rattling "prree" or "trrit" notes, interspersed with higher "pieu" or explosive "whit" or "twit" notes, thus sometimes a sweet, sharply falling "(whit)-tseeuu".

**Habitat.** Evergreen forest and occasionally mixed deciduous open or deep forest, secondary growth, bamboo thickets, heavy cut-over scrub, undergrowth of edges of primary, logged and secondary forest. To 1550 m; above 610 m in Peninsular Malaysia.

**Food and Feeding.** Insects, including beetles (Coleoptera), and spiders (Araneae). Found in pairs; sometimes associates with other small babblers. Skulks in dense undergrowth; keeps close to ground.

**Breeding.** Mar–Jul generally; multi-brooded. Nest a domed, semi-domed or deep cup, made of dry bamboo or other leaves, fine grasses and thin blackish rootlets, scantily or neatly lined with fine grasses and roots, placed on ground, sometimes at base of sapling, or up to 1.5 m (usually less than 0.3 m) above ground in low bush or bamboo clump. Clutch 3–4 eggs, white to pale olive-grey, densely covered with dots, freckles and small blotches of reddish-brown to olive-brown, sometimes with underlying lavender and purplish-grey markings. No other information.

#### Movements.

Resident.

**Status and Conservation.** Not globally threatened. Locally common in India, where present in Namdapha National Park (Arunachal Pradesh). Locally common in Bangladesh. Common in limited range in China; recently recorded in Diding Nature Reserve (SW Guangxi), but at best uncommon there. Generally common in SE Asian range. Present in many protected areas in Thailand. Present (and often common) in Xe Pian National Biodiversity Conservation Area (NBCA) and in Hin Namno, Phou Dendin, Phou Khaokhoay, Phou Xang He, Xe Bang Nouan, Nakai-Nam Theun, Phou Xiang Thong and Dong Hua Sao NBCAs, in Laos. In Vietnam, common in Cuc Phuong National Park, and present in Na Hang, Thuong Da Nhim and Chu Yang Sin Nature Reserves, and in eleven protected areas in the Annamese lowlands.

**Bibliography.** Ali & Ripley (1948, 1971), Bangs (1921), Bingham (1903), Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paulai (1960, 1962), Choudhury (2003), Cox *et al.* (1992), David-Beaulieu (1939, 1944, 1950), Davidson (1998), Davidson *et al.* (1997), Deignan (1963), Delacour & Jabouille (1931a), Delacour *et al.* (1928), Duckworth (1998), Eames (1995), Eames *et al.* (2001), Engelbach (1932), Evans & Timmins (1998), Evans *et al.* (2000), Grimmett *et al.* (1998), Gyldenstolpe (1916), Hill (2000), Hopwood & Mackenzie (1917), Hume & Oates (1889), King & Han Lianxian (1991), Kinnear (1929), La Touche (1923), Lê Manh Hùng *et al.* (2002), Lê Xuân Canh *et al.* (1997), Lekagul & Round (1991), Mayr (1938), Medway & Wells (1976), Meyer de Schauensee (1984), Nguyễn Duc Tuat *et al.* (2001), Oates (1883), Rasmussen & Andersen (2005), Robbins *et al.* (2006), Robinson (1928), Robinson & Kloss (1919a), Robinson (2000), Round (1999), Showler, Davidson, Chanthavi Vongkhamheng & Khounmee Salivong (1998), Showler, Davidson, Khounmee Salivong & Khankhoun Khounholine (1998), Singh (1995), Smith *et al.* (1941), Smythes (1886), Stanfara (1935), Stanford & Ticehurst (1930), Ticehurst *et al.* (1996), Timmins & Trinh Viet Cuong (1999), Tizard *et al.* (1997), Waiston *et al.* (2001).

## 114. Sumatran Babbler

### *Pellorneum buettikoferi*

**French:** Akalat de Sumatra **German:** Sumatra-Erdtimalie **Spanish:** Tordina de Sumatra  
**Other common names:** Büttikofer's Babbler

**Taxonomy.** *Trichostoma buettikoferi* Vorderman, 1892, Lampung district, southern Sumatra. Previously treated as conspecific with *P. tickelli*; presumably part of possible superspecies formed by latter and *P. pyrogenys*. Monotypic.

#### Distribution.

Sumatra.

**Descriptive notes.** 15 cm. A nondescript babbler with disproportionately short tail, pale grey face. Crown, upperparts and side of neck olive-brown, tinged dull grey on crown and nape, with slight rufous tinge on upperwing and tail, pale feather shafts on crown forming narrow but fairly conspicuous streaking; lores, eyering and cheek pale buff with some olive-grey mottling or fine scaling, not sharply set-off from ear-coverts and stripe above eye, which are olive-grey with narrow pale shaft streaks; underparts, including underwing-coverts, isabelline-buff, grading to pale cream or off-white on throat and on mid-belly, and into

darker greyish-ochre on lower flanks and on outer thigh; upper breast marked with faint grey triangular marks; iris pale amber or red to pale brown; upper mandible grey, cutting edges and lower mandible horn-flesh; legs pale horn-flesh, sometimes pale yellow. Differs from very similar *P. tickelli* in paler plumage, shorter tail. Sexes similar. Juvenile is close to adult in colour, differing mainly in looser-webbed plumage, especially on belly to undertail-coverts; grey marks on breast vestigial or absent, lower flanks and undertail-coverts paler greyish-isabelline, mid-belly purer and more extensively white. **Voice.** Song a rather loud "pwiyu pii biyo" and "pii byo pwiyu", resembling that of *Trichostoma rostratum* but repeated more quickly and consisting of 3 whistles.

**Habitat.** Undergrowth in and edges of primary, lightly logged and heavily logged broadleaf evergreen forest, from coastal forest into hill forest to 900 m.

**Food and Feeding.** Insects, including beetles (Coleoptera) and caterpillars. Forages on ground; skulks in undergrowth.

**Breeding.** Mar–Jun, with dependent young in Aug and Dec. Clutch 2 eggs; young fed by both sexes. No other information.

#### Movements.

Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Conversion of lowland forest to oil-palm and other plantations extensive, especially since 1980s. Present in Gunung Leuser and Bukit Tigapuluh National Parks, in small numbers in latter.

**Bibliography.** Anon. (2006d), Buij *et al.* (2006), Butchart & Slatersfield (2004), Chasen & Hoogerwerf (1941), Danielsen & Heegaard (1995), Holmes (1996), Kloss (1931), MacKinnon (1988), MacKinnon & Phillips (1993), van Marle & Voous (1988), Meyer de Schauensee & Ripley (1940a), Ripley & Beeher (1985), Robinson & Kloss (1919b, 1920, 1924b), Stone (1903), Wells *et al.* (2001).

## 115. Temminck's Babbler

### *Pellorneum pyrogenys*

**French:** Akalat de Temminck **German:** Rostwangen-Erdtimalie **Spanish:** Tordina de Temminck

**Taxonomy.** *Myiothera pyrogenys* Temminck, 1827, Bantam Province, Java.

Has been thought possibly to form a superspecies with *P. tickelli*, presumably including *P. buettikoferi*. Proposed race *besuki* (from E Java) considered inseparable from nominate. Individuals of this species observed in N & S Borneo (E Sabah and S Kalimantan) apparently not assigned to race. Four subspecies recognized.

#### Subspecies and Distribution.

*P. p. canicapillus* (Sharpe, 1887) – N Borneo (W Sabah).

*P. p. longstaffi* (Harrison & Hartley, 1934) – NW Borneo (E & NE Sarawak and adjacent Kalimantan).

*P. p. erythrota* (Sharpe, 1883) – W Borneo (SW Sarawak and adjacent Kalimantan).

*P. p. pyrogenys* (Temminck, 1827) – Java.

**Descriptive notes.** 15 cm. Smallish babbler, dull brown above with darker cap, whitish below with rufescent breastband. Nominat race has crown greyish-brown with pale shaft streaks, upperparts rufous-brown, becoming slightly more chestnut on upperwing and tail, especially at base of latter; lores, cheek and ear-coverts rufescent brown with pale shaft streaks, submoustachial area to breast side and breast bright fulvous, chin and throat, belly and vent white (amount of rufescent brown apparently variable, may extend to flanks and vent); iris red-brown; bill black, lower mandible paler; legs brownish-flesh to lead-grey. Sexes

similar. Juvenile apparently undescribed. Race *erythrota* has upperparts paler than nominate, face side more rufous, breastband more distinct; *longstaffi* is larger, with blackish cap, deeper rufescent flanks and vent; *canicapillus* is like previous but smaller, breastband less extensive, cap blackish-grey. **Voice.** Song a quickly repeated, loud, rather shrill "witichew", with varying pauses between phrases; sometimes almost continuous, as e.g. "witichew witichew witichew", occasionally just "chew". Also has jolly, skipping ditty with slurred end-note, "tip'ip'ip'ip'ip-zrii".

On following pages: 116. Black-capped Babbler (*Pellorneum cupistratum*); 117. Puff-throated Babbler (*Pellorneum ruficeps*); 118. Brown-capped Babbler (*Pellorneum fuscicapillus*); 119. Marsh Babbler (*Pellorneum palustre*); 120. Spot-throated Babbler (*Pellorneum albiventris*); 121. Moustached Babbler (*Malacopteron mugnirostre*); 122. Sooty-capped Babbler (*Malacopteron affine*); 123. Sealy-crowned Babbler (*Malacopteron cinereum*); 124. Rufous-crowned Babbler (*Malacopteron magnum*); 125. Melodious Babbler (*Malacopteron palawanense*); 126. Grey-breasted Babbler (*Ophrydornis albobularis*); 127. Abbott's Babbler (*Malacocincla abbotti*); 128. Horsfield's Babbler (*Malacocincla sepiaria*); 129. Black-browed Babbler (*Malacocincla perspicillata*); 130. Short-tailed Babbler (*Malacocincla malaccensis*); 131. Ashy-crowned Babbler (*Malacocincla cinereiceps*).

**Habitat.** Undergrowth of primary forest, and dense vegetation at edges of clearings; lowlands to 1300 m in Java, 490–1550 m in Borneo, where considered a species of lower montane forest.

**Food and Feeding.** Ants (Formicidae) and large insects. Forages on ground, hopping (not walking), or keeps mainly to undergrowth below 3 m, sometimes working up vine-covered trees, picking items from plant stems near ground and undersides of leaves.

**Breeding.** Dec–Apr in Borneo. Nest a compact cup built in base of shrub, tussock or aerial root. Clutch 2 eggs, dull bluish-green, usually fairly thickly spotted with brown and purplish-grey or reddish. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common in Borneo; judged uncommon in Sabah, but fairly common in Mount Kinabalu National Park; present in Kayan Mentarang National Park, in E Kalimantan, and Gunung Niut Nature Reserve, in W Kalimantan. Present in Ujung Kulon National Park and scarce in Gunung Halimun National Park, in W Java, and in Alas Purwo National Park, in E Java.

**Bibliography.** David & Gussel (2003a), Davison (1997a), Grimham (2000), Holmes (1997), Hoogerwerf (1971), Kloss (1931), MacKinnon (1988), MacKinnon & Philipps (1993), Priem & Heegaard (1988), Ripley & Beeher (1985), Sheldon *et al.* (2001), Smythies & Davison (1999), Sody (1956), Thompson (1966), Wilkinson, Dutson & Sheldon (1991), Wilkinson, Dutson, Sheldon, Darjono & Noor (1991).

## 116. Black-capped Babbler

### *Pellorneum capistratum*

French: Akalat à calotte noire

Spanish: Tordina Coroninegra

German: Schwarzkappen-Erdtimalie

**Taxonomy.** *Myiothera capistrata* Temminck, 1823, Java.

Nominate race relatively distinct from others, and possibly a separate species; further study, including of vocalizations, required. Proposed race *nyctilampis* (from S Sumatra and Bangka) synonymized with *nigrocapitatum*. Four subspecies recognized.

**Subspecies and Distribution.**

*P. c. nigrocapitatum* (Eyton, 1839) – extreme S Myanmar (extreme S Tenasserim), S Thailand, Peninsular Malaysia, Sumatra, Bangka, Belitung and N Natuna Is.

*P. c. morrelli* Chasen & Kloss, 1929 – N Borneo (Sabah) and Banggi I.

*P. c. capistratoides* (Strickland, 1849) – W, C & S Borneo.

*P. c. capistratum* (Temminck, 1823) – Java.

**Descriptive notes.** 16–17 cm; 24–35 g. Brown-and-rufous babbler with striking head pattern. Nominate race has crown and nape black, supercilium from above lores to behind eye deep orange-rufous, becoming buffy white at rear, with grey eyestripe behind eye; lores pale buffy grey, ear-coverts pale orange-tinged buff with vague dark streaks; upperparts and underparts warm mid-brown, with vague olive cast on mantle, uppertail-coverts, tail and wing fringes tinged rufous; chin and centre of throat whitish, throat side and underparts rich rufous-tan or orange-rufous, flanks and undertail-coverts slightly darker or with some grey; iris brown to red; upper mandible black, lower mandible whitish to pale slate; legs pale brown or purplish-brown to dark blue-grey. Sexes similar. Juvenile has browner crown than adult, with orange-rufous also on throat. Race *nigrocapitatum* has supercilium and ear-coverts mid-grey with whitish shafts, rear ear-coverts mixed with orange-brown, well-marked blackish moustachial stripe, dark chestnut-brown upperparts, throat whitish, underparts deeper in tone than nominate, flanks and vent mixed with colour of upperparts; *morrelli* is like previous, but supercilium whitish with faint pale grey borders of feathers, ear-coverts overall darker grey, a little blacker on lores, faint narrow dark grey malar line, upperparts more chestnut; *capistratoides* resembles last, but with blacker ear-coverts, slightly darker upperparts and underparts. **VOICE.** Nominate race sings with loud, clear, full “ti-tuu” or “pi-tuu”, every 2–4 seconds, recalling second 2 notes of alternative song by race *morrelli*. Typical song of *morrelli* a thin, clear, mournful “ti-i-uu” or “ti-i-uu” repeated every few seconds (occasionally with simpler, flatter “tchu-i”), thus using 3 syllables; another song type in duet recalls that of *P. ruficeps*, presumed male uttering loud clear full “huu-ti-tuu” or “tuu-ti-tuu” (shorter gap between middle and last notes) every 5–10 seconds, presumed female giving whining nasal “weep-weep-weep-weep”. Race *nigrocapitatum* sings with loud, high-pitched “téeu”, repeated every few seconds. Calls include subdued “hekehkekheke...” and “yeryeryer...” and high nasal “nwit-nwit-nwit...”, also reported as liquid rising “pooee!”.

**Habitat.** Floor and understorey of primary broadleaved evergreen forest, logged and secondary forest, upland kerangas, peatswamp, bamboo and palm thickets, cane brakes, overgrown rubber, *Albizia*, cocoa, and sandy-soil scrub and forest adjacent to beaches and mangroves; to 760 m in SE Asia, but reaches 1300 m in Java and 1400 m in Borneo.

**Food and Feeding.** Insects, including orthopterans (grasshoppers, locusts), ants (Formicidae), termites (Isoptera), caterpillars and grubs; also spiders (Araneae), worms and snails. Found singly or in pairs. Forages on ground, usually with walking gait; runs along through leaf litter, takes short flights. Makes only short forays into undergrowth 0.5 m above ground.

**Breeding.** Apr–Jun in SE Asia, Feb–Apr and Aug–Dec in Java, and May–Jun in Kalimantan (Borneo). Nest described as an outwardly untidy cup, made of dead leaves, twigs, and coarse fern roots, lined with rootlets, fine fibres and fine dry grasses, placed on ground, sometimes in depression, sheltered by leaves, sapling or clump of ferns, or up to 0.6 m above ground in spiny palm or bush. Clutch 2 eggs, whitish or creamy, freckled with pale purplish-brown or maroon, with underlying pale pinky-purple to maroon spots and clouds. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally common in continental part of range, and common in N Borneo (Sabah). Numbers decline in response to fragmentation of lowland-forest habitat. Common in Khao Pra-Bang Kham Wildlife Sanctuary, in Thailand, and Taman Negara National Park, in Peninsular Malaysia. In Borneo, common in Danum Valley Conservation Area (Sabah), present in Similajau National Park (Sarawak), and common in Tanjung Puting National Park (S Kalimantan). Present in Gunung Leuser National Park and scarce in Way Kambas National Park, in Sumatra. Present in Ujung Kulon National Park, in W Java, and uncommon in Alas Purwo National Park, in E Java.

**Bibliography.** Buij *et al.* (2006), Chasen (1939), Chasen & Hoogerwerf (1941), Danielsen & Heegaard (1995), Deignan (1962), Duckworth *et al.* (1997), Grimham (2000), Hoogerwerf (1971), Hume & Davidson (1878), Jullien & Oates (1889), bin Jatan & Galdikas (1987), Johns (1989), Lambert & Collier (2002), Lekagui & Round (1991),

Löffing (2004), MacKinnon (1988), van Marle & Voous (1988), Medway & Wells (1976), Mees (1986), Nash & Nash (1988), Oates (1883), O’Brien & Kinnaird (1996), Parrott & Andrew (1996), Robinson (1928), Robson (2000), Sheldon *et al.* (2001), Smythies (1986), Smythies & Davison (1999), Sody (1956), Thompson (1966), Wilkinson, Dutson & Sheldon (1991), Wilkinson, Dutson, Sheldon, Darjono & Noor (1991).

## 117. Puff-throated Babbler

### *Pellorneum ruficeps*

French: Akalat à poitrine tachetée

Spanish: Tordina Pechiestriada

German: Streifenbrust-Erdtimalie

Other common names: Spotted/Striped Babbler

**Taxonomy.** *Pellorneum ruficeps* Swainson, 1832, Coonoor, Tamil Nadu, India.

Race present in N Myanmar uncertain, presumed to be *pectoralis*; similarly, in Cambodia, race in NE presumably *ubonense*, in E *deignani*, and in SE *dilloni*. Despite high number of named races, several more may exist, e.g. in Myanmar (Arakan, and in Sittang valley), in NC plains of Thailand, and in Peninsular Malaysia (Langkawi I). Twenty-eight subspecies recognized.

**Subspecies and Distribution.**

*P. r. punctatum* (Gould, 1838) – SW Jammu and Kashmir E to Uttaranchal Pradesh, in N India.

*P. r. mandellii* Blanford, 1871 – Nepal E to NE India (C Arunachal Pradesh).

*P. r. ruficeps* Swainson, 1832 – peninsular India except S.

*P. r. olivaceum* Jerdon, 1839 – SW India.

*P. r. pallidum* Abdulali, 1982 – SE India.

*P. r. chamelum* Deignan, 1947 – NE Indian states S of R Brahmaputra (except Manipur) and E Bangladesh.

*P. r. pectorale* Godwin-Austen, 1877 – NE India (E Arunachal Pradesh) and extreme N Myanmar.

*P. r. ripleyi* Deignan, 1947 – Margherita area of E Assam (NE India).

*P. r. vocale* Deignan, 1951 – Manipur Valley (NE India).

*P. r. stageri* Deignan, 1947 – S part of N Myanmar.

*P. r. hilarum* Deignan, 1947 – W (N Chin State) & C Myanmar.

*P. r. victoriae* Deignan, 1947 – C & S Chin State (W Myanmar).

*P. r. shanense* Deignan, 1947 – E Myanmar and S China (W & SW Yunnan).

*P. r. minus* Hume, 1873 – S Myanmar.

*P. r. subochraceum* Swinhoe, 1871 – SE Myanmar (including N Tenasserim) and adjacent W Thailand.

*P. r. insularum* Deignan, 1947 – extreme S Myanmar (S Tenasserim).

*P. r. indistinctum* Deignan, 1947 – extreme NW Thailand.

*P. r. chthonium* Deignan, 1947 – NW Thailand (except extreme N).

*P. r. elbeli* Deignan, 1956 – NE Thailand.

*P. r. dusiti* Dickinson & Chaiyaphun, 1970 – W slope of Dong Phrayayai range (W part of NE Thailand).

*P. r. acrum* Deignan, 1947 – W & S Thailand and N Peninsular Malaysia.

*P. r. oreum* Deignan, 1947 – S China (S Yunnan), N Laos and NW Vietnam (W Tonkin).

*P. r. vividum* La Touche, 1921 – SE Yunnan and N & C Vietnam (E Tonkin, N & C Annam).

*P. r. ubonense* Deignan, 1947 – NE (E part) Thailand, S Laos and adjacent NE Cambodia.

*P. r. euroam* Deignan, 1947 – SE Thailand and Cambodia (except E).

*P. r. deignani* Delacour, 1951 – S Vietnam (S Annam) and adjacent E Cambodia.

*P. r. dilloni* Delacour, 1951 – S Vietnam (Cochinchina) and adjacent SE Cambodia.

*P. r. smithi* Riley, 1924 – coastal islands off SE Thailand.

**Descriptive notes.** 15–17 cm; 21–31 g. Smallish babbler, pale brown above and buffy white below, with distinctive head pattern and broad streaks on breast and flanks. Nominate race has dull rufescent crown, nape and upper mantle, indistinct buffy tips of forehead feathers, buffy-whitish supercilium from bill base over buff-brown ear-coverts; upperparts warm-tinged pale greyish-brown, upperwing and tail browner with greyish-brown fringes; chin to lower belly buffy whitish, breast with prominent, broad pale grey-brown streaks that become broader and more suffused on flanks, vent lightly tinged buff with broad pale grey-brown centres; iris orange-brown to deep crimson; upper mandible greyish-brown, lower mandible fleshy yellow; legs yellowish-flesh or brownish-flesh. Sexes similar. Juvenile is paler than adult, with less contrast between crown and back, underparts dull white, washed with dull ashy ochre on sides, no lanceolate spots, undertail-coverts dull ashy ochre. Race *olivaceum* is larger than nominate, upperparts darker, crown dull chestnut, dark tips on forehead, border of ear-coverts darker, streaks on underparts heavier, darker and more oval, generally whiter below; *pallidum* is strikingly paler above; *punctatum* has greyish cast to forehead, and a hindcollar of streaked pale-edged darker feathers, underparts buffier; *mandellii* is like previous but wing and wing-coverts as nominate, crown darker and more chestnut than nominate, hindcollar much more boldly patterned, buffier below; *chamelum* is similar to last but paler and greyer above, streaks on underparts a little broader; *pectoralis* also is similar, but crown and nape darker, breast streaks more numerous and forming sharply demarcated gorget, streaks below broader overall, underparts a little richer buff; *ripleyi* also is similar, but crown richer-toned, more rufescent upperparts, richer buff wash below; *vocale* is like *chamelum* below, but crown more chestnut, darker above; *stageri* is darker than nominate, crown deeper-toned, upperparts darker, hindcollar strongly patterned, streaks below broader and more numerous; *shanense* differs from last in paler and brighter crown, weaker hindcollar, paler and more olivaceous upperparts, weaker and fewer breast streaks; *hilarum* is like previous, but hindcollar even less obvious; *victoriae* is like last, but crown paler and greyer, underparts paler; *minus* is like nominate in having no hindcollar pattern, but has brighter rufous crown than any of preceding races, with rufescent-tinged olive-brown upperparts, buff-washed underparts, sparse narrow breast streaks; *subochraceum* is like previous, but paler and more rufescent above, brighter buff below; *insularum* is similar to last, but darker and richer above and richer buff below, also warmer on ear-coverts and neck side; *acrum* also is similar, but darker and colder above, with deeper-toned crown, paler below; *chthonium* is like last above, but with weak hindcollar pattern, broader and more coarse breast streaks, whiter ventrally; *indistinctum* is similar to previous, but crown and upperparts vaguely paler, latter more rufescent, underparts slightly buffier; *elbeli* is darker above and more strongly streaked below than last; *dusiti* is like previous but much whiter below, with darker, narrower and more contrasting breast streaks; *oreum* is rather deep-toned above, has fairly well-defined hindcollar, weak buff wash below, fairly strong breast streaking; *vividum* is

like previous, but crown and upperparts vaguely paler, latter more rufescent, underparts slightly buffier; *elbeli* is darker above and more strongly streaked below than last; *dusiti* is like previous but much whiter below, with darker, narrower and more contrasting breast streaks; *oreum* is rather deep-toned above, has fairly well-defined hindcollar, weak buff wash below, fairly strong breast streaking; *vividum* is

like previous but crown darker, almost chestnut, upperparts deeper-toned (almost like *mandelli*), hindcollar still better defined, streaking below bolder; *euroum* is very similar to preceding race, but slightly darker and more rufescent above, hindcollar slightly weaker, warmer buff below; *deignani* also is similar, but breast streaks broader and more triangular, slightly greyer above; *ubonense* resembles *chthonium* but crown slightly darker, breast streaks broader and blacker; *dilloni* is like last but darker above, with relatively little contrast between crown and mantle, underparts strongly washed fulvous, breast streaks weaker and browner; *smithi* has crown and upperparts darkest of all races, underparts washed with dark rufescent buff. **VOICE.** Song a repeated loud, shrill, quite high-pitched “wi-chu” or “wi-ti-chu”, sometimes with more stressed end note; described also as persistently repeated whistle of 2–3 notes, with last note strongly downslurred. In peninsular India, gives 3-note call, second note highest, e.g. “pre-tee-déér”, sometimes with short prefix “tu-” or a more distinct 2-note “tui-déér”, with first note upslurred and second downslurred; in Himalayas, 2-note “preet-dééér” with first note higher than second. Also a jolly, rapid, descending sequence, “tuituitititit-tuititititit...”, and variants. Described also as a loud, sprightly “seet-seét’sit’sit-seét-seet-suut-suut-suut-suut-seét’sit’sit...”, second or third note in each phrase highest, subsequent ones hitching alternately down scale, with much lower one followed by a slightly higher one, so that phrase trends lower; phrases repeated several times without pauses before ending abruptly. Calls with subdued, nasal “chi” and “erh” notes and rasping “rrrrrrr”.

**Habitat.** Inhabits floor and understorey of deciduous or broadleaf evergreen forest, teak forest, secondary growth, bamboo, tea gardens, scrub, sholas, lantana thickets at forest edge, thickets in ravines and along watercourses, acacia, *Ziziphus*, etc.; occurs up to 1900 m (in Bhutan mainly below 1000 m).

**Food and Feeding.** Insects, including cockroaches (Blattodea). Found in pairs or small parties. Forages on ground, rummaging among and turning over dead leaves.

**Breeding.** Mar–Aug; multi-brooded. Nest described as a large, flimsy ball or dome, with entrance at side, or a semi-dome or cup, sheltered by large upward-pointing leaf (Tenasserim and S Thailand), made of dead bamboo or other leaves, grasses, moss, plant fibres and dead twigs, lined, often scantily, with fine grasses, fine stems of maidenhair fern, moss roots, fine roots, fibres and leaf stalks, placed on ground among dead leaves, at foot of bush or clump of grass or sheltered by stone. Clutch 2–5 eggs (usually 3–4 in N India, and 2–3 in S India, S Myanmar, S Thailand and Peninsular Malaysia), white, sometimes slightly tinged greyish, greenish, yellowish, buffish or cream, usually profusely (sometimes finely) speckled with bright reddish-brown or chocolate-brown to purplish-grey or lilac; no information on incubation period; distraction display noted during this stage of cycle; nesting period 12–13 days.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally common. Locally fairly common in C & E Nepal, rarer above 915 m. Frequently and regularly recorded in Bhutan. Generally common in India, where fairly common in Corbett National Park, on New Forest campus at Dehra Dun, and in Dehra Dun valley (Uttaranchal), seen intermittently in Rajaji National Park (Uttar Pradesh), common in Nameri and Kaziranga National Parks (Assam), and present elsewhere in NE India in (at least) Buxa Tiger Reserve (West Bengal), where 4.2 birds/km<sup>2</sup> in hill forest, also Barail Reserve Forest and Dibru-Saikhowa National Park (where common), in Assam, Eaglenest Wildlife Sanctuary (Arunachal Pradesh) and Dampa Tiger Reserve (Mizoram), and in Mudumalai National Park, in Tamil Nadu; in surveys in 1973–1997 in Western Ghats, found in 19 areas, including eight protected areas, namely Sultan’s Battery, Silent Valley, Parambikulam, Munmar, Periyar East, Periyar West, Tenmalai and Agastiamalai. Fairly common in China. Common in numerous protected areas in SE Asia. Common in Khao Pra-Kham and Kaeng Krachan National Parks, in Thailand. Fairly common and widespread, at least before 1970, in Cambodia. In Laos, common in Xe Pian National Biodiversity Conservation Area (NBCA), and in Xe Bang Nouan, Phou Xang He, Phou Xiang Thong and Dong Hua Sao NBCAs, and present in many other areas, including Nakai-Nam Theun NBCA. In Vietnam, present in Na Hang Nature Reserve (in N) and in nine protected areas in the Annamese lowlands, and common in Nam Bai Cat Tien National Park (Cochinchina).

## 118. Brown-capped Babbler

### *Pellorneum fuscicapillus*

**French:** Akalat à calotte brune **German:** Braunkappen-Erdtimalie **Spanish:** Tordina Coroniparda  
**Other common names:** Sri Lanka Babbler

**Taxonomy.** Dr[ymocotaphus], *fuscicapillus* Blyth, 1849, SW Sri Lanka.

Proposed race *scortillum* (SW wet-zone lowlands) falls within range of variation of nominate, and is therefore synonymized with it. Two subspecies recognized.

**Subspecies and Distribution.**

*P. f. babaulti* (T. Wells, 1919) – dry zone of N & E Sri Lanka.

*P. f. fuscicapillus* (Blyth, 1849) – wet zone of SW & C Sri Lanka.

**Descriptive notes.** 16 cm; 30 g. Smallish, plain brown babbler with dark brown crown and bright rufous-tan underparts. Nominata race has crown, nape and upper mantle dark brown with pale buff shafts, upperparts warm-tinged mid-brown with vague shaft streaks; upperwing and tail as upperparts, fringes of outer primaries paler and contrasting with darker primary coverts, tail tipped pale salmon-buff; head side and underparts bright rufous-tan, but ear-coverts slightly pinkish and throat pale pinkish-buff, breast side streaked with colour of upperparts; underparts variable, sometimes paler, particularly on mid-belly; iris red to red-brown; bill brown, paler lower mandible; legs pinkish-brown. Sexes similar. Juvenile apparently undescribed; unlikely to be very different from adult.

dergrowth both within and outside evergreen broadleaf forest, also overgrown land near villages, scrub and jungle; foothills to 1675 m.

**Food and Feeding.** Insects, including large beetles (Coleoptera). Found in pairs or in small parties of up to five or so individuals. Spends most time on or near ground, turning over dead leaves in search of insects.

**Breeding.** Feb–Apr and Sept–Dec, mainly Mar–Apr. Nest a loose ball with large lateral entrance, or occasionally a cup, made of dead leaves and moss, lined with dead leaves, and fine leaf and fern stalks, placed on ground among dead leaves, often at foot of large tree or cardamom clump, sometimes under tea bush, in brambles, in decayed tree hollow near ground, or in crevice in bank, up to 1 m above ground. Clutch 2–3 eggs, usually 2, white or whitish (exceptionally tinged buff or greyish-green), profusely speckled or with small blotches of brown, red-brown, purplish-brown or blackish-brown; incubation by both sexes. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Sri Lanka EBA. Common in lowlands and hills; widespread throughout the island, including Sinharaja Forest Reserve.

**Bibliography.** Ali & Ripley (1971), David & Gosselin (2002a), Grimmett *et al.* (1998), Harrison (1999), Henry (1998), Hoffmann (1984), Hume & Oates (1889), Kotagama & Fernando (1994), Legge (1880), Phillips (1978), Rasmussen & Anderton (2005), Stattersfield *et al.* (1998).

## 119. Marsh Babbler

### *Pellorneum palustre*

**French:** Akalat des marais **German:** Sumpf-Erdtimalie **Spanish:** Tordina Palustre  
**Other common names:** Marsh Spotted/Spotted Marsh Babbler

**Taxonomy.** *Pellorneum palustre* Gould, 1872, Cachar, Assam, India.

Monotypic.

**Distribution.** NE India (Brahmaputra floodplains in Assam and immediately adjacent Arunachal Pradesh) and NE Bangladesh.

heavy dark brown streaks of increasing length, breast side and flanks shading dark brown with rufous-buff tinge, belly white, lower flanks, thighs and vent dark ochrous-brown; iris brown to hazel; upper mandible deep brown to horn-brown, lower mandible pale brown to horn-brown; legs flesh-brown or pale bluish-brown. Sexes similar. Juvenile apparently undescribed. **VOICE.** Highly vocal. Song an electric crackling followed by rapid downscale whinnying, “kt’kt’ (‘wheeeeeeeeyu’), described also as varied, often starting with low throaty rolling “grgrgrgrgr chew hwee” or “grgrgrgrgr weehoo” or “chackchack chuhee”, each phrase repeated many times, followed sometimes by a series of “chichi chu-hee”. High-intensity calls include a strident upslurred note with dry clattering, “kd’d’d’tuwheék-kd’d’d’d’...”, an aggravated “chik-chik-tuwheéu”, a “kt’kt’kt’kwééuu”, with the last note clear, mechanical and rather bell-like, a frantic repeated “wheétkachewwheétkachew...”. Also gives short clattery bursts without intermingled clear notes.

**Habitat.** Reeds and coarse high grass bordering forest, swamps and rivers, elephant grass, savanna grassland, grass-jungle with trees, dense grass with *Veiveria zizanioides*, bushes, shrubs and low tree-jungle on marshy ground, damp forest scrub; lowlands to 800 m.

**Food and Feeding.** No information on diet; presumably small invertebrates and some vegetable matter. Very skulking; works its way through dense tall grass where large mammals have created tunnels, with “canopy” c. 1–1.5 m above ground.

**Breeding.** Feb–May. Nest reportedly ball-shaped, like that of *P. ruficeps*, made of grass, lined with finer grass or a few rootlets, placed on ground or among grasses and roots, always more or less covered by matted roots or fallen debris, inside tall grass and reeds. No other information.

**Movements.** Resident.

**Status and Conservation.** VULNERABLE. Restricted-range species: present in Assam Plains EBA. Scarce and very local; population probably declining rapidly in response to widespread loss of habitat. Known from 19 localities, 16 in India (three known to be occupied post-1980) and three in Bangladesh (one known to be occupied post-1980). Huge areas of grassland in N & NE India have been converted to farmland and plantations; moreover, seasonally flooded grassland has been affected by flood-control systems, remaining grassland areas are under great grazing and harvesting pressure, and grasslands are very poorly represented and poorly managed within protected areas. In India, species is present in Dibru-Saikhowa, Kaziranga, Manas and Nameri National Parks, also Eaglenest Wildlife Sanctuary; hard to assess density owing to reclusive behaviour, but regularly seen at these sites.

**Bibliography.** Ali & Ripley (1971), Allen (2002), Anon. (2006d), Barua & Sharma (1999), Butchart & Stattersfield (2004), Choudhury (2000, 2003, 2006), Collar *et al.* (2001), Grimmett *et al.* (1998), Rasmussen & Anderton (2005), Singh (1995), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stevens (1914), Thompson *et al.* (1993).

## 120. Spot-throated Babbler

### *Pellorneum albiventris*

**French:** Akalat à gorge tachetée **German:** Weißbauch-Erdtimalie **Spanish:** Tordina Golipinta  
**Other common names:** Brown/Plain Brown/White-bellied Babbler

**Taxonomy.** *Neornis albiventris* Godwin-Austen, 1877, Sengmai, Manipur, India.  
Four subspecies recognized.

#### Subspecies and Distribution

*P. a. ignotum* Hume, 1877 – SE Bhutan E to NE India (Arunachal Pradesh) and adjacent N Myanmar.  
*P. a. albiventris* (Godwin-Austen, 1877) – NE Indian hill states S of R Brahmaputra, also NE Bangladesh and W Myanmar.

*P. a. cinnamomeum* (Rippon, 1900) – E Myanmar, NW Thailand, S China (W & SW Yunnan), NW Laos and C & S Vietnam (C & S Annam).

*P. a. pusillum* (Delacour, 1927) – S China (SE Yunnan E to SW Guangxi) and N Vietnam (N Tonkin).

**Descriptive notes.** 14–15 cm; 21–22 g. Non-descript small round-tailed babbler, olive-brown above and below, with lightly stippled whitish throat and white mid-belly. Nominative race has crown, neck side and back olive-tinged mid-brown with very indistinct darker scaling, becoming slightly warmer on plain rear upperparts, upwearing and tail; face as upperparts but paler; chin, submoustachial area and throat greyish-white with greyish-buff flecks, breast ochreous-buff, shading to ochre-tinged olive-brown on breast side, flanks, thighs and vent; iris hazel to reddish-brown; upper mandible black or brown, lower mandible brighter; legs

brownish-flesh to purplish-horn. Sexes similar. Juvenile is warmer than adult, with rufescent edges of flight-feathers and greater wing-coverts. Race *ignotum* has greyish wash on lores and supercilium, greyish-brown pectoral band, dark of flanks more clear-cut from white belly, shorter tail, bill less well marked; *cinnamomeum* has more distinct dark chevron-like spots on throat, and paler rufous-buff underparts with little ventral white; *pusillum* has darker grey face, pale rufous base colour of chin and throat, darker and greyer flanks. Voice. Has surprisingly rich song like that of a thrush or chat (Turdidae), complex and quickly delivered but with much repetition: a long, loud relaxed series of simple mimicked phrases of clear short whistles and hard ringing notes, each phrase repeated a few times (often without a pause), sometimes with subdued guttural buzzy nasal notes. Presumed female may antiphonally interject a fast high metronomic downward-slicing “chiew-chiew-chiew...”. Calls include harsh angry buzzing “chrrr-chrrr-chrrr-chrrr...” and slightly explosive stony “tip” or “tchip” notes, quickly repeated.

**Habitat.** Scrub, secondary growth, bamboo, grassland, clearings, undergrowth in pine forest; from plains to 1830 m in Indian Subcontinent, 280–2135 m generally in SE Asia but 1100–2100 m in Thailand.

**Food and Feeding.** Insects. Shy and very skulking; in pairs near the ground in dense cover.

**Breeding.** Apr–Jul. Nest a small, compact globe or dome, sometimes semi-dome (or deep cup), made of grasses and bamboo leaves, lined with grasses and moss roots, placed in bamboo clump, bush, among tree roots or in grass or weed clump, on or 0.3–1.2 m above ground, sometimes a little higher. Clutch 2–5 eggs (usually 3–4 in India, and 3 in Myanmar), reddish-white or warm brick to pale cream or pale pink, profusely covered by speckles and tiny blotches of rather dark reddish-brown to pinkish-red; incubation by female; no information on duration of incubation and nesting periods. Occasional brood parasitism by Large Hawk-cuckoo (*Cuculus sparverioideus*) reported.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare in Bhutan, where known from five specimens, all from Deothang area in 1930s. Status in India uncertain, with few records; rare in Nameri National Park and uncommon in Dibru-Saikhowa National Parks (both Assam). Presumably a rare resident in Bangladesh, where one recent record. In China, rare in Yunnan; recently recorded in Guangxi in Shiwandashan National Nature Reserve and Diding Nature Reserve, but uncommon in both. Fairly common to common in SE Asian part of range. Fairly common in Doi Inthanon National Park and scarce in Doi Suthup-Pui National Park, in Thailand. Present in Dong Hua Sao and Nakai-Nam Theun National Biodiversity Conservation Areas, in Laos. In Vietnam, present in Thuong Da Nhim and Chu Yang Sin Nature Reserves and common all over Da Lat Plateau (S Annam), and in three protected areas in the Annamese lowlands.

**Bibliography.** Ali & Ripley (1971), Barua & Sharma (2005), Bingham (1903), Birand & Pawar (2004), Cheng Tsohsin (1987), David-Beaulieu (1944), Davidson (1998), Deignan (1963), Delacour & Jabouille (1931a), Delacour *et al.* (1928), Dickinson (1970), Eames (1995), Eames *et al.* (2001), Engelbach (1932), Grimmett *et al.* (1998), Harrington (1909, 1914a), Hopwood & Mackenzie (1917), Lekagul & Round (1991), Ludlow & Kinnear (1937, 1944), Rasmussen & Anderton (2005), Ripley (1949, 1952), Rippon (1901), Robbins *et al.* (2006), Robinson & Kloss (1919a), Robson (2000), Robson, Eames, Nguyễn Cu & Truong Van La (1993a), Robson, Eames, Wolstencroft *et al.* (1989), Showler, Davidson, Chanthavi Vongkhamheng & Khounmee Salivong (1998), Singh (1995), Smythies (1940, 1949), Spierenburg (2005), Stanford & Ticehurst (1938), Stevens (1914), Stresemann & Heinrich (1940a), Stuart Baker (1893), Thewlis *et al.* (1996), Thompson *et al.* (1993), Tizard *et al.* (1997).

sometimes with grey streaks, breast variably washed grey-brown and sometimes slightly streaked, remaining underparts silky whitish-buff; iris red to brown; upper mandible grey to black, lower mandible usually paler or blue-grey (bill much heavier than that of *M. affine*); legs grey or blue-grey. Sexes similar. Juvenile has moustache less distinct than adult, and uniformly flesh-coloured to yellowish lower mandible. Race *cinereocapilla* differs in having crown greyer, darker towards front, head side greyer and more clearly defined, breastband pale grey, and lower underparts silky greyish-white. Voice. Song a series of usually 3–6 well-spaced, clear, sweet whistled notes, “ti-tu-ti-tu” or “ti-tie-ti-ti-tu”, etc., usually lasting 2–3 seconds and sometimes descending somewhat towards end; female may give antiphonal harsh “tchew” or “tchip” notes. In N Borneo (Sabah) a short “doo-da-doo” followed by 4 descending notes, other sex giving counterpoint notes. Call a repeated soft but quite explosive “whit”, interspersed with buzzing “bzzi” notes.

**Habitat.** Primary broadleaf evergreen forest, peatswamp-forest, regenerating forests, heavily and selectively logged forests, upland heath, old rubber plantations and rarely *Albizia*. Occurs at up to 900 m in Thailand and Peninsular Malaysia, to 800 m in Sumatra; to upper margins of alluvial terraces to 915 m, rarely 1220 m, in Borneo.

**Food and Feeding.** Insects, including black beetles (Coleoptera) and locustids. Forages mostly in middle storey, at average height 4–6 m, but in depauperate kerangas forest may feed also from ground. Generally gleans foliage; can forage on vertical trunks, even upside-down, probing bark. Usually in small groups, sometimes associating with mixed flocks.

**Breeding.** Feb–Aug in SE Asia and Sumatra, Apr–May in Singapore; Oct–Jan (at least) and breeding-condition birds May in N Borneo (Sabah), with juveniles in May–Jun in Kalimantan. Nest an open cup, 1 m off ground in sapling; 2 eggs. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common in most of range. Rare in Singapore. Locally fairly common in Borneo and Sumatra, but common in Sabah. Present in Khao Pra-Bang Kham Wildlife Sanctuary, in Thailand, Taman Negara National Park, in Peninsular Malaysia, and Gunung Leuser, Bukit Tigapuluh and Way Kambas National Parks (scarce), in Sumatra. In Borneo, present in Danum Ulu Conservation Area, in Sabah, Similajau National Park, in Sarawak, and Tanjung Puting National Park (uncommon), in S Kalimantan.

**Bibliography.** Buij *et al.* (2006), Chasen & Hoogerwerf (1941), Danielsen & Heegaard (1995), David & Gosselin (2002a), Deignan (1963), Duckworth *et al.* (1997), Holmes (1996), Hume & Davison (1878), Johns (1989), Lambrecht (1992), Lekagul & Round (1991), van Marle & Voous (1988), Medway & Wells (1976), Nash & Nash (1988), O’Brien & Kinnaird (1996), Parrott & Andrew (1996), Rajithurai (1996), Robinson (2002), Robson (2000), Sheldon *et al.* (2001), Smythies (1986), Smythies & Davison (1999), Thompson (1966), Voous (1950), Wilkinson, Dutson & Sheldon (1991), Wilkinson, Dutson, Sheldon, Darjono & Noor (1991).

## 122. Sooty-capped Babbler

### *Malacopteron affine*

**French:** Akalat affin **German:** Schwarzscheitel-Zweigimalie **Spanish:** Tordina Coronioscura  
**Other common names:** Sooty-headed/Plain Babbler, Small Tree-babbler

**Taxonomy.** *Tr[ichastoma]. affine* Blyth, 1842, Singapore.

Has often been treated as monotypic, but race *phoeniceum* appears sufficiently distinctive to warrant recognition. Birds from Banyak Is (off W Sumatra) separated as race *notatum* on basis of size difference, but this was later shown to be non-existent. Two subspecies recognized.

#### Subspecies and Distribution

*M. a. affine* (Blyth, 1842) – S Thailand, Peninsular Malaysia and Sumatra (including Banyak Is, off W coast).

*M. a. phoeniceum* Deignan, 1950 – Borneo.

**Descriptive notes.** 15.5–17 cm; 14–21 g. Rather dark-backed hook-billed babbler with contrasting whitish underside, vague grey breastband, and dull chestnut tail. Nominative race has crown blackish-brown, upperparts darkish olive-brown, shading paler and more rufescent on rump; upwearing plain darkish brown, tail dull chestnut, richest at base; lores, supercilium and ear-coverts rather pale grey, becoming whiter on lower face, with submoustachial area white with vague grey stippling; chin and throat silky white, lower throat and upper breast with vague grey streaks, breast washed grey, shading back to silky whitish on lower underparts; iris red,

brown or chestnut; upper mandible dark horn to slate, lower mandible usually paler; legs grey to bluish-slate. Sexes similar. Juvenile has lower mandible pale, foreneck unstreaked, crown paler, browner and almost concolorous with rufescent-tinged mantle, wing feathers edged rufous, tail brighter. Race *phoeniceum* has brown cap. Voice. Song of two types. First a series of usually 6–9 clear, slow, airy, rising and falling whistles, in variable combination but usually spaced as (e.g.) 2, 3 and 3, “phu-phi, phu-phoo-phi, phi-phi-phi”, usually lasting 4–7 seconds; second (characterized as “errand-boy” whistling) a variable, cheerful and clearer version of first, usually in two 3-note phrases, “whi-whi-whi”, sometimes a faster “chut-whi-whi-whi-whi-whi-whi-whi”, sometimes introduced by short scratchy or jumbled notes. Calls include short, sharp “whit” or “pi-nwit” (sometimes used by female to accompany primary song of male), and harsh scolding rattles when alarmed.

**Habitat.** Fades and naturally disturbed areas of primary broadleaf evergreen forest, e.g. along rivers or tracks, peatswamp-forest, selectively logged forest, favouring secondary growth and forest edge, *Albizia*, overgrown rubber and oil palm (*Elaeis*); on Mt Mulu, in Borneo, present in riparian habitat only. Level lowlands in Thailand; to 455 m in SE Asia; up to 700 m in Sumatra.

## Genus MALACOPTERON Eyton, 1839

## 121. Moustached Babbler

### *Malacopteron magnirostre*

**French:** Akalat moustachu **German:** Bartstreif-Zweigimalie **Spanish:** Tordina Bigotuda  
**Other common names:** Brown-headed Babbler/Tree-babbler

**Taxonomy.** *Alcippe magnirostris* F. Moore, 1854, Malacca, Peninsular Malaysia.

Proposed race *flavum* (from Anambas Is) merged with nominate. Two subspecies recognized.

#### Subspecies and Distribution

*M. m. magnirostre* (F. Moore, 1854) – extreme S Myanmar, W & S Thailand, Peninsular Malaysia (including Tioman Is, Anambas Is, Singapore and Sumatra).

*M. m. cinereocapilla* (Salvadori, 1888) – Borneo.

**Food and Feeding.** Ants (Formicidae), beetles (Coleoptera) and caterpillars. Average foraging height 6–5 m. Gleans from foliage. Often in small parties in smaller trees and bushes, often in liana tangles.

**Breeding.** Apr–May in SE Asia; in Borneo, nest-building in Oct in Brunei, breeding in Jun–Oct and Jan in Sabah, and juveniles May–Jun in Kalimantan. Nest a loose shallow cup, made of dead leaves, twigs and fibres stripped from tree trunk, placed in triangle formed by stems of two saplings and creeper or among dead leaves attached to hanging dead twigs, 1–7 m above ground. Clutch 2 eggs, pink, with numerous pin-spots and blotches of reddish-brown over occasional clouds of lilac, with dense cap of deep red-brown and purplish-brown. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Rare to locally common in continental part of range; common in Taman Negara National Park, in Peninsular Malaysia. Common throughout lowland mixed dipterocarp forests in Borneo, and common in Sabah, including Danum Valley Conservation Area; frequent in Berau district forest, in E Kalimantan; present in Similajau National Park (Sarawak), and uncommon in Tanjung Puting National Park (S Kalimantan). In Sumatra, present in Gunung Leuser and Way Kambas National Parks, common in latter; recorded as common in the now destroyed Padang-Sugihan Wildlife Reserve, in S Sumatra. A Sundaic lowland-forest species, thus highly susceptible to the extensive forest destruction throughout its range; ability to survive in forest edge and secondary formations, however, implies that it is not immediately at risk.

**Bibliography.** Anon. (2006d), Buij *et al.* (2006), Butchart & Stattersfield (2004), Chasen (1939), Chasen & Hoogerwerf (1941), Collar *et al.* (2001), Danielsen & Heegaard (1995), Deignan (1963), Duckworth *et al.* (1997), Eames (2005), Johns (1989), Lambert (1992), Lekagul & Round (1991), van Marle & Voous (1988), Medway & Wells (1976), Mees (1986), Nash, S.V. & Nash (1985a, 1988), O'Brien & Kinnaird (1996), Parrott & Andrew (1996), Robson (2000), Sheldon *et al.* (2001), Smythies & Davison (1999), Stattersfield & Capper (2000), Voous (1950), Wilkinson, Dutson & Sheldon (1991), Wilkinson, Dutson, Darjono & Noor (1991).

## 123. Scaly-crowned Babbler

### *Malacopteron cinereum*

**French:** Akalat à calotte maillée

**Spanish:** Tordina Coroniescamada

**German:** Rotstirn-Zweigimalie

**Other common names:** Smaller/Lesser Red-headed Babbler/Tree-babbler

**Taxonomy.** *Malacopteron cinereus* [sic] Eyton, 1839, Peninsular Malaysia.

**Proposed race bungeense** (from N Natuna Is) merged with nominate. Four subspecies recognized.

**Subspecies and Distribution.** *M. c. indochinense* (Robinson & Kloss, 1921) – E Thailand, Cambodia, C & S Laos and Vietnam (S from SE Tonkin).

*M. c. cinereum* Eyton, 1839 – S Thailand, Peninsular Malaysia, Sumatra (including islands off E coast), N Natuna Is and Borneo.

*M. c. niasense* (Riley, 1937) – Nias I, off W Sumatra.

*M. c. rufifrons* Cabanis, 1851 – coastal S Java.

**Descriptive notes.** 14–16 cm; 14–21 g. Rather similar to *M. affine*, but paler above, with black-tipped dull rufous anterior crown, pale legs. Nominative race has erectile rufous crown feathers tipped with black (difficult to discern in field), blackish hindcrown and nape; upperparts and upperwing olive-brown, tail dull rufescent, strongest at base; lores, supercilium and area around eye pale brown with tiny white spotting, cheek and ear-coverts greyish-brown with buffy-white shaft streaks, submoustachial area buffy white with vague greyish flecks; chin to vent whitish, shadow of greyish breastband, flanks more buff-grey;

iris crimson to brownish-grey; upper mandible greyish-horn to black, lower mandible often paler; legs grey or flesh, even whitish. Sexes similar. Juvenile is similar to adult. Race *indochinense* has hindcrown and nape concolorous with upperparts; *rufifrons* is very like previous, but rufous extends onto hindcrown and has much smaller black tips, outer fringes of flight-feathers rufescent; *niasense* is like nominate but darker and larger, with larger bill. **VOICE.** Song variable, with four main parts which can be combined in various ways: first part a rapidly repeated, hard, stressed “dit-dit-dit-dit-dit-...” or “du-du-dit-dit-dit-...”; second a rapid, usually gradually descending “du-du-du-du-du-...”; third a more spaced, gradually ascending “phu-phu-phu-phu” and “phu-pu-pi-pee”; and fourth a rapid, high-pitched, even “wi-wi-wi-wi-wi-wi-wu”, “wi-wi-dududududu” or similar, slower at end or beginning. When in flocks, several individuals may sing simultaneously. Calls with short subdued “chit-chit, chreu-chreu...” or combinations of loud sharp shrill “chit”, “whit”, “cheu” and “titu” notes; calls may be interspersed with third and fourth song types (probably by female).

**Habitat.** Primary broadleaf evergreen forest, second growth, coastal swamp-forest, upland kerangas, selectively logged forest and, rarely, *Albizia*; at Mt Mulu (Borneo) confined to flat lowland forest on alluvial terraces and floodplains, in Java open coastal forest and low-lying primary forest. To 800 m generally, but 1200 m in Sumatra.

**Food and Feeding.** Invertebrates, including beetles (Coleoptera), surprisingly large locustids, ants (Formicidae), grubs, spiders (Araneae); also some fruits. Parties, sometimes large, move through middle storey; active, agile and rather noisy. Occasionally descends to near ground.

**Breeding.** Feb–Oct in SE Asia; in Borneo, Jul–Aug in Sarawak, breeding-condition birds May–Jul in Sabah, and May–Sept in Kalimantan. Nest, built by both sexes over 10 or more days, a neat, fairly flimsy cup, base made of dry leaves under layer of strips of palm leaves and coarse grass blades, lined with pad of fine fibre, brown downy seeds and black hair-like palm fibres, placed from near ground to up to 1.2 m up in bush or in fork of sapling. Clutch 2 eggs, whitish to creamy-brown or pale green, densely and evenly marked with pale brown or rich red-brown spots over underlying markings of pale grey or dark brown scribbling; incubation period at least 9 days. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally common resident in SE Asian range, but apparently local in Cambodia. Common in Khao Pra-Bang Kham Wildlife Sanctuary, in Thailand, and Taman Negara National Park, in Peninsular Malaysia. Common in Phou Xang He National Biodiversity Conservation Area (NBCA), Phou Xiang Thong and Xe Bang Nouan NBCAs, locally frequent in Nam Kading NBCA, and present in Xe Pian, Nakai-Nam Theun and Hin Namno NBCAs, all in Laos. In Vietnam, fairly common in Cuc Phuong and Bach Ma National Parks, and

present in Thuong Da Nhim and Chu Yang Sin Nature Reserves (S Annam), and in ten protected areas in the Annamese lowlands; fairly common in Nam Bai Cat Tien National Park (Cochinchina). In Borneo, common in Sabah, including Danum Valley Conservation Area, present in Similajau National Park (Sarawak), and common in Tanjung Puting National Park (S Kalimantan). Locally common in Sumatra, mainly in primary forest; present in Gunung Leuser, Bukit Tigapuluh and Way Kambas (common) National Parks. Present in Ujung Kulon National Park, in W Java. Numbers decline in response to fragmentation of lowland-forest habitat.

**Bibliography.** Buij *et al.* (2006), Chasen (1939), Chasen & Hoogerwerf (1941), Danielsen & Heegaard (1995), David-Beaulieu (1932), Davidson *et al.* (1997), Deignan (1963), Duckworth & Kelsch (1988), Duckworth, Tizard *et al.* (1998), Duckworth, Wilkinson *et al.* (1997), Eames (1995), Eames *et al.* (2001), Engelbach (1932), Evans & Timmins (1998), Evans *et al.* (2000), Hartert (1895), Hoogerwerf (1967, 1971), Bin Jalan & Gaidikas (1987), Johns (1989), Lambert & Collar (2002), Lê Manh Hùng *et al.* (2002), Lê Xuân Canh *et al.* (1997), Lekagul & Round (1991), MacKinnon (1988), van Marle & Voous (1988), Medway & Wells (1976), Mees (1986), Meyer de Schauensee & Ripley (1940b), Nash & Nash (1988), Neath (2001), Oberholser (1932), O'Brien & Kinnaird (1996), Parrott & Andrew (1996), Robinson (1928), Robinson & Kloss (1924b), Robson (2000), Robson, Eames, Nguyễn C. & Truong Van La (1993a), Robson, Eames, Wolstencroft *et al.* (1989), Sheldon *et al.* (2001), Smythies & Davison (1999), Sody (1956), Thewlis *et al.* (1996), Thomas & Poole (2003), Thompson (1966), Timmins & Trinh Viet Cuong (1999), Timmins & Wilkinson (1996), Voous (1950), Wilkinson, Dutson & Sheldon (1991), Wilkinson, Dutson, Sheldon, Darjono & Noor (1991).

## 124. Rufous-crowned Babbler

### *Malacopteron magnum*

**French:** Akalat géant

**German:** Rotscheitel-Zweigimalie

**Spanish:** Tordina Magna

**Other common names:** Red-headed Babbler/Tree-babbler, Greater/Larger Red-headed Babbler/Tree-babbler

**Taxonomy.** *Malacopteron magnum* Eyton, 1839, Peninsular Malaysia.

Forms a superspecies with *M. palawanense*; sometimes thought possibly conspecific. Two subspecies recognized.

**Subspecies and Distribution.**

*M. m. magnum* Eyton, 1839 – extreme S Myanmar (extreme S Tenasserim), S Thailand, Peninsular Malaysia, Sumatra, N Natuna Is and Borneo (except N).

*M. m. saba* Chasen & Kloss, 1930 – N Borneo.

**Descriptive notes.** 18–19.5 cm; 20–36 g. Mid-sized olive-brown and greyish hook-billed babbler with dull rufous crown, black nape and rufous-tinged tail. Nominative race has crown dull rufous with vague blackish scaling, becoming all black on hindcrown and nape; mantle, scapulars and back greyish-tinged olive-brown, shading darker on upperwing and to dull rufous on rump and tail; lores, supercilium, ear-coverts and lower face pale greyish with vague white streaks and some grey flecks; chin to mid-belly off-white with vague broad pale greyish streaking, lower underparts plain whitish or greyish-white; iris red to reddish-

brown; upper mandible greyish-brown, lower mandible paler horn-grey; legs pale slate to bluish-grey. Sexes similar. Juvenile is similar to adult. Race *saba* has dull rufous extending onto hindcrown, thereby confining black to nape. **VOICE.** Song consists of three main parts: first part a series of clear well-spaced notes, “phu-phu-phi-phi”, louder and more spaced than that of *M. cinereum* and usually not descending; second part a series of well-spaced even notes, sometimes slightly descending or hurried towards end, e.g. “chuwee-chuwee-chuwee-chuwu” or “chu-chi-chi-chi-chu-chu-chu-chu”; third a well-spaced, loud, very even-pitched “chut-chut chut-chut-chut-chut-chut”. When singing, male may give first type, followed, after an interval, by second type, and so on. Series of “chut” notes may be given in duet with first two song types (probably by female).

**Habitat.** Primary broadleaf evergreen forest, mixed dipterocarp forest, disturbed and selectively logged forest, upland heath and stunted ridgetop forest, transitional kerangas forest, tidal riverine swamp-forest and in Sumatra even mangroves; also abandoned rubber and older *Albizia* plantations, and rarely cocoa; appears to prefer primary forest. To 455 m in SE Asia generally; to 800 m in Sumatra and 1000 m in Borneo (Kalimantan).

**Food and Feeding.** Insects, including black beetles (Coleoptera), soft greenish insects, grasshoppers (Orthoptera), ants (Formicidae); some seeds. Forages mostly in middle storey, also in lower branches of taller trees and in undergrowth, not descending to ground; gleans foliage. Found in pairs or small parties, sometimes in association with other species, including other babblers, in bird waves.

**Breeding.** Mar–May in SE Asia; May–Jun in Sumatra; in Borneo, Aug–Sept in Sarawak and Mar, May–Jul and Oct in Sabah. Nest described as a cup, made of dead leaves, grass and dead moss, lined with roots, placed up to 1 m above ground in thick bush or small sapling. Clutch 2 eggs, rich salmon-pink with crimson flush at large end, with wavy lines and few spots of deep crimson-brown, fairly numerous at large end but sparse elsewhere, or pale blue with dark reddish to crimson blotches and spots. No further information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Uncommon to fairly common from S Myanmar and S Thailand into Peninsular Malaysia; less common than *M. cinereum* in Sumatra. Common in Taman Negara National Park, in Peninsular Malaysia. Present in Gunung Leuser, Bukit Tigapuluh and Way Kambas (common) National Parks, in Sumatra. Common throughout lowland mixed dipterocarp forest in Borneo, including Danum Valley Conservation Area (Sabah); frequent in Berau district forest (E Kalimantan), and very common at Barito Ulu; present in Similajau National Park (Sarawak), and common in Tanjung Puting National Park (S Kalimantan). As a Sundaic lowland-forest species, this babbler is highly susceptible to extensive forest destruction throughout its range; ability to survive in second growth implies no immediate risk, although numbers decline in response to logging of lowland-forest habitat.

**Bibliography.** Anon. (2006d), Buij *et al.* (2006), Butchart & Stattersfield (2004), Chasen (1939), Chasen & Hoogerwerf (1941), Collar *et al.* (2001), Danielsen & Heegaard (1995), Deignan (1963), Duckworth & Kelsch (1988), Duckworth *et al.* (1997), Eames (2005), Hartert (1895), Holmes (1966), Hume & Davison (1878), Johns (1989), Lambert (1992), Lambert & Collar (2002), Lekagul & Round (1991), van Marle & Voous (1988), Medway & Wells (1976), Nash & Nash (1988), O'Brien & Kinnaird (1996), Parrott & Andrew (1996), Robinson (1928), Robson (2000), Sheldon *et al.* (2001), Smythies (1986), Smythies & Davison (1999), Stattersfield & Capper (2000), Thompson (1966), Voous (1950), Wilkinson, Dutson & Sheldon (1991), Wilkinson, Dutson, Sheldon, Darjono & Noor (1991).

## 125. Melodious Babbler

### *Malacopteron palawanense*

**French:** Akalat de Palawan **German:** Palawanzweigimalie **Spanish:** Tordina de Palawan  
**Other common names:** Palawan Babbler, Red-headed Tree-babbler

**Taxonomy.** *Malacopteron palawanense* Büttikofer, 1895. Puerto Princesa, Palawan, Philippines. Forms a superspecies with *M. magnum*; sometimes thought possibly conspecific. Monotypic.  
**Distribution.** Palawan and Balabac, in W Philippine Is.

**Descriptive notes.** 17–18 cm; 28–37 g. Medium-sized olive-brown and buffy hook-billed babbler with dull rufescent forecrown, rump and tail. Forecrown is dull rufescent brown with vague blackish scaling, becoming browner on hindcrown and nape; mantle, scapulars and back rufescent olive-brown, shading darker on upperwing and to dull rufous on rump and tail; lores, supercilium and area around eye ashy grey, ear-coverts and lower face pale greyish-tan with vague buffy shaft streaks and grey flecks, submoustachial area greyish with whitish flecks; chin, throat and upper breast silky white with very indistinct and sparse grey streaking, breast and flanks greyish-buff, shading paler and buffier on mid-belly; iris yellow to almost white; upper mandible black, lower mandible paler; legs greyish slate-blue. Sexes similar. Juvenile apparently undescribed. **Voice.** Song a loud series of mournful clear whistles increasing in volume, with alternating high and low notes, e.g. “hi-hu-hi-hu-hi” or “hi-hu-hi-hu-hi-hu-hi”, accompanied by stressed antiphonal harsh whiplash, “whit-whit-whit-whit”, or slightly uneven weak “chi-chi-chi-chi”, sometimes given by more than one other bird.

**Habitat.** Primary and old secondary lowland evergreen forest, bamboo, forest edge, usually in tangles and vines in middle storey or in tops of low trees; lowlands to perhaps 100 m.

**Food and Feeding.** No information on diet; presumably small invertebrates and some vegetable matter. Forages singly or in small groups, rather sluggishly, in middle and sometimes lower storey; disturbs prey from bunches of dead leaves trapped in bamboo canopy.

**Breeding.** Birds in breeding condition in Feb–Mar and May. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species; present in Palawan EBA. Formerly considered Endangered. Uncommon. Possibly an extreme lowland-forest specialist, but in mid-1990s reported as being at good densities in remaining pockets of such habitat. Not known to be present in St Paul’s Subterranean River National Park, however, and best “protected” area for it is apparently Iwahig Penal Colony, outside Puerto Princesa.

**Bibliography.** Anon. (2006d), Butchart & Stattersfield (2004), Collar *et al.* (2001), Dickinson *et al.* (1991), Hachisuka (1935), Hartley & McGowan (1991), Hornsokov (1996), Kennedy *et al.* (2000), duPont (1971), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Voous (1950), Whitehead (1890).

## Genus *OPHRYDORNIS* Büttikofer, 1895

## 126. Grey-breasted Babbler

### *Ophrydornis albogularis*

**French:** Akalat à gorge blanche **German:** Graubrust-Zweigimalie **Spanish:** Tordina Pechigris  
**Other common names:** White-throated Babbler

**Taxonomy.** *S[etaria]*, *albogularis* Blyth, 1844. “Singapore”.

Usually placed in genus *Malacopteron*, but differs in appearance and behaviour, and bill rather more broad-based. Two subspecies recognized.

**Subspecies and Distribution.**

*O. a. albogularis* (Blyth, 1844) – Peninsular Malaysia and Sumatra.

*O. a. moultani* Robinson & Kloss, 1919 – Borneo.

**Descriptive notes.** 14–16 cm; 13–23 g. Small hook-billed, rather short-tailed babbler, rather muscipid-like in appearance, with dark grey head, white supercilium, white underparts with pale grey breastband. Nomininate race has crown and ear-coverts dark sooty grey, intersected by narrow white supercilium from above lores to just behind eye; lores and area under eye to lower ear-coverts blackish-grey; upperparts and upperwing dark greyish olive-brown, becoming paler and more chestnut on rump and base of tail; chin, submoustachial area and throat pure white, shading abruptly to ashy-grey breastband, this in turn shading abruptly

to creamy-white mid-belly and buffy flanks, thighs and vent; iris crimson; bill black above, grey-blue below; legs blue to bluish-grey. Sexes similar. Juvenile apparently undescribed. Race *moultani* has paler buff flanks than nominate, and in N Borneo (Sabah) lores described as yellow. **Voice.** Song a rather long, subdued, discordant series of ascending “whu-whi”, “whit-whu”, and “uu-whu” phrases (and variants), sometimes interspersed with short “chit” notes. Call “trr”; in alarm this becomes persistent churring.

**Habitat.** Understorey of forest, generally preferring forests on poor soils below the steepland boundary or in alluvial terraces: broadleaf evergreen forest, lightly logged forest, freshwater peat-swamp forest dominated by “ramin” (*Grisebahi*), and in some areas confined to lowland peat-swamp and kerangas forest; also *Albizia* *falcataria* groves, dryland dipterocarp forest, mixed dipterocarp forest, and, in Barito Ulu (Kalamantan, in Borneo), steep rocky terrain. In E Kalimantan found three times in primary forest on sandy soil, once in dry creek and twice in swampy forest. Lowlands in Peninsular Malaysia: 120–915 m in Borneo.

**Food and Feeding.** Insects, including ants (Formicidae) and hoppers (Homoptera). Found singly or in pairs, sometimes in small parties of up to five individuals; avoids bird waves. Hops sideways along branches. Forages from just above ground to 2 m, movements resembling *Stachyris* more than *Malacopteron*.

**Breeding.** Jul–Aug in Sumatra and May–Jun in Borneo. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Scarce and local in Peninsular Malaysia, notably (at least in 1990s) at Pasoh Forest Reserve. Sparse in lowland forests of Borneo, and either rare or absent in N & E of island, but common on R Murung and E Busang (Barito Ulu); present in Similajau National Park (Sarawak), Gunung Palung National Park (W Kalimantan) and Tanjung Puting National Park (S Kalimantan). Few records from Sumatra, but probably overlooked; present in Bukit Tigapuluh and Way Kambas (rare) National Parks. Swamp-forest destruction has been so extensive in Indonesian Borneo that it was predicted in 2000 that all primary formations would have disappeared by 2010, and situation is little different in Malaysian Borneo; the species’ ability to survive in second growth, and to some extent in other habitats, however, implies that it is not immediately at risk. Nonetheless, numbers decline in response to fragmentation of lowland-forest habitat.

**Bibliography.** Anon. (2006d), Butchart & Stattersfield (2004), Chasen (1939), Collar *et al.* (2001), Danielsen & Heggard (1995), Duckworth & Kersh (1988), Duckworth *et al.* (1997), Dutton *et al.* (1991), Gönner (2000), Holmes (1996, 1997), Holmes & Wall (1989), Lambert & Collar (2002), van Marle & Voous (1988), Medway & Wells (1970, 1976), Nash & Nash (1988), Parrott & Andrew (1996), Robson (2000), Sheldon (1987), Sheldon *et al.* (2001), Smythies & Davison (1999), Stattersfield & Capper (2000), Voous (1950), Wilkinson, Dutton & Sheldon (1991), Wilkinson, Dutton, Sheldon, Darjono & Noor (1991).

## Genus *MALACOCINCLA* Blyth, 1845

## 127. Abbott’s Babbler

### *Malacocincla abbotti*

**French:** Akalat d’Abbott **German:** Rotschwanz-Maustimalie **Spanish:** Tordina de Abbott  
**Other common names:** Common Brown Babbler

**Taxonomy.** *[Malacocincla]*, *Abbotti* Blyth, 1845, Ramree Island, Arakan, Lower Myanmar.

Often placed in genus *Trichastoma*. Mainland races weakly differentiated, and perhaps only *concreta* and *baweana* worthy of recognition. Proposed races *amabile* (low elevations from E Nepal E to E Assam, in NE India) and *rufescentior* (from S Myanmar and S Thailand) both merged with nominate. Individuals of this species observed in SE part of NE Thailand, SW Laos and adjacent NE Cambodia have not been assigned to race. Eight subspecies tentatively recognized.

**Subspecies and Distribution.**

*M. a. abbotti* Blyth, 1845 – Nepal and extreme S Bhutan E to NE Indian states, E Bangladesh, SW & S Myanmar (including Tenasserim), W & S Thailand and NW Peninsular Malaysia.

*M. a. krishnarajui* Ripley & Beehler, 1985 – Eastern Ghats (Orissa, NE Andhra Pradesh), in E India.

*M. a. altera* (Sims, 1957) – C Laos and Vietnam (N & C Annam).

*M. a. williamsoni* Deignan, 1948 – E Thailand E to E Cambodia and S Vietnam (Cochinchina).

*M. a. olivacea* (Strickland, 1847) – SE Thailand.

*M. a. obscurior* Deignan, 1948 – extreme SE Thailand, Peninsular Malaysia (except NW), Singapore and Sumatra.

*M. a. concreta* Büttikofer, 1895 – Belitung I, and Borneo (including Matasiri I, off S).

*M. a. baweana* Oberholser, 1917 – Bawean I, off NE Java.

**Descriptive notes.** 15–17 cm; 26–32 g. Medium-sized hook-billed babbler, chunky, rather short-tailed and nondescript, brown above and greyish-white to buff-tan below, with vague eyering and eyebrow. Nomininate race has crown, upperparts and upperwing dull olive-brown, crown with weak buff shaft streaks (not visible in field), tail slightly browner and with strong rufescent wash basally; lores and supercilium greyish, ear-coverts and neck side buffy olive-brown, submoustachial area buffish-grey; chin, throat and upper breast greyish-white, shading on breast side, flanks and belly to buffy rufous and on lower flanks, thighs and vent to bright

rufous-buff; iris light brown or reddish-brown; upper mandible blackish-horn, lower mandible paler; legs brownish-flesh. Sexes similar. Juvenile has crown and upperparts dark rufescent brown (similar to adult *Trichastoma bicolor*). Race *krishnarajui* has more olive upperparts than nominate, with uppertail and rump deeper brown, more extensive greyish-white on upper breast, flanks paler, vent richer rufescent; *williamsoni* is darker and more olivaceous-brown above than nominate, with darker crown; *altera* is like previous, but crown duller, forehead less streaked, upperparts duller (more chestnut), throat greyer and more distinctly streaked, breast more ashy-washed, flanks paler; *olivacea* is very like nominate, but throat and breast dirtier greyish-white with very vague streaking; *obscurior* is slightly darker above, slightly more rufescent on lower underparts; *concreta* is much more uniformly greyish-white below, with much more restricted and paler buff-rufous area on lower flanks to vent; *baweana* resembles last, but paler above and below, even less rufescent on rump and tail. **Voice.** Song consists of repeated variable loud jolly phrases, usually of 3 (sometimes up to 5) well-spaced notes, e.g. “chuu-woo-woo, wuu-woo-wuu” and “wi-wu-yu-wi”, also described as variable short series of 3–4 rich, fluty, liquid, slurred, short whistled notes, some halting, some hurried, usually in alternating directions, e.g. “fwew, fwewfwewééé!... fwew, fwewfwé-fwew... fwew, fwewfwéew”. In duet one bird sings clear whistled “wee-oh wee-oh a-where” or “peevs-wherea where”, other giving 1–3 descending, plaintive calls. In Sumatra consists of 6 notes with rising inflection, a barely audible introductory note followed by 4 evenly spaced slurred whistles and a final loud upslurred whistle, female uttering 2–3 sharp notes in unsynchronized duet. Calls include soft mewling notes, a pulsing, purring trill when agitated, and short, harsh, explosive “cheu” notes interspersed with high nervous “wer” notes; evening group-calling involves spattering “tu-churr churr churr churr”, low and slurred, last note higher and inflected.

**Habitat.** Degraded broadleaf evergreen and semi-evergreen forest, riverine forest and swampy coastal scrub, peat-swamp-forest, back edges of mangroves, nipa palm and transitional habitats, mixed plantation-natural forest, secondary growth, forest edges along banks of streams, normally

frequents thickets and edge habitat, especially second growth, only exceptionally on fringe of primary forest. In Borneo prefers low-altitude riverine and coastal areas, coastal scrub, especially with nipa or mangroves, fire-padang scrubland and secondary or poor-soil forests. Up to 1100 m. **Food and Feeding.** Insects and small invertebrates. Solitary or in pairs, on or near ground. Forages with deliberate slow movements among leaf litter, investigating niches in low tangled vegetation; often tame.

**Breeding.** Apr–May in Bhutan, Jan–Sept in SE Asia, at least Dec–Jan in Sumatra, and in Borneo May–Jun in Brunei and Jul–Aug in Kalimantan; possibly multi-brooded, second brood documented for at least 38% of pairs in one season in Thailand. Nest a bulky, open, sometimes deep cup, made of dead leaves, bracken fronds, weed stems, moss, grasses, black fern roots and rootlets, lined, often scantily, with rather coarse red roots, fine hair-like fibres, black fungal hyphae, fine black fern stems and leaf stalks, placed in bush, briars, weeds, clump of creepers or ferns, base of frond in spiny rattan (*Calamus*) or fan palm, 0.5–1.8 m above ground, possibly sometimes on ground; of 17 active nests in Thailand, 15 were in rattan palm and two in small unidentified saplings. Clutch 2–5 eggs, mostly 3, whitish or pale pinkish-white to bright salmon, sparingly marked with spots, blotches and squiggles of reddish-brown or brown and ink-purple or lavender; incubation period 14–15 days; nestling period 11 days; post-fledging dependence period 7–9 weeks; second brood begun before previous one finally disperses, male adult then caring for previous brood and female attempting to provision nestlings alone. Occasional brood parasitism by Violet Cuckoo (*Chrysococcyx xanthorhynchus*) reported. Nest predation main cause of failure in one study in Thailand.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common in much of its range in appropriate habitat, and common in parts of SE Asian range. Very rare and local in Nepal except in far E, where common. Rare resident in lower foothills in Bhutan, having been fairly common near Gelephu in 1967 before forest there cleared. Locally common in India, where common in Nameri and Kaziranga National Parks (Assam), and elsewhere in NE India present in e.g. Buxa Tiger Reserve (West Bengal), with 5 birds/km<sup>2</sup> in semi-evergreen forest and 9–7 birds/km<sup>2</sup> in mixed plantation and natural forest, also in Balphakram National Park (Meghalaya) and Ngengpui Wildlife Sanctuary (Mizoram). Common in Sundarbans East Wildlife Sanctuary, in Bangladesh, but otherwise very local in that country. Fairly common in Thailand, with 13 pairs in 30 ha of forest plot in Khao Yai National Park. Fairly common (at least before 1970) in Cambodia. In Laos, common in Phou Xang He National Biodiversity Conservation Area (NCBA), occasional in Xe Pian NBCA and Dong Hua Sao NBCA, and present in Phou Xiang Thong NBCA. In Vietnam, present in four protected areas in the Annamese lowlands, and common in Bach Ma National Park and fairly common in Nam Bai Cat Tien National Park. Common in Taman Negara National Park, in Peninsular Malaysia. Local in Borneo, where up to 1994 only 21 documented records could be found; rare in Sabah, but present in Similajau and Bako National Parks and Semenggo Forest Reserve, in Sarawak, and Tanjung Puting National Park (common in nipa), in S Kalimantan, and common in scrub in grassland N of Banjarmasin. Present in Gunung Leuser and Way Kambas National Parks, in Sumatra, rare in latter, but common around Bagansiapiapi (on N coast); very common in the now destroyed Padang-Sugihan Wildlife Reserve, in S Sumatra.

## 128. Horsfield's Babbler

### *Malacocincla sepiaria*

**French:** Akalat de Horsfield **German:** Horsfieldmaustimalie **Spanish:** Tordina de Horsfield  
**Other common names:** Horsfield's Jungle Babbler, Rusty-brown Babbler; Koengke/Vanderbilt's Babbler ("vanderbilti")

**Taxonomy.** *Brachypteryx sepiaria* Horsfield, 1821, Bogor, Java.

Previously thought to be conspecific with *M. perspicillata*. Form described from Aceh (N Sumatra) as "*M. vanderbilti*" now known to be synonym of race *barussana* of present species. Proposed race *liberalis* (NW Sumatra) merged with *barussana*, and *minor* (E Java and Bali) with nominate. Five subspecies recognized.

**Subspecies and Distribution.**

*M. s. tardinata* E. J. O. Hartert, 1915 extreme S Thailand and Peninsular Malaysia.

*M. s. barussana* Robinson & Kloss, 1921 – Sumatra.

*M. s. harterti* Chasen & Kloss, 1929 – N Borneo.

*M. s. rufiventris* Salvadori, 1874 – S Borneo.

*M. s. sepiaria* (Horsfield, 1821) – Java and Bali.

**Descriptive notes.** 15–16 cm; 25–33 g. Nominative race has crown dark brown, noticeably darker and greyer than olive-brown upperparts, upwelling and short tail; lores and supercilium pale grey, ear-coverts and neck side slightly streaky buff-brown; chin, submoustachial area and throat whitish, lower throat and upper breast with vague greyish-buff streaks, breast and upper flanks greyish-buff, shading to whitish on belly and buffy ochre on lower flanks, thighs and vent; iris red to brown; upper mandible blackish-horn, lower mandible yellowish-grey; legs grey to fleshy-purple. Differs from very similar *M. abbotti* in

being shorter-tailed, darker above, especially on crown (which lacks pale streaks), and in having streaks on upper breast. Sexes similar. Juvenile has upperparts rather more rufous than adult. Race *tardinata* has brighter ochraceous flanks and vent than nominate, extending over lower belly; *barussana* is generally darker than nominate, with distinctly greyer throat and upper breast, flanks dark ochre; *rufiventris* is richer and slatier above, more obviously streaked throat and upper breast, ochraceous-grey breastband, and much richer and more extensive buff-ochre on lower underparts;

*harterti* is like last, but underparts rather less richly coloured, crown and nape on average slightly less grey. Voice. Usual song a strident, clearly spaced "wi-cho-teu" or "tip-top-tiu", first note high and sharp, second short and lowest, third high and shrill; variations occur, particularly when excited, and first note sometimes omitted. Song in Java a plodding, unevenly spaced, often 4-note series, with longer, rising end note, "wip-chup-chu-puiii" or "chip-wip-chu-puiii", sometimes a 3-note "wip-pip-pui" or "wip-chup-puiii". Call a harsh explosive "whit-whit-whit...", interspersed with quieter "wer" notes.

**Habitat.** Broadleaf evergreen forest, usually bordering streams or near water (described once as preferring dark places shaded by tangles of big looping lianas on valley slopes in hilly forest, but better evidence of such choice needed); also logged and old secondary forest, *Albizia* and *Gmelina*. Lowlands to 700 m in Thailand and Peninsular Malaysia, 300–1400 m in Sumatra, generally up to 1700 m in Borneo and Java.

**Food and Feeding.** Insects, including small locustids, beetles (Coleoptera, including weevils), butterflies and their pupae (Lepidoptera), ants (Formicidae) and grubs. Forages on ground and in low vegetation, sometimes in middle storey up to 15 m; often works its way up large creeper-covered trees. Found singly, in pairs or in small parties.

**Breeding.** Apr–May in Peninsular Malaysia, Feb–May (but apparently all months except Jul) in Java, and Feb–Sept and Nov in Borneo. Nest a broad, rather slight, untidy cup, made of dead (sometimes large) leaves, lined with fine black rootlets, fine twigs and fine fibres, placed up to 1 m above ground in sapling or more concealed site. Clutch 2 eggs, reportedly pink with reddish squiggles in Java. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare in Thailand. Fairly common to common in Peninsular Malaysia, where common in Taman Negara National Park. Locally common in lowland forested areas of Borneo; common in Sabah, including Danum Valley Conservation Area; present in Similajau National Park (Sarawak), Gunung Palung National Park (W Kalimantan), Kayan Mentarang National Park (E Kalimantan), and common but perhaps local in Tanjung Puting National Park (S Kalimantan). Present in Gunung Leuser National Park, in Sumatra. Common in Gunung Gede-Pangrango National Park and present in Ujung Kulon National Park, in W Java; recorded in more than 30% of surveys at two localities inside Alas Purwo National Park, in E Java. **Bibliography.** Andrew (1985), Buij *et al.* (2006), Chasen (1939), Chasen & Hoogerwerf (1941), Chasen & Kloss (1930), David & Gosselin (2002a), Deignan (1963), Duckworth *et al.* (1997), Grantham (2000), Holmes (1997), Hoogerwerf (1950a, 1966, 1971), Lekagul & Round (1991), MacKinnon (1988), van Marle & Voous (1988), Medway & Wells (1976), Mees (1995), Meyer de Schauensee & Ripley (1940b), Nash & Nash (1988), O'Brien & Kinnaird (1996), Robinson (1928), Robinson & Kloss (1924b), Robson (2000), Sheldon *et al.* (2001), Smythies & Davison (1999), Sody (1956), Thompson (1966), Voous (1948), Wilkinson, Dutton & Sheldon (1991), Wilkinson, Dutton, Sheldon, Darjono & Noor (1991).

## 129. Black-browed Babbler

### *Malacocincla perspicillata*

**French:** Akalat à sourcils noirs

**German:** Schwarzbrauen-Maustimalie

**Spanish:** Tordina Cejinegra

**Taxonomy.** [*Cacopitta*] *perspicillata* Bonaparte, 1850, Java; error = Borneo.

Previously thought to be a local race of *M. sepiaria* or to be conspecific with equally enigmatic (and now discredited) "*M. vanderbilti*", but now considered a valid species. Monotypic.

**Distribution.** S Borneo.

**Descriptive notes.** c. 15–16 cm. Has drab brown crown, broad brownish-black supercilium from above bill to side of nape, crown shading to vague dull greyish-brown on nape, this in turn shading to dull rufous-brown on upperparts, upwelling and tail; feathers of rump and lower flanks copious and fluffy; lores whitish with blackish area in front of eye, cheek and ear-coverts slightly brown-stained pale grey, latter with whitish shaft streaks, apparently a whitish eyering at least on lower half of eye; chin and throat whitish, shading to pale grey on cheek and breast, with narrow whitish streaks on grey breast, belly shading from pale

grey to dull rufous-brown on flanks, lower belly and undertail, central belly mixed with some mid-grey; iris colour not known; bill rather long and strong, with clear hook, blackish-brown basally and along culmen, becoming paler distally; legs dull brownish. Sexes presumably similar. Juvenile unknown. Voice. No information.

**Habitat.** Probably lowland forest of some type.

**Food and Feeding.** No information; diet presumably small invertebrates and some vegetable matter. Relatively short tarsi of the only specimen suggest that it may be more arboreal than are its congeners.

**Breeding.** No information.

**Movements.** Presumed resident.

**Status and Conservation.** VULNERABLE. Often reckoned to be extinct. Restricted-range species: responsible for defining Kalimantan Lowlands Secondary Area. Known from a single specimen of uncertain provenance, but most likely collected around Martapura (or possibly Banjarmasin), in S Kalimantan, between 1843 and 1848. Numbers likely to have declined in recent decades as a result of extensive forest destruction in the region; all original lowland habitat around Martapura has disappeared. Pleihari Martapura Nature Reserve, although now consisting of severely degraded hilly forest, is supposed to cover 300 km<sup>2</sup> at 200–1170 m elevation, and is probably the best place to search for this species.

**Bibliography.** Anon. (2006d), Bonaparte (1850), Butchart & Stattersfield (2004), Collier *et al.* (2001), Hoogerwerf (1966), MacKinnon & Phillips (1993), Mees (1995), Smythies & Davison (1999), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

## 130. Short-tailed Babbler

### *Malacocincla malaccensis*

**French:** Akalat à queue courte

**German:** Kurzschwanz-Maustimalie

**Spanish:** Tordina Colicorta

**Taxonomy.** [*Brachypteryx*], *malaccensis* Hartlaub, 1844, Malacca, Peninsular Malaysia.

Has been placed in genus *Trichostoma*. Forms a superspecies with *M. cinerea*; may perhaps be conspecific, but song very different. Populations in parts of Borneo have been regarded as

subspecifically distinct, but variation slight and probably clinal; proposed races *sordida* (NE Borneo) and *samurai* (Bangka, Belitung, and W. Borneo) both considered synonymous with *poliogenys*. Proposed race *feriata* (from Mt Mulu, in NW Borneo), based on single specimen, has characters apparently exhibited by juveniles of this species. Two subspecies recognized.

#### Subspecies and Distribution.

*M. m. malaccensis* (Hartlaub, 1844) – S Thailand, Peninsular Malaysia, Singapore, Sumatra and its islands, Anambas Is and Natuna Is.

*M. m. poliogenys* (Strickland, 1849) – Bangka, Belitung and Borneo.

**Descriptive notes.** 13.5–14.5 cm; 18.5–28 g. Like a small version of *M. abbotti*, but with very short (often cocked) tail, thinner bill, greyish ear-coverts and blackish moustachial stripe against strong white throat. Nominative race has crown dark ochrous-brown, nape, mantle and back slightly paler, shading to slightly rufescent rump, with brown upwringing and very short tail fringed chestnut; face (lores, supercilium, ear-coverts and neck side) dull grey, slightly darker under eye, where merges into dark grey or blackish moustachial stripe; chin, submoustachial area and throat to lower belly silky white, breast side to lower flanks pale

warm buff, vague pale warm buff wash across breast; iris red to brown; upper mandible blackish, lower mandible often paler; legs usually flesh-coloured or pinkish, sometimes grey. Sexes similar. Juvenile has paler brown cap, head side tinged brown, rusty outer fringes of primaries, ochrous-buff throat. Race *poliogenys* has slightly more rufescent crown than nominate, slightly less rufescent wing fringes, rump and tail, more slaty-grey wash on upperparts, and much stronger and darker warm buffy breast wash and flanks. **Voice.** Song a series of 6–7 loud rich whistled notes, descending in pitch, introduced by dry trill, “pi’pi’pi’pi’pi’pew pew pew pew pew”; reportedly given as duet by pair-members, with very high level of co-ordination, but single birds respond to tape playback and give entire song alone. In Sumatra, reported duet initiated by female with barely audible downslurred whistle, short pause, then sequence of 6 downslurred and progressively longer notes, immediately picked up and repeated by male. Calls with low, harsh, crackling, rattling sounds and a harsh, mechanical “chututututut...”, interspersed with soft “yer” notes; also “fit-zweet” and “fit-fit-zweet”, and rapidly repeated “pew”.

**Habitat.** Primary broadleaf evergreen forest and secondary growth, drier parts of peatswamp-forest, stream edges, scrub, thickets, older *Albizia* plantations adjacent to forest, overgrown rubber, sapling bamboo thickets; kerangas pole forest at Similajau National Park (NW Borneo). To 1000 m.

**Food and Feeding.** Insects, including black beetles (Coleoptera), small grasshoppers (Orthoptera) and ants (Formicidae). Usually forages just above or on ground, singly or more usually in pairs.

**Breeding.** Feb–Sept throughout range, but in Borneo also birds in breeding condition in Nov and nestling in Jan; possibly multi-brooded. Nest a neat cup, sometimes semi-roofed with large dead leaves, made of fine twigs, root fibres or leaves, lined with grass-like material or fine roots and tendrils, placed up to 0.3 m above ground among fallen twigs or small saplings, or on ground and concealed by small saplings between buttresses of tree or inside large curled-up dead leaf. Clutch 2–3 eggs, pale creamy buff to pinkish-red with spots, streaks or squiggles of rich brown to reddish and sometimes pale mauve. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Fairly common to common in continental range. Common in Taman Negara National Park, in Peninsular Malaysia. Locally common in Borneo, and common in Danum Valley Conservation Area (Sabah); fairly frequent in Berau district forest (E Kalimantan); present in Similajau National Park (Sarawak) and common in Tanjung Puting National Park (S Kalimantan). Present in Gunung Leuser and Way Kambas National Parks, in Sumatra, frequent in latter; recorded from the now destroyed Padang-

Sugihan Wildlife Reserve, in S Sumatra. A Sundic lowland-forest species, thus highly susceptible to the extensive forest destruction throughout its range, although ability to survive in second growth and hill-slope forest implies that it is not immediately at risk.

**Bibliography.** Anon. (2004), Bai *et al.* (2006), Borenart & Stattersfield (2004), Chavén (1939), Chasen & Hoogerwerf (1941), Collar *et al.* (2001), Danielsen & Heegaard (1995), Deignan (1963), Duckworth & Keish (1988), Duckworth *et al.* (1997), Eames (2005), Hartert (1895), bin Jalan & Galdikas (1987), Johns (1989), Lekagul & Round (1991), Löffing (1984), van Marle & Voous (1988), Medway & Wells (1976), Mees (1986), Nash, S.V. & Nash (1985a, 1987c, 1988), Oberholser (1932), O’Brien & Kinnaird (1996), Parrot & Andrew (1996), Rajathurai (1996), Robinson (1927), Robson (2000), Sheldon *et al.* (2001), Smythies & Davison (1999), Stattersfield & Capper (2000), Thompson (1966), Wilkinson, Dutson & Sheldon (1991), Wilkinson, Dutson, Sheldon, Darjono & Noor (1991).

## 131. Ashy-crowned Babbler

### *Malacocincla cinereiceps*

**French:** Akalat à tête cendrée **German:** Graukopf-Maustimalie **Spanish:** Tordina Coronigris  
**Other common names:** Ashy-headed Babbler

**Taxonomy.** *Drymocapthus cinereiceps* Tweeddale, 1878, Puerto Princesa, Palawan, W Philippines. Has been placed in genus *Trichostoma*. Forms a superspecies with *M. malaccensis*; may perhaps be conspecific, but song very different. Monotypic.

**Distribution.** Palawan and Balabac, in W Philippine Is.

**Descriptive notes.** 13 cm; 22–26 g. Has crown to nape dull darkish grey, upperparts, upperwing and tail dull rufous-tinged ochrous-brown; lores, cheek and ear-coverts pale grey, moustachial streak as crown; chin, submoustachial area and underparts white, except for pale brownish-ochre narrow breastband and breast side, flanks, thighs and vent; iris brown to chestnut; upper mandible blackish-grey, lower mandible pearly pinkish; legs pearly pinkish. Differs from very similar *M. malaccensis* in colours of crown, hindneck and upperparts, much paler grey ear-coverts and cheek, rendering dark moustachial stripe more

obvious, and buff of underparts discoloured to brownish-ochre. Sexes similar. Juvenile apparently undescribed. **Voice.** Song a series of 4–9 husky, stressed, forced, nasal “jheuw”, “chieuw” or “jheuw” notes, e.g. “jhieu-jhieu-jhieu-jhieu...”, sometimes with 1–4 brief weak stuttering introductory notes; song lasts 3–5 seconds, repeated after c. 8 seconds.

**Habitat.** Primary and secondary broadleaf evergreen forest, second growth and scrub, to 1300 m. **Food and Feeding.** No information on diet; presumably small invertebrates and some vegetable matter. Found singly or in pairs, foraging near or on ground, behaving very much as *M. malaccensis*. Inquisitive, responding to “pishing”; flicks wings lightly when on the move.

**Breeding.** Apr–Sept. Nest described as a cup, made of grasses, rattan fibres and dead bamboo leaves, lined with mosses and lichens, placed on ground at base of rattan. Clutch 2 eggs, off-white and covered with red/brown spots (more numerous at broader end), or blue and thickly speckled with dark brown. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Palawan EBA. Fairly common.

**Bibliography.** Delacour & Mayr (1946), Dickinson *et al.* (1991), Hachisuka (1935), Hartley & McGowan (1991), Kennedy *et al.* (2000), McGregor (1909), duPont (1971), Stattersfield *et al.* (1998), Whitehead (1890).

# Genus *TRICHASTOMA* Blyth, 1842

## 132. White-chested Babbler

### *Trichastoma rostratum*

**French:** Akalat à front noir **German:** Mangrovemaustimalie **Spanish:** Tordina Pechiblanca  
**Other common names:** Blyth's (Jungle) Babbler, Mangrove Babbler

**Taxonomy.** *Trichastoma* [sic] *rostratum* Blyth, 1842, Singapore.  
Two subspecies recognized.

#### Subspecies and Distribution.

*T. r. rostratum* Blyth, 1842 – extreme S Myanmar (extreme S Tenasserim), S Thailand, Peninsular Malaysia, Singapore, Sumatra (including Riau Archipelago and Lingga Archipelago) and Belitung.  
*T. r. macropteron* (Salvadori, 1868) – Borneo, including Banggai I.

**Descriptive notes.** 15 cm; 20.5–23 g. Smallish babbler, brown above and white below, with rather long narrow hook-tipped bill and shortish tail. Nominate race has crown brown with slightest greyish tinge, upperparts brown with slightest rufescent tinge, upperwing and tail with dull rufous-chestnut fringes; face (lores, supercilium, ear-coverts, cheek) buffy brown, chin and submoustachial area to vent silky white with soft grey breast side and flanks, lower flanks with buffy tinge; iris brown; bill black above, horn below; legs pale flesh or greyish-brown. Sexes similar. Juvenile is similar to adult. Race *macropteron* has

mantle to rump slightly more olive-tinged, less rufescent, than nominate. **Voice.** Song a repeated, quite high-pitched, clear “wi-ti-tiu”, “chui-chwi-chew” or “chwi-chi-chee”, sometimes introduced with short trill, “chr chr ooi-uee”; at least seven distinct variations (seemingly common to all individual singers) in Sumatra, involving 3–5 notes, with first note either a harsh whistle or a short buzz and last note either rising or falling in pitch. Female may give loud “teew” with sharp falling inflection every 0.6 seconds, 2–4 times, during male song. Calls with harsh, scolding rattles.

**Habitat.** Riverine broadleaf evergreen forest and secondary growth, lightly logged forest, mangroves, upland heath and peatswamp-forest, coastal habitat on (larger) offshore islands, beach-stand scrub, abandoned old rubber plantations, older *Albizia* plantations, low bushes of streambanks and damp valley bottoms, usually near water; regarded as a forest-riverbank specialist, and often seen (from canoes) by streambanks in upper reaches of rivers. To 200 m.

**Food and Feeding.** Grubs and insects. Usually in pairs. Forages on ground, hopping about rocks, trunks, branches and roots at water's edge; also sallying after insects.

**Breeding.** Mar–Jun in SE Asia. Nest, built by both sexes over 18 days or more, a loose deep cup made of dead leaves, which may be collected from pond when wet (birds have been observed apparently wetting lining materials before adding them to nest), and strips of dried palm fronds, roughly lined with fine fibres and rootlets, placed 0.4–1.2 m above ground in base of ground palm or hidden in small rattan. Clutch 2 eggs, pale greenish, spotted and blotched with dark greenish-brown. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Generally fairly common to common in continental part of range, but now rare in Singapore; common in Taman Negara National Park and Kuala Selangor National Park, in Peninsular Malaysia. Locally common throughout lowland mixed dipterocarp forest in Borneo, and judged common in Sabah, including Danum Valley Conservation Area; frequent in Berau district forest (E Kalimantan) and rather common in Barito swamp region (S Kalimantan); present in Similajau National Park (Sarawak), and common in Tanjung Puting National Park (S Kalimantan). Uncommon in Sumatra, where present in Gunung Leuser, Bukit Tigapuluh (locally very common) and Way Kambas (scarce) National Parks; recorded from the now destroyed Padang-Sugihan Wildlife Reserve, in S Sumatra. A Sundaic lowland-forest species, thus highly susceptible to the extensive forest destruction throughout its range, although ability to survive in second growth and overgrown plantations implies that it is not immediately at risk.

**Bibliography.** Anon. (2006d), van Balen & Prentice (1997), Bransbury *et al.* (1994), Buij *et al.* (2006), Burchard & Stattersfield (2004), Chasen (1939), Collar *et al.* (2001), Danielsen & Heegaard (1995), Deignan (1963), Duckworth & Kelsh (1988), Duckworth *et al.* (1997), Eames (2005), Holmes (1997), Lekagul & Round (1991), van Marle & Voous (1988), Medway & Wells (1970, 1976), Nash, S.V. & Nash (1985a, 1987b, 1988), Parrott & Andrew (1996), Rajathurai (1996), Robson (2000), Sheldon *et al.* (2001), Smythies (1986), Smythies & Davison (1999), Stattersfield & Capper (2000), Wilkinson, Dutton & Sheldon (1991), Wilkinson, Dutton, Sheldon, Darjono & Noor (1991).

## 133. Sulawesi Babbler

### *Trichastoma celebensis*

**French:** Akalat des Célèbes **German:** Weißkehl-Maustimalie **Spanish:** Tordina de Célebes  
**Other common names:** Celebes/Strickland's Babbler

**Taxonomy.** *Trichastoma* [sic] *celebensis* Strickland, 1849, Sulawesi.

Geographical variation partly clinal; proposed races *connectens*, from NC Sulawesi, and *improbatum* (of which *sordidum* is a synonym), from SE, considered to represent part of this cline, and therefore merged with *rufoscapulum*. Four subspecies recognized.

#### Subspecies and Distribution.

*T. c. celebensis* Strickland, 1849 – N Sulawesi (including islands of Manterawu, Bangka and Lembeh).  
*T. c. togianense* (Voous, 1952) – Togian Is (N Sulawesi).  
*T. c. rufoscapulum* (Stresemann, 1931) – C & SE Sulawesi, including Butung I.  
*T. c. finschi* Walden, 1876 – SW Sulawesi.

**Descriptive notes.** 15–5 cm. Smallish, relatively featureless babbler with strong bill and thin malar whisker, strikingly but mostly clinally varied in coloration. Nominate race has crown, nape and neck side dusky dark brown, upperparts slightly paler, upperwing and tail strongly fringed chestnut; lores, ear-coverts and cheek dusky ash-brown, ear-coverts with very fine buff shaft streaks, malar line darker, dusky grey; chin and throat silky white, breast (and especially breast side) soft grey, middle to lower belly silky white, flanks, thighs and vent pale brownish-ochre; iris brown; upper mandible black, lower mandible grey to pale grey; legs

pale grey-brown to brown. Sexes similar. Juvenile is like adult, possibly more saturated above and on lower flanks, but situation uncertain (report of dusky spotting on chest mistaken). Race *rufoscapulum* has pale brownish-ochre on malar line, breast and breast side; *togianense* is whiter below, breast, flanks and vent with slight warm buff wash; *finschi* lacks chestnut in wings and tail, and has entire underside ochrous-buff, palest on chin and throat and on mid-belly, darkest and brown-tinged on sides. **Voice.** Main song consists of short variable phrases of liquid fluty melancholy whistles, including “duwi’ wuwu’ wuei” (0.8 seconds), “tuwe-wi” (0.4 seconds), “tuu-tleé-pu-wiu” (1 second), in each phrase first note usually descending and last note upslurred; sometimes presumed female duets by answering phrases with insistent, high-pitched, nasal downslurred whistle, “kiew, kiew, kiew...”, given 2–10 times at 2 notes per second. Call by singing bird in excitement a bubbling “wuwuwuwuweweei”; female has continuous twittering “tededu tededu tededu...” during courtship display; rapid scolding “kshkshkshkshksh...”, varying in pitch and tempo; also heard.

**Habitat.** Primary broadleaf evergreen forest, selectively logged and disturbed primary forest, forest on ultrabasic rock, secondary woodland, wooded savanna, forest edge, scrub, thickets, coconut groves, cultivated areas with settlements, and sago swamps; lowlands to 1900 m, but perhaps mainly below 1000 m. In one study, most abundant in forest gardens and next most numerous in logged forest and natural forest, but abundance greater in more forested area overall than in more deforested one.

**Food and Feeding.** Presumably invertebrates. Forages close to or on ground, with mouse-like runs, on fallen trees and in dense scrub; has been observed also to call from canopy, at c. 13 m. **Shy.**  
**Breeding.** Apr–Dec. Nest a cup of dead leaves and grass blades, placed 0.3–0.5 m above ground. Clutch 2 eggs, greenish-white with reddish markings, likened to those of Spotted Flycatcher (*Muscicapa striata*). No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common and widespread, especially at lower elevations. Very common in all habitats at Gunung Ambang Nature Reserve, commonly heard (if rarely seen) in Manembonembo Nature Reserve and present in Panua Nature Reserve, in N Sulawesi; common in Bogani Nani Wartabone (Dumoga Bone) National Park, in N Sulawesi, common, at least locally, in Lore Lindu National Park, in C Sulawesi, and present in Rawa Aopa Watumohai National Park, in SE Sulawesi.

**Bibliography.** Bororing *et al.* (2000), Coates & Bishop (1997), Holmes & Wood (1980), Indrawan *et al.* (2006), Riley & Mole (2001), Riley *et al.* (2003), Rozendaal & Dekker (1989), Stresemann & Heinrich (1940b), Waltert *et al.* (2005), Wardill *et al.* (1999), White & Bruce (1986).

## 134. Ferruginous Babbler

### *Trichastoma bicolor*

**French:** Akalat ferrugineux **German:** Weißwangen-Maustimalie **Spanish:** Tordina Bicolor

**Taxonomy.** *Brachypteryx bicolor* Lesson, 1839, Sumatra.

Monotypic.

**Distribution.** Extreme S Myanmar (extreme S Tenasserim), S Thailand, Peninsular Malaysia, Sumatra and Borneo.

**Descriptive notes.** 16.5–18 cm. Smallish babbler, rufous-brown above and creamy below, with brighter rufous tail and rather long hook-tipped bill. Crown is pale dull rufous, with greyish-buff lores and vague supercilium, buffy-brown ear-coverts; mantle to rump and upperwing-coverts dull rufous-brown, wing fringed dull rufous, tail brighter rufous; underparts buffy whitish or creamy white, breast with slightly darker shading, somewhat variable individually; iris pale brown, sometimes reddish-brown, rarely red; upper mandible pale brown, lower mandible paler, flesh or greyish, sometimes slightly yellow at base; legs flesh-

brown. Sexes similar. Juvenile is brighter and warmer above than adult, with mantle and crown almost as bright as tail. **Voice.** Sings with repeated loud, clear, rather sharp “u-wit” or “u-wee” (second note higher); also variable low jolly phrases, e.g. “wit wi-ti-tu-tu”. Calls are low, harsh, dry, rasping sounds and sharp, explosive “wit” notes.

**Habitat.** Closed-canopy lowland evergreen mixed dipterocarp forest, selectively logged forest, upland heath forest, old rubber plantations, older *Albizia* plantations adjacent to forest, scrub left by shifting agriculture; also swamp-forest and locally in mangroves in Sumatra; commonest in primary forest in Sumatra. Below 700 m in SE Asia; below 600 m in Sumatra, above 920 m in Borneo (Sarawak).

**Food and Feeding.** Ants (Formicidae) and other insects. Found in pairs or in small loose parties of 4–5 individuals. Usually in lower to middle storey of forest; general foraging height 1–2.5 m, sometimes up to 10 m. Forages mainly by gleaning foliage.

**Breeding.** Apr–Jul in SE Asia and Feb–Sept in N Borneo (Sabah). Nest described as a small untidy open cup, made externally of dead bamboo or other leaves, internally of strips of palm leaves, dead

On following pages: 135. Bagobo Babbler (*Leonardina woodi*); 136. Rusty-headed Babbler (*Rohsonius rabori*); 137. Grey-banded Babbler (*Rohsonius sorsogonensis*); 138. Striped Wren-babbler (*Kenopia striata*); 139. Streaked Ground-babbler (*Ptilocheila mindanensis*); 140. Palawan Ground-babbler (*Ptilocheila falcata*); 141. Bornean Ground-babbler (*Ptilocheila leucogrammica*); 142. Marbled Wren-babbler (*Turdinus marmoratus*); 143. Large Wren-babbler (*Turdinus macrodactylus*); 144. Black-throated Wren-babbler (*Turdinus atrigularis*); 145. Rusty-breasted Wren-babbler (*Turdinus rufipectus*); 146. Limestone Wren-babbler (*Gypsophila crispifrons*); 147. Mountain Wren-babbler (*Napothera crassa*); 148. Streaked Wren-babbler (*Napothera brevicaudata*); 149. Eyebrowed Wren-babbler (*Napothera epilepidota*).

leaf stalks and fine twigs, placed in depression in bank, rattan, or pandan-like or ginger-like plant, 0.2–0.75 m above ground. Clutch 2 eggs, pale buffish-white with grey and pinkish-grey spots and flecks and chestnut blotches and squiggles, or whitish with reddish-brown mottling, or pink with red-orange spots and marks. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally fairly common to common in continental part of range, including Iaman Negara National Park, in Peninsular Malaysia. Local and moderately common throughout Borneo, and judged common in Sabah, including Danum Valley Conservation Area; present in Similajau National Park (Sarawak), and uncommon in Tanjung Puting National Park (S Kalimantan). Present in Gunung Leuser, Bukit Tigapuluh (common to fairly common) and Way Kambas (frequent) National Parks, in Sumatra; recorded from the now destroyed Padang-Sugihan Wildlife Reserve, in S Sumatra.

## Genus *LEONARDINA* Mearns, 1905

### 135. Bagobo Babbler

#### *Leonardina woodi*

**French:** Akalat de Wood    **German:** Mindanaomaustimalie    **Spanish:** Tordina de Mindanao

**Taxonomy.** *Leonardina woodi* Mearns, 1905, Todaya, 4000 feet [c. 1220 m], Mount Apo, Mindanao, Philippines.

Original genus name *Leonardia*, but that name was invalid, as preoccupied. Genus often merged with *Trichastoma* or with *Malacocincla*, but differs from both in its longer tarsus, shorter toes, rounded (rather than oval) nostril, thinner bill, proportionately longer tail, and very different song. Specimen from Mt Puting Bato (E Mindanao) distinctive, and likely to be described as a race. Currently treated as monotypic.

**Distribution.** Mindanao, in S Philippine Is.

**Descriptive notes.** 20 cm. Medium-sized, highly secretive ground-dwelling babbler, dark brown above and grey below, with white throat, long graduated tail, rather long legs. Crown and upperparts are dark chestnut-brown, feathers of rump long and soft with concealed white spots, upperwing and tail with slight rufescent wash; lores, cheek and ear-coverts grey, dark moustachial line passing under ear-coverts to neck side, submoustachial area grey and adjoining grey of underparts, except for white chin and throat and ochre-tinged flanks (some flank feathers having concealed white spots), olive-brown vent; iris reddish-brown; bill

black; legs blue-grey. Sexes similar. Juvenile apparently undescribed. **VOICE.** Song an extremely high-pitched, insect-like tinkling, reportedly in series of 4 or more notes, "seeeeeep seep seep", repeated every 4–5 seconds, but can be more or less continuous strophe, without obvious pauses, consisting of many more elided notes.

**Habitat.** Primary broadleaf evergreen and montane evergreen forest and edge, ridgetop forest and transition (lowland–montane) forest, at 500–2030 m.

**Food and Feeding.** Invertebrates, although specimens have been snared in rat traps baited with meat. Stays close to or on forest floor, hopping and walking.

**Breeding.** Birds in breeding condition in Feb, Apr and May. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Mindanao and the Eastern Visayas EBA. Formerly considered Vulnerable. Originally assumed to be very rare, but is mainly just elusive. Fieldwork involving snap-traps for small ground mammals and mist-nets for birds has yielded evidence that this species is common in areas surveyed; is therefore probably common on all higher mountains of Mindanao.

**Bibliography.** Delacour & Mayr (1946), Dickinson *et al.* (1991), Hachisuka (1934, 1835), Kennedy *et al.* (2000), McGregor (1909), Mearns (1905), duPont (1971), Rand (1950), Salomonsen (1952), Scharringa & Wassink (1990), *Fieldiana* (1909).

## Genus *ROBSONIUS* Collar, 2006

### 136. Rusty-headed Babbler

#### *Robsonius rabori*

**French:** Turdinule de Luzon    **German:** Rostgesichtimalie    **Spanish:** Ratina de Rabor  
**Other common names:** Rabor's/Rusty-faced/Luzon Wren-babbler

**Taxonomy.** *Napothera rabori* Rand, 1960, Tabbug, Pagudpud, Ilocos Norte, Luzon, Philippines. Previously placed in genus *Napothera*. Formerly regarded as conspecific with *R. sorsogonensis*. Monotypic.

**Distribution.** NE Luzon, in Philippine Is.

**Descriptive notes.** 20–22 cm; 48 g. Rather long-billed and long-legged ground-haunting babbler, brownish above with dull rusty-chestnut head, grey below with black markings and white streaks, and bold white spots on wings. Crown is rusty rufous with narrow black scales, shading to rufescent-olive upperparts with larger blackish scaling; plainer and rustier on very fluffily lower upperparts

brown, vent dark rufescent brown; iris hazel to brown; upper mandible dark horn-brown, lower mandible greyish-pearl; legs pearly brownish-horn. Sexes similar. Juvenile is dull chestnut-brown above, with two rows of pale wing spots, dull rufous-chestnut supercilium and ear-coverts, dull greyish-chestnut below, pale greyish-brown throat and continuous white margin to elongate flank feathering. **VOICE.** Song a variable, extremely high, wispy, slurred, insect-like "tsui-tsui-sui" or "tsui-tsui-sui-ee", rising at end, lasting 1.7–1.9 seconds, and repeated every 7–9 seconds (or less when excited); similar version also given with short introductory note, "tit-tsui-tsui-sui-ee", lasting 2.2–2.5 seconds, or sometimes "twit-tweet" or "tsui-tsui-sui-sui". Calls as yet undescribed.

**Habitat.** Lowland forest and second growth, from sea-level to 1000 m; one juvenile found by small pool in meadow near edge of secondary forest.

**Food and Feeding.** No information on diet; presumably invertebrates. Walks slowly across forest floor; also hops, and often cocks tail. Flips over leaves and wood debris in search of food.

**Breeding.** Juveniles in May. No other information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. When treated as conspecific with *R. sorsogonensis* listed as Near-threatened; formerly considered Vulnerable. Restricted-range species: present in Luzon EBA. Status difficult to determine owing to secretive habits. Considered uncommon. Tape playback indicates that it is more common than is implied by the rate at which it is encountered in the field. Forest destruction within its elevational range extensive, however, and populations must be declining and disappearing. Present in the Northern Sierra Madre Natural Park.

**Bibliography.** Anon. (2006d), Butchart & Stattersfield (2004), Collar (2006), Collar *et al.* (2001), Dickinson *et al.* (1991), Goodman & Gonzales (1990), Kennedy *et al.* (2000), duPont (1971), Poulsen (1995), Rand (1960), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

### 137. Grey-banded Babbler

#### *Robsonius sorsogonensis*

**French:** Turdinule du Sorsogon    **German:** Braungesichtimalie    **Spanish:** Ratina de Rand  
**Other common names:** Luzon/Sorsogon Wren-babbler

**Taxonomy.** *Napothera sorsogonensis* Rand and Rabor, 1967, Mount Bulusan, San Roque, Bulusan, Sorsogon Province, southern Luzon, Philippines.

Previously placed in genus *Napothera*. Formerly regarded as conspecific with *R. rabori*. Two subspecies recognized.

**Subspecies and Distribution.**

*R. s. mesoluzonicus* duPont, 1971 – C Luzon, in N Philippine Is.

*R. s. sorsogonensis* Rand & Rabor, 1967 – S Luzon and Catanduanes.

**Descriptive notes.** 20–22 cm; 57–65 g. Nominate race has forehead greyish-olive, shading on crown to olive, all with faint dark scales; mantle and upper back olive with faint narrow dark scales, becoming uniform brown on lower back, paler on rump, where white tips of feathers form semi-concealed bar, uppertail-coverts dark rufescent brown, tail dark brown; greater and median upperwing-coverts black, broadly fringed brown and tipped white, rest of upperwing-coverts greyish olive-brown, a few near bend of wing tipped white, primary coverts black with white tips, flight-feathers broadly edged brown, with bold white tips on

outer two and indistinct tip on third; lores and narrow supercilium to above eye white, cheek and ear-coverts grey, finely streaked white, submoustachial stripe white, narrow malar streak blackish; chin to upper breast white, neck and breast sides and middle to lower breast grey, belly white, long fluffy feathering on flanks dull rusty brown, undertail-coverts dark red-brown; iris brown; bill blackish-brown, basal half of lower mandible grey; legs light brown. Differs from similar *R. rabori* in having crown much less rusty, head side greyish with white flecks, chin to upper breast white, grey breastband shading to white belly, much less dark scaling above. Sexes similar. Juvenile has buffier throat and cheeks with less obvious dark tips on submoustachial area, weakly developed grey breastband, all-chestnut belly and flanks, obscured (grey-buff) tips of wing-coverts and outer primaries, pale lower mandible. Race *mesoluzonicus* has crown, hindneck and upperparts more rufescent and with somewhat bolder black feather margins than nominate, grey breastband broader, flanks darker. **VOICE.** Song a very high, thin, high-pitched "tit-tsui-tsui-sui-sui" (third and fourth notes higher, fourth rising towards end), also "tsui-tsui-sui-sui", "tsui-tsui-sui-sui", "tsui-tsui-sui-sui" or "tit-tsui-sui-sui", lasting 1.2–1.9 seconds and repeated every 2–7 seconds; similar in pitch and quality to that of *R. rabori*, but apparently somewhat shorter and simpler in structure. Calls as yet undescribed.

**Habitat.** Broadleaf evergreen forest, forest edge, secondary growth, vicinity of limestone rocks and outcrops, among bamboo and moss-covered rocks and boulders; lowlands to 1000 m.

**Food and Feeding.** Stomach of one specimen held insects; presumably many types of invertebrate taken. Forages on ground, walking slowly across forest floor, also hops; fans and cocks tail often at 30°, exceptionally higher (60°). Searches for food items by flipping over leaves and wood debris.

**Breeding.** Feb–Aug. Nest a large ball with large front entrance, placed 0.6–0.75 m above ground in rattan, resembles that of a pitta (*Pitta*). Clutch 2 eggs, white with reddish-brown speckles; nestlings fed by both sexes. No other information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. When treated as conspecific with *R. rabori* listed as Near-threatened; formerly considered Vulnerable. Restricted-range species: present in Luzon EBA. Sta-

tus difficult to determine owing to secretive habits. Considered uncommon. As with *R. rabori*, numbers may be higher than is suggested by field observations, although habitat loss within its range has been, and continues to be, extensive. Present in Quezon and Mount Isarog National Parks.

**Bibliography.** Collar (2006, 2007), Collar *et al.* (2001), Dickinson *et al.* (1991), Harrap & Mitchell (1994), Kennedy *et al.* (2000), Lambert (1993), duPont (1971), Rand & Rabor (1967), de Roever (1990).

## Genus *KENOPIA* G. R. Gray, 1869

### 138. Striped Wren-babbler

#### *Kenopia striata*

**French:** Turdinule striée

**German:** Goldzügelimalie

**Spanish:** Ratina Estriada

**Taxonomy.** *Timalia*, *striata* Blyth, 1842, "Singapore".  
Monotypic.

**Distribution.** Thailand, Peninsular Malaysia, Sumatra and Borneo.

**Descriptive notes.** 14–15 cm; 17–22 g. Bold-patterned small babbler with distinctive white face and underparts, and white streaks on brown mantle and neck. Crown and nape are black, with broad white streaks on central crown to nape, upperparts chestnut-brown, with broad white streaks on mantle and on slightly blackish neck side, smaller streaks on upperwing-coverts and back, with upperwing and tail rufescent brown; bristly erect loral feathers orange-buff, ear-coverts smudgy greyish, rest of face (supercilium, area around eye, cheek and submoustachial area) white and continuous with white of underparts, but breast

side scaled black and flanks streaked dull buffy ochre; iris brown to blackish; bill black to blue-black, base of lower mandible flesh-coloured; legs pale flesh. Sexes similar. Juvenile has crown brownish with narrow buffy-white streaks, reduced upperpart streaking, no neck-side streaking or breast-side scaling. **Voice.** Song a short clear monotone whistle, "chuiii", repeated every 1.5–2 seconds, with initial stutter; sometimes "chuiuu" or "chi-uuu", with very short space between notes. Calls include soft "pee-pee-pee", soft frog-like "churrh-churrh-churrh" and, when agitated, short twangy nasal notes.

**Habitat.** Broadleaf evergreen forest, lightly logged forest and upland heath forest; swampy areas reportedly favoured, but evidence needed. Up to 750 m in SE Asia, and to 200 m, locally 1500 m, in Sumatra; mostly to 610 m in Borneo, with single records from 1050 m and 1220 m.

**Food and Feeding.** Small thin insects reported. Usually singly or in pairs, sometimes in small parties. A terrestrial substrate-gleaner, foraging on or close to ground, among leaf litter, fallen logs etc.; some foliage-gleaning has apparently also been observed.

**Breeding.** May–Oct in SE Asia; bird in breeding condition in Feb and dependent young in May in N Borneo (Sabah). Nest an open cup, mainly of dead leaves, lined simply with blackish root-like material, placed up to 1 m above ground in palm-like understorey plant. Clutch 2 eggs, whitish, strongly but rather sparsely marked primarily with rufous-brown to reddish-brown spots and blotches. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Generally uncommon, occurring at fairly low density. Fairly common in Taman Negara National Park, in Peninsular Malaysia. Frequent in Borneo, although reportedly uncommon in Sabah, where fairly common in Danum Valley Conservation Area; relatively infrequent in Berau district forest (E Kalimantan), and present in Similajau National Park (Sarawak) and Kayan Mentarang National Park (E Kalimantan). Occurs in Gunung Leuser, Bukit Tigapuluh and Way Kambas (scarce) National Parks, in Sumatra. As a Sundanic lowland-forest species, it is highly susceptible to extensive forest destruction throughout its range, although its ability to survive in hill-slope and logged forest implies that it is not immediately at risk. Numbers decline, however, in response to fragmentation and logging of lowland-forest habitat.

**Bibliography.** Anon. (2006d), Buij *et al.* (2006), Butchart & Stattersfield (2004), Chasen (1939), Collar *et al.* (2001), Danielsen & Heegaard (1995), Duckworth & Kelsch (1988), Duckworth *et al.* (1997), Eames (2005), Gore (1968), Holmes (1996, 1997), Johns (1989), Lambert & Collar (2002), Lekagul & Round (1991), van Marle & Voous (1988), Medway & Wells (1976), Parrott & Andrew (1996), Robson (2000), Sharpe (1889), Sheldon *et al.* (2001), Stattersfield & Capper (2000), Thompson (1966), Wilkinson, Dutton & Sheldon (1991), Wilkinson, Dutton, Sheldon, Darjono & Noor (1991).

## Genus *PTILOCICHLA* Sharpe, 1877

### 139. Streaked Ground-babbler

#### *Ptilocichla mindanensis*

**French:** Turdinule des Philippines

**Spanish:** Ratina de Mindanao

**German:** Philippinenwollimalie

**Other common names:** Streaked/Striated Wren-babbler; Mindanao Ground-babbler (*mindanensis*)

**Taxonomy.** *Ptilopygia mindanensis* A. W. H. Blasius, 1890, Mindanao, Philippines.

Four subspecies recognized.

**Subspecies and Distribution.**

*P. m. minuta* Bourns & Worcester, 1894 – Samar and Leyte, in EC Philippine Is.

*P. m. fortichi* Rand & Rabor, 1957 – Bohol, in SC Philippines.

*P. m. mindanensis* (A. W. H. Blasius, 1890) – Mindanao, in S Philippines.

*P. m. basilanica* Steere, 1890 – Basilan, off W Mindanao.

**Descriptive notes.** 13–14 cm; 26–31 g. Distinctive smallish short-tailed ground-dwelling babbler, dark brown with white throat, long white stripes below. Nominative race has crown blackish-edged rufescent brown with pale shaft streaks, upperparts dull rufescent brown with vague pale shaft streaks, rump plain and more chestnut, upperwing and tail plain brown with slight rufescent tinge; lores whitish, bold white postocular supercilium, ear-coverts greyish-brown, submoustachial stripe black; chin and throat white, underparts dull ochrous-brown with long broad white stripes, narrower and fewer stripes on lower areas; iris variable, orange

to dark brown; bill blackish, paler base of lower mandible; legs brown to dark brown. Sexes similar. Juvenile apparently undescribed. Race *minuta* is smaller than nominate, with darker brown upperparts, bolder shaft streaks on back, and slightly darker breast; *fortichi* is like previous, but margins of crown and back feathers black, lower back and rump darker, and greater contrast between blackish-brown and white on underparts; *basilanica* has pale chestnut-brown upperparts with pale shaft streaks. **Voice.** Song on Bohol a spaced 8-note series, descending in pitch, with stressed notes, "hi hi hi hi hi 'hu hi hi hiéw", reminiscent of that of a *Cacomantis* cuckoo; on Mindanao song similar, "hi hi hi 'uu uu uu uu-u", with second song type consisting of 4–12 clear penetrating "hiúú" or "jhiéw" whistles, first syllable stressed but quieter, "hiúú-hiúú-hiúú-hiúú...", both types being recorded simultaneously. In alarm, calls with short spluttering notes stressed at start, "trrr'lt", "trrr'lt", "wh'rrp" and similar.

**Habitat.** Primary and logged forest; generally below 1000 m, but to 1400 m on Mt Kitanglad (Mindanao).

**Food and Feeding.** Presumably invertebrates. Found singly, in pairs or in small parties of up to four individuals. Forages in dense low vegetation near ground, or while walking on ground; turns over leaves.

**Breeding.** Jan–Aug. One nest was a small semi-domed cup, made of dead leaves, loosely lined with roots and small plant twigs, 0.3 m above ground and wedged among leaf-stalk bases of small spiny palm; contained 1 egg, bluish-tinged white, with mid-brown blotches and lines and underlying pale purple-brown clouds. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in Mindanao and the Eastern Visayas EBA. Considered to be generally uncommon in most of range, though fairly common in Rajah Sikatuna National Park, on Bohol. Previously classified as Near-threatened.

**Bibliography.** Blasius (1890b), Brooks *et al.* (1996), Delacour & Mayr (1946), Dickinson *et al.* (1991), Hachisuka (1935), Kennedy *et al.* (2000), McGregor (1909), Ogilvie-Grant (1897), duPont (1971), Rand & Rabor (1957, 1960), Robson & Davidson (1996), Stattersfield *et al.* (1998).

### 140. Palawan Ground-babbler

#### *Ptilocichla falcata*

**French:** Turdinule de Palawan

**German:** Palawanwollimalie

**Spanish:** Ratina de Palawan

**Other common names:** Falcated Ground-babbler/Wren-babbler/Babbler

**Taxonomy.** *Ptilocichla falcata* Sharpe, 1877, Puerto Princesa, Palawan, Philippines.  
Monotypic.

**Distribution.** Palawan and reportedly also Balabac, in W Philippines.

**Descriptive notes.** 19–20 cm. Medium-sized ground-babbler covered in remarkable long black-and-white stripes, with rusty patches on head; bill rather long and straight with hooked tip, tail proportionately longer than that of congeners. Body plumage above and below is loose and elongate, black with long whitish stripes; wing and tail mid-brown with chestnut wash, crown and hindneck chestnut-brown, forehead, frontal lores, supercilium and neck side light chestnut, basal lores and ear-coverts dark brown, broad submoustachial stripe white, narrow malar stripe blackish, chin and throat white; iris hazel to dark brown; bill

rather long and straight with hooked tip, blackish with dull horn base to lower mandible; legs dark brown to horn-brown. Sexes similar. Juvenile apparently undescribed. **Voice.** Song a loud, mournful, undulating, variable whistled couplet, not unlike that of *Napothera*, monotonously repeated, e.g. "hiuuu-huu'oo" (first note generally rising, second descending slightly), "hiuii-huu'oo", "huuii-hee'oo'oh" and the like, occasionally with single part of couplet only; also jumbled chattering versions when excited.

**Habitat.** Primary broadleaf evergreen forest, often in vicinity of streams, gulleys and ridgetops, also in bamboo forest at two sites; apparently not present in logged or secondary forest. Lowlands to at least 800 m.

**Food and Feeding.** Scorpions found in stomach of one specimen; insects and berries also recorded. Forages secretively on or near ground; walks, hops and scrambles around dense thickets and fallen trees.

**Breeding.** Jan; two birds with weakly developed gonads in Oct and Nov. Probably present on territory all year. No other information.

**Movements.** Resident.

**Status and Conservation.** VULNERABLE. Restricted-range species; present in Palawan EBA. Known from only ten sites on Palawan, of which only four involve post-1980 records. Formerly considered fairly common and even, at one site, abundant, but in recent years appears to have declined both in density and in number of locations. Logging of lowland forest evidently incompatible with this species' survival, and very little intact habitat now remains on the island. Present in St Paul's Subterranean River National Park, and also benefits from some protection in Iwahig Penal Colony. Formerly categorized as Endangered.

**Bibliography.** Anon. (2006d), Butchart & Stattersfield (2004), Collar, Andreev *et al.* (2001), Collar, Mallari & Tabaranza (1999), Dickinson *et al.* (1991), Hachisuka (1935), Kennedy *et al.* (2000), Lamberti (1993), McGregor (1909), duPont (1971), Sharpe (1877b), Sison (1983), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Whitehead (1890).

## 141. Bornean Ground-babbler

*Ptilocichla leucogrammica*

French: Turdinule de Bornéo German: Borneowollimalie Spanish: Ratina de Borneo  
Other common names: Bornean Wren-babbler

**Taxonomy.** [*Cacopitta*] *leucogrammica* Bonaparte, 1850, Pontianak, south-west Borneo. Monotypic.

**Distribution.** Borneo.

**Descriptive notes.** 15–16 cm; 37–42 g. Crown is dull olive-brown with vague blackish scaling, upperparts uniform chestnut-brown, more intensely chestnut on upperwing and very fluffy rump, tail blackish-chestnut; head side mottled and streaked; chin, submoustachial area and throat whitish with tiny black tips, with broken black malar line, breast to belly black with broad white round-ended stripes, all shading to dull ochreous-chestnut on lower flanks, thighs and vent; iris dark brown; upper mandible black, lower mandible pale grey; legs grey. Differs from similar *P. mindanensis* in larger size, much longer bill and neck, more

contrasting dark cap, more chestnut upperparts, shorter white stripes on black underparts. Sexes similar. Juvenile is less rufescent above than adult, crown lightly streaked. **Voice.** Song consists of 2 mournful, pure-tone whistles given reportedly in antiphonal duet by territorial pair from perch near ground, “doo-dee” or “doo-doo-dee”. Call a spluttering “churr” or “prrr”.

**Habitat.** Primary, secondary and sometimes recently logged lowland broadleaf evergreen dipterocarp forest, peatswamp-forest dominated by *Shorea alba*, and upland heath forest, at 40–600 m; recorded once in seven-year-old *Albizia* plantation. Found especially in gulleys and along dry creeks. Almost certainly intolerant of serious habitat degradation, as densities greatly reduced in logged forest compared with primary forest.

**Food and Feeding.** Small insects found in two stomachs. Forages in pairs and family parties on forest floor and among herb layer; probes under leaves, on dead logs and among rotting treefalls.

**Breeding.** Feb–Sept; birds in breeding condition in Jul, Aug and Oct in N Borneo (Sabah). Territories apparently held all year. Clutch 2 eggs. No other information.

**Movements.** Resident.

**Status and Conservation.** VULNERABLE. Rare and local. Highly sensitive to forest disturbance by logging, and disappears completely with forest clearance. Destruction and degradation of lowland forest in Borneo have led to loss of almost all primary areas in the past several decades; of 40 known sites for this species, only nine involve post-1980 records. This species is perhaps particularly disadvantaged because it is probably little able to disperse through inappropriate habitat, leading to highly isolated populations. Known from Danum Valley Conservation Area and Tabun Wildlife Reserve, in Sabah; Gunung Mulu, Batang Ai and Similajau National Parks and Samunsam Reserve, in Sarawak; Ulu Temburong National Park, in Brunei; and Kayan Mentarang, Kutai and Gunung Palung National Parks, in Kalimantan.

**Bibliography.** Anon. Genus *TURDINUS* Blyth, 1844

## 142. Marbled Wren-babbler

*Turdinus marmoratus*

French: Turdinule marbrée German: Marmortimalie Spanish: Ratina Jaspeada

**Taxonomy.** *Turdinus marmoratus* R. G. W. Ramsay, 1880, Padang Highlands, western Sumatra. Genus commonly merged into *Napothera*. Two subspecies recognized.

**Subspecies and Distribution.**

*T. m. grandior* Voous, 1949 – Peninsular Malaysia.

*T. m. marmoratus* R. G. W. Ramsay, 1880 – Sumatra.

**Descriptive notes.** 21–5 cm. Large, sturdy babbler with prominent scaling above and below. Has crown to back deep warm brown with blackish scaling, rump plainer, more chestnut-tinged and very fluffy, upperwing and tail dull rufescent brown; lores whitish, face (supercilium, cheek, ear-coverts) and neck side chestnut, chin and throat white, black scaling on lower throat; submoustachial area black with white flecks, adjoining black breast to belly with narrow white scaling, all becoming dull ochreous-chestnut on lower flanks, thighs and vent; iris chestnut; bill black; legs black, often with brownish tinge. Sexes similar. Juvenile

has rufous shaft streaks on head and mantle, broadening towards tips, underparts dark brownish-grey with slight rufous tips becoming buffier on belly, so that scaled pattern very indistinct. Race *grandior* is slightly larger than nominate. **Voice.** Sings with clear double or single whistle, “puuu-chiiiii”, “pyuuu-chiiiii” or “puuii-jhiiii”, with higher, somewhat rising first note and lower, buzzy second note, like *T. macrodactylus*. Also “puuu-chiiiii” and “uuuu-jhi” or single “puuii”.

**Habitat.** Lower montane broadleaf evergreen forest, at 610–1220 m in Peninsular Malaysia, 1000–2000 m in W Sumatra.

**Food and Feeding.** Insects, including beetles (Coleoptera) and grubs; sometimes fallen berries and small fruits. Forages on or near ground, in undergrowth, often in damp areas. Very shy and secretive.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Sumatra and Peninsular Malaysia EBA. Rare and local in Peninsular Malaysia. Present in Gunung Leuser and Kerinci Seblat National Parks, in Sumatra. Formerly considered Near-threatened.

**Bibliography.** Buij *et al.* (2006), Glenister (1951), Holmes (1996), MacKinnon & Philipps (1993), van Marle & Voous (1988), Medway & Wells (1976), Robinson (1928), Robinson & Kloss (1919b), Robson (2000), Stattersfield *et al.* (1998), Voous (1949).

## 143. Large Wren-babbler

*Turdinus macrodactylus*

French: Grande Turdinule German: Graubauchtimalie Spanish: Ratina Grande  
Other common names: Large-footed Wren-babbler

**Taxonomy.** *Malacopteron macrodactylum* Strickland, 1844, Malacca, Peninsular Malaysia.

Genus commonly merged into *Napothera*. Has been thought to form a superspecies with *T. atrigularis* and *T. rufipectus*. Three subspecies recognized.

**Subspecies and Distribution.**

*T. m. macrodactylus* (Strickland, 1844) – S Thailand and Peninsular Malaysia.

*T. m. beauforti* Voous, 1949 – Sumatra

*T. m. lepidopleurus* (Bonaparte, 1850) – Java.

**Descriptive notes.** 19 cm; 52–58 g. Fairly large, streaky brown babbler with white throat and greyish underparts. Nominative race has crown to back streaked light brown and black, becoming slightly paler, plainer, more rufescent brown on fluffy rump and uppertail-coverts; upperwing and tail brown, former fringed pale brown; lores whitish, with dense dark grey speckling on lower portion, greyish-blue bare skin around eye, more extensive behind eye, separated from crown by black line, ear-coverts blackish-brown, submoustachial area speckled whitish and brown; chin, throat and upper breast off-white with some brown flecking, bordered below by scrappy blackish-brown breastband (variable in strength and width), lower breast to belly brownish-grey with vague broad buffy-white streaks, more ochreous on flanks and tinged cinnamon on thighs and vent; iris brown; bill blackish-horn; legs brownish. Sexes similar. Juvenile has upperparts and wings paler and more rufous than adult, darker crown and ear-coverts, pale buff shaft streaks (but no pronounced dark scaling) on upperparts, rather uniform below, slightly rufescent, pale drab brown, with whiter throat and belly centre and indistinct darker breast markings. Race *beauforti* has less developed breastband than nominate, upperparts generally darker; *lepidopleurus* is notably darker above, with almost no breastband, darker grey mid-belly, browner flanks and vent. **Voice.** Song very variable. Usually consists of short loud clear whistled phrases, repeated every few seconds, e.g. “chuu-chreeh” or “chu-chiii”, or descending and then rising “phuu-wiii” or “u-wiii”; also, single “chuuu”, sometimes combined with coarser notes as e.g. “uuu-chorii” or “chuuu weeah-weeah”. May give longer series of rather slow notes, e.g. “wii-tu-tu-tu-tu” (first note higher) and “pu-chuu-chuu-chuu-chuu”. During duets, slow “pu-yu-yu...” is answered by “chuuu” or “chuuu-chii”. Longer song variants include “uuu-wi-wi-wi-wi-wriiu” (mid-section faster) and “pi-pi-pi-pi-pi-peeoo”, with slower last note.

**Habitat.** Broadleaf evergreen forest, selectively logged forest, bamboo forest, “rubber jungle”; favours thickets of rattan, salak palm, bamboo and gingers. Usually below 200 m in Thailand, but to 700 m in SE Asia generally; locally to 900 m in Java.

**Food and Feeding.** Invertebrates. Found singly, in pairs or small parties. Forages on or close to ground (but sings from higher perches, up to c. 5 m or more). Turns over leaves on ground in manner of a pitta (*Pitta*).

**Breeding.** Dec–Jul in SE Asia and Mar and Sept in W Java. Nest a large cup made of dead leaves, lined with thin layer of twigs, roots and hair, often surrounded by more leaves, placed 0.4–1 m above ground in middle of rattan, pandan or crown of spiny palm. Clutch 2 eggs, pale pinkish-white to pinkish-red with diffuse dark reddish-pink lines and spots, or red squiggly lines, or few scattered small dark reddish blotches. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Uncommon to fairly common in S Thailand and Peninsular Malaysia; extinct in Singapore. A Sundic lowland-forest species, thus highly susceptible to the extensive forest destruction throughout its range, although use of submontane forest implies that it is not immediately at risk. Numbers decline in response to fragmentation and logging of lowland-forest habitat. Fairly common in Khao Pra-Bang Kham Wildlife Sanctuary, in Thailand, and common in Taman Negara National Park, in Peninsular Malaysia. Present in Gunung Leuser and Bukit Tigapuluh National Parks, in Sumatra. Present in Ujung Kulon National Park, in W Java, and Alas Purwo and Baluran National Parks, in E Java. An unconfirmed record from Bali.

**Bibliography.** Anon. (2006d), Buij *et al.* (2006), Butchart & Stattersfield (2004), Chasen (1939), Collar *et al.* (2001), Danielsen & Heegaard (1995), Deignan (1963), Grantham (2000), Holmes (1996), Hoogerwerf (1971), Johns (1989), Lambert & Collar (2002), Lekagul & Round (1991), MacKinnon (1988), van Marle & Voous (1988), Medway & Wells (1976), O’Brien & Kinnaird (1996), Robson (2000), Sody (1956), Stattersfield & Capper (2000), Voous (1949).

## 144. Black-throated Wren-babbler

*Turdinus atrigularis*

French: Turdinule à gorge noire German: Fahlbauchtimalie Spanish: Ratina Golinegra

**Taxonomy.** [*Cacopitta*] *atrigularis* Bonaparte, 1850, Borneo.

Genus commonly merged into *Napothera*. Has been thought to form a superspecies with *T. macrodactylus* and *T. rufipectus*. Monotypic.

**Distribution.** Borneo.

**Descriptive notes.** 18 cm; 61–71.5 g. Fairly large, dark, streaky babbler, with black face, throat and breast. Crown is dull buffy brown with narrow black scaling, upperparts brighter warm buffy ochre with heavy black streaking, uppertail-coverts dull rusty, upperwing and tail dark brown, former with paler and more rusty-brown tinges; lores and submoustachial stripe pale buff, ear-coverts, chin, submoustachial area, throat and upper breast black, mid-breast to belly pale buff with black scales, latter fading on plain buff lower belly, and becoming bright rusty on lower flanks; thighs and vent; iris

reddish-brown to dark brown, bare skin behind eye pale blue; bill black, lower mandible grey, or horn at base; legs horn to dull pinkish-brown. Sexes similar. Juvenile more reddish-brown above, rusty buff below, with heavy blackish streaking and scaling on throat, breast and flanks. Voice. Song, in duet by pair, a series of 8–10 long, loud, plaintive, slightly downslurred whistles, also a long series of up to 42 clear bell-like notes, starting more slowly, then delivered quite quickly, notes including “iuuh”, “iiew”, “iyuh” and “yuuh”, e.g. “iiew iiew iiew-iiew-iiew-iiew-iiew-iiew-iiew-iiew-iiew-iiew...”. In duet, one bird gives a series of this song type while other

adds slightly descending “iuuh-iuh-iuh... iuuh-uh-uh”. Calls include “we-ah, we-ah, we-ah”, very deep and gruff, recalling *Kenopia striata*, and (possibly the same) a rather nasal, coarse “krav, krav”. **Habitat.** Mainly primary lowland broadleaf evergreen forest, especially on river terraces, old secondary forest, logged forest (where much rarer), but extends into montane forest; generally in lowlands and lower slopes to 500 m, with individual records at 1150 m in Sabah and 1220 m in Sarawak. **Food and Feeding.** No information on diet; presumably small invertebrates and some vegetable matter. Mainly terrestrial, searching leaf litter and flicking leaves aside with bill; also creeps about beneath tree roots and clings low down to bark of trees, not using tail for support, and investigates crevices by probing with bill. In groups of up to seven individuals.

**Breeding.** Dec–May in Sabah. Probable nest in Nov (Sabah) was a big untidy cup of dead leaves with finer lining, placed less than 0.5 m up in diverging bases of ginger fronds; contained two young. Egg laid during capture was white with rufous splotches. No other information. **Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Uncommon in Sabah, where present in Danum Valley Conservation Area. Forest destruction in the Sundaic lowlands of Indonesian Borneo has been so extensive that it was predicted in 2000 that all primary formations would have disappeared by the year 2010, and situation is little different in Malaysian Borneo; the species’ preference for submontane forests, however, implies that it is not immediately at risk.

**Bibliography.** Anon. (2006d), Buichart & Stattersfield (2004), Chasen & Kloss (1930), Collar *et al.* (2001), Holmes & Burton (1987), MacKinnon & Philipps (1993), Sharpe (1889), Sheldon *et al.* (2001), Smythies & Davison (1999), Stattersfield & Capper (2000), Voous (1949, 1961).

## 145. Rusty-breasted Wren-babbler

### *Turdinus rufipectus*

**French:** Turdinule de Sumatra **German:** Kastanienbauchtimalie **Spanish:** Ratina Pechirrufa  
**Other common names:** Rufous-chested Wren-babbler, Sumatran (Large) Wren-babbler

**Taxonomy.** *Turdinus rufipectus* Salvadori, 1879, Mount Singgalang, western Sumatra. Genus commonly merged into *Napothera*. Has been thought to form a superspecies with *T. macrodactylus* and *T. atrigularis*. Monotypic. **Distribution.** Sumatra.

**Descriptive notes.** 18–19 cm. Mid-sized babbler, scaled dark brown above, dull rusty with vague dark scales and pale streaks below, throat whitish. Crown, neck side and upperparts are warm buffy brown with broad dark brown scaling, upperwing and tail blackish-brown; most of head side with bluish-grey bare skin, ear-coverts grey-brown with dark brown markings; chin and upper throat whitish with blackish peppering, underparts rusty tan with pale shaft streaks and very narrow brown scaling, buffier on mid-belly and darker, blackish-ochre on lower flanks, thighs and vent; iris red, chestnut, brown or chocolate, bluish-grey orbital

skin (particularly over and behind eye); bill black; legs dark brownish. Sexes similar. Juvenile apparently undescribed. Voice. Song a clear piping “hi-hi-hi-hi-hi-huuh” or “ip’ip’ip’ip’ip’ip’uuuh” (with c, 4–6 short notes), lasting 1.2–1.6 seconds, and repeated every 3–6 seconds. In duet, one bird utters almost continuous “ip’ip’ip’ip’ip’ip’...” while second gives varied, undulating “hu-wip ii”, either slow and spaced or speeded-up to “hu-wip’ee”. Calls apparently undocumented. **Habitat.** Primary montane broadleaf evergreen forest, and dense roadside vegetation in conifer plantations, at 900–2500 m.

**Food and Feeding.** Insects, small snails. Forages on ground among leaf litter, and just above ground level.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in Sumatra and Peninsular Malaysia EBA. Locally common throughout mountain ranges of Sumatra, and found to be very common in N, near Brestagi; present in Gunung Leuser and Kerinci Seblat National Parks, and locally common at latter. Apparently a low-density species even in good habitat, and probably one that reacts very unfavourably to habitat modification and fragmentation; consequently, a species that is informally of conservation concern.

**Bibliography.** Buij *et al.* (2006), Chasen & Hoogerwerf (1941), Holmes (1996), MacKinnon & Philipps (1993), van Marle & Voous (1988), Meyer de Schauensee & Ripley (1940a), Robinson & Kloss (1924b), Stattersfield *et al.* (1998), Tobias (1995), Voous (1949).

## Genus GYPSOPHILA Oates, 1883

### 146. Limestone Wren-babbler

#### *Gypsophila crispifrons*

**French:** Turdinule des rochers **German:** Kalksteintimalie **Spanish:** Ratina Roquera

**Taxonomy.** *Turdinus crispifrons* Blyth, 1855, Mulayit Taung Tenasserim, Myanmar. Commonly placed in genus *Napothera*. Three subspecies recognized.

**Subspecies and Distribution.**

*G. c. annamensis* (Delacour & Jabouille, 1928) – S China (S Yunnan), N Laos and N Vietnam (Tonkin, N Annam).

*G. c. crispifrons* (Blyth, 1855) – SE Myanmar (including N Tenasserim) and NW & W Thailand.

*G. c. calcicola* (Deignan, 1939) – SW part of NE Thailand.

**Descriptive notes.** 15–16 cm. Rather long-billed and long-tailed mid-sized, dark greyish-brown babbler with dark scales above, whitish streaky throat and mid-belly. Nominat race has crown to back greyish-tinged dark brown with neat narrow black scaling, fluffy rump greyish dark brown, upperwing and tail dark brown, tiny whitish tips on tertials; lores and supercilium vaguely greyish, ear-coverts grey-streaked dark brown, submoustachial area spotted dark brown and whitish; chin to belly whitish with broad grey-brown streaks, sparse on chin and throat, thick on breast and belly and merging with all grey-brown flanks, thighs

and vent, latter ochrous; ■ white-faced and white-throated morph (or partial albino), with white variable in extent and symmetry, occurs in (at least) Tenasserim; iris reddish-brown; bill dark horn, greyer lower mandible; legs greyish-brown. Sexes similar. Juvenile apparently undescribed. Race *calcicola* has thin pale shaft streaks on upperparts, rufescent-brown underparts; *annamensis* has slightly paler, greyer crown and mantle with white shaft streaks, greyer lower breast and mid-belly. Voice. Song a loud rapid faltering series of unevenly pitched harsh slurred notes, starting very abruptly, roughly “chitu-wi-witchuwitchiwitchiwitchiwitchiwitchiu” or slower “titu-titu-titu-titu-titu...”; bouts last 4–30 seconds and are usually repeated after long intervals. Alarm calls are harsh, scolding rattles, “chrrr-chrrr-chrrr...” and “chrrrrow-chrrrrow...”, etc.

**Habitat.** Evergreen and mixed deciduous forest and scrub in limestone hill country, usually with boulders and steep crags in shady, moist areas. At up to 2135 m in Myanmar, below 915 m in Thailand and SE Asia generally, and 300–400 m in Vietnam; below 915 m in China.

**Food and Feeding.** Insects and seeds. Found in pairs or in small parties of up to six individuals (possibly family parties), moving around rocks and tangled vegetation. In Laos, seen to forage around small temple by limestone cliff, entering porches and seemingly indifferent to close passage of monks; yet can be secretive.

**Breeding.** Aug–Sept. Nest a roofed cup or dome with circular entrance, made of dried twigs, roots and other plant material, neatly woven, lined with fine plant material, placed in rock crevice, in one case 10 m from base of outcrop. Clutch 2–5 eggs, white, mottled and spotted purplish-brown, reddish-brown, blackish and mauve. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally locally common across range. Local and uncommon in China. Seemingly much rarer than its habitat in Laos, with very few records. Present in Ba Be National Park and common in Cuc Phuong National Park, in Vietnam.

**Bibliography.** Cheng Tsohsin (1987), David-Beaulieu (1944), Deignan (1963), Delacour (1929), Delacour & Jabouille (1931a), Duckworth, Davidson & Timmins (1999), Duckworth, Tizard *et al.* (1998), Eames *et al.* (2001), Hill (2000), Hume & Davison (1878), Lekagul & Round (1991), Meyer de Schauensee (1984), Robson (2000), Robson *et al.* (1989), Smythies (1986), Williamson (1945).

## Genus NAPOTHERA G. R. Gray, 1842

### 147. Mountain Wren-babbler

#### *Napothera crassa*

**French:** Turdinule des montagnes **German:** Blasskehlimalie **Spanish:** Ratina Montana

**Taxonomy.** *Corythocichla crassa* Sharpe, 1888, Kinabalu, north Borneo.

Has been thought to form a superspecies, and possibly to be conspecific, with *N. brevicaudata*. Monotypic.

**Distribution.** Borneo.

**Descriptive notes.** 14 cm. Pale-streaked dark chunky small babbler with dull white throat and dull rufous belly, bristly forecrown feathers projecting forwards. Has crown to lower back blackish with pale buff shaft streaks and dull ochre inner webs, latter becoming dominant posteriorly; dense, fluffy and elongate rump feathers dark brown, upperwing and tail dark brown; lores and supercilium dull whitish-grey (but dark brown spot in front of eye), extending over pale-streaked brown ear-coverts; dull buffy-grey submoustachial area, vague narrow dark malar line; chin to upper breast whitish, shading through vague pale

grey on mid-breast to greyish-ochre with pale rufous streaking on lower breast and to increasingly browner and darker flanks and dark brown vent; iris reddish-brown to dark brown; upper mandible blackish, lower mandible paler with greyish base; legs horn to dark brown. Sexes similar. Juvenile apparently undescribed. Voice. Song a clear, rather shrill and thin steady piping, e.g. “hi-hi-hi-hi-hi”, “hi-hi-hi-hi-hi” or “hi-hi-hi-hi-hi-hi-hi-hi-hi” (notes 3–5 undulating), lasting 0.9–1 second and repeated every 1–3 seconds; sometimes shortened to 2 notes when excited. In song duet, one bird gives this song type, while other repeatedly utters descending “hii-hii-hii”. Calls with quick, stressed “whit” and “whik” notes, “whit” “chrrh”, etc.

**Habitat.** Broadleaf evergreen forest, reportedly preferring dense dark forest where terrain broken up by steep slopes and rocky ravines, and often in densely vegetated banks and beds of small streams, also forest edge and low bamboo growth; at 900–2900 m.

**Food and Feeding.** Insects, including grasshoppers (Orthoptera), also tiny snails. Found in pairs or in small (usually family) parties of 4–5 individuals, sometimes up to ten. Forages in low vegeta-

tion, but often at some height above ground. Rather skulking, but not shy, and sometimes remarkably tame.

**Breeding** Feb–Aug in Sabah. Nest described as a cup made of grasses, placed in moss-covered bank by forest trail. Clutch 2 eggs, white, blotched and streaked with purplish-red, or reddish-buff with brown blotches. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in Bornean Mountains EBA. Uncommon in Sabah, but common in Mount Kinabalu National Park. Common in Gunung Ntut Nature Reserve, in W Kalimantan.

**Bibliography.** Banks (1937a, 1937b), Davison (1992), MacKinnon & Phillips (1993), Priemé & Heegaard (1988), Sharpe (1889), Sheldon *et al.* (2001), Smythies & Davison (1999), Stattersfield *et al.* (1998).

## 148. Streaked Wren-babbler

### *Napothera brevicaudata*

**French:** Turdinule à queue courte **German:** Stutzschwanztimalie **Spanish:** Ratina Colicorta  
**Other common names:** Short-tailed/Streak-throated Wren-babbler

**Taxonomy.** [*Turdinus*], *brevicaudatus* Blyth, 1855, Mulayit Taung, Amherst District, Tenasserim, Myanmar.

Has been thought to form a superspecies, and possibly to be conspecific, with *N. crassa*. Races remarkably diverse within rather narrow phenotypic confines, falling into two geographically unassorted groups, one with dull rufous underparts and clearly marked dark and white throat streaks (nominate, *striata*, *rufiventer*), and the other with browner underparts and less contrasting, vaguer streaks (*stevensi*, *proxima*, *griseigularis*); *leucosticta* notably distinctive. Further investigation of species limits required. Birds in N & E Myanmar and W Yunnan (China) sometimes separated as race *venningi*, supposedly larger and more rufous, but fall within range of variation of nominate. Racial identity of birds in NW Laos uncertain, conditionally included in nominate. Seven subspecies recognized.

**Subspecies and Distribution.**

*N. b. striata* (Walden, 1871) – NE India S of R Brahmaputra (including SE Arunachal Pradesh) and NW Myanmar.

*N. b. brevicaudata* (Blyth, 1855) – S China (W Yunnan), NE, E & SE Myanmar (including N Tenasserim), NW, W & N Thailand, and NW Laos.

*N. b. stevensi* (Kinnear, 1925) – S China (SE Yunnan E to W Guangxi), NE & C Laos and N Vietnam (Tonkin, N Annam).

*N. b. proxima* Delacour, 1930 – S Laos and C Vietnam (C Annam).

*N. b. griseigularis* (Delacour & Jabouille, 1928) – SE Thailand and SW Cambodia.

*N. b. rufiventer* (Delacour, 1927) – S Annam (Vietnam).

*N. b. leucosticta* (Sharpe, 1887) – S Thailand and Peninsular Malaysia, including Tioman I.

**Descriptive notes.** 12–17 cm. Smallish, rather short-tailed brown babbler with heavy blackish streaking above, dull below with streaked whitish throat and breast. Nominative race has crown and upperparts ochrous-brown, blackish edges of feathers forming broad long black lines, fluffy rump unpatterned dark ochrous-brown, upperwing dark brown with warm olive-brown fringes and tiny whitish tips (wing spots) on some greater coverts and most flight-feathers, tail dark chestnut-brown; face (lores, supercilium, ear-coverts, cheek and submoustachial area) dull greyish with buff and brown mottling; chin to upper breast greyish-white

with thick, soft-edged but neat olive-brown streaks, shading into dull rufous breast side and breast, these shading to streaky dull rufous on lower flanks, belly, thighs and vent; iris red, brown or chocolate-red; bill dark brownish-horn, lower mandible grey; legs dark brown to greyish-flesh. Sexes similar. Juvenile is rather uniform dark brown, with pale shaft streaks on crown to upper back, small dull wing spots, paler chin and throat centre, slightly paler and warmer underparts. Race *striata* is buffier above than nominate, with buff wing spots, slightly duller flanks and vent; *stevensi* is largest, colder dark olive-tinged buff above, colder and darker brown below, with only slight dull rufous edges on central breast and belly, chin and throat almost occluded by longer, broader grey-brown streaks; *proxima* is like previous but smaller, slightly brighter above, paler dull ochrous-buff below; *griseigularis* resembles last, but throat streaks greyer, more diffuse and extending onto whiter breast, with lower belly and vent rusty; *rufiventer* is slightly bigger than nominate, with broader dark edging above, buff wing spots, richer rufous below; *leucosticta* has entire underside broadly streaked dark olive-grey and stony white. Voice. Song consists of very variable, loud, clear, melancholy ringing whistles, repeated after intervals, “chi-oo”, “pee-oo”, “pree”, “chiu-ree”, “chewee-chui” and “pee-wi”, sometimes single “pweeee”. Also as alternating short upslurred “tseurp” and downslurred and then upslurred “tseur” whistles; alternating “tuhhéér, tuhwhit!...”; slow duet of a short, moderately downslurred “tseeur” and lower, moderately upslurred “tsurt”; strongly upturned “fuhwééti” or “fuhwééh”. When alarmed, utters prolonged harsh, buzzy, toneless, scolding “ttrreett” and “chrrreerrrr”, often interspersed with plaintive “wher” notes; other calls include excited, irregular chorus of short quick musical notes at various pitches, a sequence of alternating higher and lower hard staccato notes “chürk-urt-chürk-urt...”, and a hard, rising-and-falling, even-tempo churring trill.

**Habitat.** Broadleaf evergreen forest, often near rocky outcrops; limestone areas outside the range of *Gypsophila crispifrons*, and occasionally alongside latter, e.g. in E Tonkin (N Vietnam). Found at 300–2100 m in India, to 1830 m in SE Asia and China, but only above 610 m in Peninsular Malaysia.

**Food and Feeding.** Insects, grubs and small molluscs. Forages in pairs or small groups on ground, just above ground in dense or tangled vegetation, or around rocks and boulders.

**Breeding.** Jan–Jul. Nest described as an upright dome with entrance near top, a semi-dome or a deep cup made of dead leaves, dead bracken, grasses, rootlets, tendrils, semi-decayed bracken and fern fronds, and moss (materials often in rotten condition; nest can closely resemble a lump of rotting vegetation), lined with dry dead leaves or fine, pale hair-like material, often placed on ground, generally between boulders, but sometimes up to 0.6 m up in hollow in pile of boulders, recess in roadside or trailside bank, wedged in hollow near base of tree, or on mossy bank; often in damp situation, with outside of nest often sodden. Clutch 2–4 eggs (usually 3–4 in India and Myanmar, 2 in Peninsular Malaysia), white with numerous pinkish-red freckles, or with specks and blotches of reddish and pale pinkish-purple, or thinly and unevenly spotted with pale reddish-brown, purple-brown or brownish-mauve; incubation by both sexes; no information on duration of incubation and nestling periods.

**Movements.** Resident. Reports of some seasonal altitudinal movements require substantiation; other evidence suggests completely sedentary.

**Status and Conservation.** Not globally threatened. Generally common across range. Locally fairly common in NE hills of India, where fairly common in Nandapha National Park (Arunachal Pradesh). Local and uncommon in China, where rare in Shiwandashan National Nature Reserve and uncommon in Diding Nature Reserve (Guangxi). Locally common in Myanmar and Thailand. Common in Cardamom Mountains, in Cambodia. In Laos, occasional to frequent in Dong Hua Sao National Biodiversity Conservation Area (NBCA), and common in Nam Kading NBCA, Khammouan Limestone NBCA and part of Nakai-Nam Theun NBCA. In Vietnam, common in Tam Dao National Park but scarce in Cuc Phuong National Park; present in Thuong Da Nhim and Chu Yang Sin Nature Reserves (Da Lat Plateau, in S Annam), and in eight protected areas in the Annamese Lowlands Endemic Bird Area.

## 149. Eyebrowed Wren-babbler

### *Napothera epilepidota*

**French:** Petite Turdinule **German:** Streifenbrusttimalie **Spanish:** Ratina Cejuda  
**Other common names:** Small/Lesser/Streak-breasted Wren-babbler; Austen's Small Wren-babbler (*roberti*); Grant's Wren-babbler (*guttaticollis*)

**Taxonomy.** *Myiothera epilepidota* Temminck, 1828, Java.

Geographical variation considerable. Race *laotiana* often synonymized with *amyae*; birds of latter race from Tonkin (N Vietnam), however, much larger and longer-billed than other races, and further taxonomic investigation therefore required. Birds from SE Laos presumed to be assignable to *laotiana*. Race *bakeri* rather poorly differentiated from *davisoni* and perhaps better merged with it. Proposed race *mendeni* (from S Sumatra highlands) considered a synonym of *diluta*. Thirteen subspecies recognized.

**Subspecies and Distribution.**

*N. e. guttaticollis* (Ogilvie-Grant, 1895) – SE Bhutan and NE India (Arunachal Pradesh, E Assam).

*N. e. roberti* (Godwin-Austen & Walden, 1875) – NE Indian hill states S of R Brahmaputra, and NW Myanmar.

*N. e. bakeri* (Harington, 1913) – E & SE Myanmar.

*N. e. davisoni* (Ogilvie-Grant, 1910) – N & W Thailand and S Myanmar (N Tenasserim).

*N. e. amya* (Kinnear, 1925) – S China (SE Yunnan) and Vietnam (S to C Annam).

*N. e. laotiana* (Delacour, 1926) – N, C & SE Laos.

*N. e. delacouri* Yen Kwokying, 1934 – Yao Shan (EC Guangxi), in S China.

*N. e. hainana* (E. J. O. Hartert, 1910) – Hainan I.

*N. e. clara* (Robinson & Kloss, 1919) – S Annam (Vietnam).

*N. e. granti* (Richmond, 1900) – extreme S Myanmar (extreme S Tenasserim), S Thailand and Peninsular Malaysia.

*N. e. diluta* (Robinson & Kloss, 1916) – Sumatra.

*N. e. exsul* (Sharpe, 1888) – N & C Borneo.

*N. e. epilepidota* (Temminck, 1828) – W & C Java.

**Descriptive notes.** 10–11 cm. Small, streaky, virtually tailless babbler with rather long bill and prominent pale supercilium. Nominative race has crown and upperparts rich chocolate-brown with buff shaft streaks, latter strongest on mantle and back (where black edges also apparent), upperwing and tail brownish-black, upperwing-coverts, tertials and secondaries with vague buffy tips (wing spots); lores blackish, continuing through eye in dark eyestripe, postocular supercilium whitish, ear-coverts dark brown with whitish streaks, submoustachial area dark brown with whitish flecks; chin and throat whitish, breast, belly and upper

flanks dirty ochrous-brown with long whitish streaks, shading on lower flanks, thighs and vent to darker ochrous-brown; iris brown to hazel and red; upper mandible dark horn, lower mandible paler; legs brownish-flesh to horn-brown. Sexes similar. Juvenile is plain brown below, less clearly marked above, wing spots buff. Race *guttaticollis* is paler brown with little pale streaking above, paler grey-brown below, with more whitish streaking on lower underparts, whitish chin and throat with neat, irregular dark brown cone-shaped flecks; *roberti* is like previous, but toned buffy rufous above, below and on head side; *bakeri* is like last below but without the throat markings, and with buffy shaft streaks above; *davisoni* is very like preceding race, but with slight rufescent tinge above; *laotiana* also is similar, but less rufescent below, streaking slightly weaker; *delacouri* resembles previous, but supercilium tinged rufous, crown slightly rufescent; *amyae* is large and long-billed, more slaty brown overall, including ear-coverts, rump feathering copious; *hainana* is smaller than others, with heavier scaling on crown; *clara* is like *davisoni* but slightly colder above, with whiter throat, supercilium and underpart streaking; *granti* has paler centre of breast and belly; *diluta* is like nominate, but with ear-coverts and submoustachial area dark grey and a row of spots running down moustachial line and up behind ear-coverts; *exsul* has buffier throat than nominate, less clearly defined streaks on paler, buffier underparts. Voice. Song a thin clear sad falling whistle, “cheeoo”, “cheeooo” or “pitiii”, repeated at intervals of 2–5 seconds; may be accompanied by 1–2 call notes. When excited, may alternate song phrases with curious, slightly nasal, excited squeaky “chikachik-chikachik-chikachik...”, or “skreeti-skreeti...”. When alarmed, gives fairly subdued but prolonged rattles, e.g. “prrrt-prrrt-prrrt”, “wprrrt wprrrt wprrrt” and “chrrt-chrrt-chrrt”; other calls include loud rising “chyrk!”, often much repeated, and low repeated “pit pit pit”.

**Habitat.** Broadleaf evergreen forest, secondary forest, in Borneo in hilly mixed dipterocarp, damp gallery forest, and *Agathis* conifer forest and bamboo. (Reportedly favours areas with openings for streams or natural small glades, particularly in places strewn with mossy boulders, fallen epiphyte-laden trees, old stumps etc., but this requires substantiation.) Found at 300–1800 m in Indian Subcontinent, and 50–2135 m in SE Asia and China; c. 450–2000 m in Greater Sundas (700–1675 m in Borneo, 900–1800 m in Java).

**Food and Feeding.** Insects, including ants (Formicidae), grasshoppers, locustids and crickets (Orthoptera), and beetles (Coleoptera); also spiders (Araneae). Keeps in pairs or family parties, on forest floor and understorey. Hops among fallen leaves, turning them over to locate food, and creeps about in low undergrowth and tangles.

**Breeding.** Jan–Jun in SE Asia and Indian Subcontinent; Nov–Dec in Java. Nest a dome, semi-dome or cup, made of semi-decayed material (like that of *N. brevicaudata*), usually wedged among boulders, in leaf litter piled against boulder or steep bank, or in grass clump, generally on ground or, less often, slightly (less than 0.3 m) above it. Clutch 2–5 eggs (usually 4 in India and Myanmar, 2 in Peninsular Malaysia and Java), white to greenish-white, sparsely sprinkled with very small rusty to dull brown speckles (Peninsular Malaysia), or pale pinkish, peppered with pink and purple markings (Java); no information on duration of incubation and nestling periods; nestlings fed by both sexes.

**Movements.** Resident. Reportedly subject to seasonal altitudinal movements, wintering down to plains in Himalayas, but this requires substantiation (and contradicted by other evidence).

**Status and Conservation.** Not globally threatened. Generally fairly common to common across range. Rare in Bhutan (apparently one record, in 1936). Rare in India, with very few records. Fairly common but generally overlooked in China, where present in Bawangling National Nature Re-

serve, on Hainan. Present in Kaeng Krachan National Park, in Thailand. In Laos, occasional in Xe Pian National Biodiversity Conservation Area (NBCA), and present in Nam Kading, Nakai-Nam Theun and Hin Namno NBCAs. Fairly common in Cuc Phuong and Tam Dao National Parks, and present in Na Hang Nature Reserve, all in N Vietnam, and occurs in Thuong Da Nhim and Chu Yang Sin Nature Reserves (Da Lat Plateau, in S Annam); also in eight protected areas in the Annamese Lowlands Endemic Bird Area. In Borneo, scarce in Sabah, and present in Gunung Niut Nature Reserve (W Kalimantan). Present in Gunung Leuser National Park, in Sumatra. Common in Gunung Gede-Pangrango National Park, in W Java.

**Bibliography.** Ali & Ripley (1971), Andrew (1985), Buij *et al.* (2006), Chasen & Hoogerwerf (1941), Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paolai (1960), David-Beaulieu (1944, 1950), Davidson (1998), Davidson *et al.* (1997), Deignan (1963), Delacour & Jabouille (1931a), Dickinson & Chaiyaphun (1973), Duckworth *et al.* (1998), Eames (1995), Eames *et al.* (2001), Evans & Timmins (1998), Gore (1968), Grimmett *et al.* (1998), Hill (2000), Holmes (1996), Hume (1888), Hume & Davison (1878), King (1983), King & Liao Weiping (1989), Kinnear (1929), Lee Kwok Shing *et al.* (2006), Lekagul & Round (1991), Lewthwaite (1996), Ludlow & Kinnear (1944), MacKinnon (1988), Madoc (1956), van Marle & Voous (1988), Mayr (1938), Medway & Welik (1976), Meyer de Schauensee (1984), Nguyễn Duc Tu *et al.* (2001), Priemé & Heegaard (1988), Pui Lok *et al.* (2005), Rasmussen & Anderton (2005), Robinson (1928), Robinson & Kloss (1919a), Robson (2000), Robson, Eames, Nguyễn Cu & Truong Van La (1993a, 1993b), Robson, Eames, Wolstencroft *et al.* (1989), Round (1999), Sharpe (1889), Sheldon *et al.* (2001), Showler, Davidson, Chanthaxi Vongkhamheng & Khounmee Salivong (1998), Showler, Davidson, Khounmee Salivong & Khamkhoun Khounholine (1998), Singh (1995), Smith *et al.* (1943), Smythies (1986), Smythies & Davison (1999), Sody (1956), Spierenburg (2005), Stevens (1914), Stuart Baker (1893), Thewlis *et al.* (1996), Timmins & Trinh Viet Cuong (1999), Tizard *et al.* (1997), Wilkinson, Dutson & Sheldon (1991), Wilkinson, Dutson, Sheldon, Darjono & Noor (1991), Williamson (1945), Yen Kwokying (1934a).

## Genus *RIMATOR* Blyth, 1847

### 150. Long-billed Wren-babbler

#### *Rimator malacoptilus*

**French:** Turdinule à long bec **German:** Assamzwerigsäbler **Spanish:** Ratina Picuda

**Taxonomy.** *R[imator]. malacoptilus* Blyth, 1847, Darjeeling, India.

Formerly treated as conspecific with *R. pasquieri* and *R. albostratus*. Monotypic.

**Distribution.** Sikkim E to NE India (to Arunachal Pradesh; also, disjunctly to S, from Meghalaya E to Nagaland and N Manipur), N Myanmar and adjacent S China (NW Yunnan).

**Descriptive notes.** 11–12 cm; 18–21 g. Small, almost tailless streaky brown babbler with very long, slightly downcurving bill, blackish moustache. Crown, nape and head side are brown with tiny buff shaft streaks and very narrow black scaling, dorsal feathering long, brown, with long buff shaft streaks, fluffy rump plain and slightly chestnut, upperwing and tail plain brown with rufescent tinge; face (lores, superciliary area, cheek, ear-coverts, submoustachial area) more rufescent, slightly paler brown than crown and with fine buff streaks, moustachial streak and malar stripe dark brown (commonly forming long double line, but variable); chin and throat buff, shading to brown and buff streaking on elongate feathers of breast and flanks, buffier down middle underparts, browner at sides, with rusty-rufous thighs and vent; iris pale red-brown to brown; bill dark horn-brown, paler at tip; legs pale livid-fleshy, tinged brown or pale purplish-horn. Sexes similar. Juvenile apparently undescribed. **Voice.** Song a short (0.4 second) clear whistle, “chiiuh” or “fyeeé”, smoothly falling in pitch but gaining in volume, given every 2–10 seconds; also a similar “féeyew” which begins explosively and only slightly downslurred, quickly becoming much softer and steeply downslurred. When excited, may intersperse song with 1–3 quickly repeated “chip’wu” or “chitt’wu” phrases.

**Habitat.** Broadleaf evergreen forest, forest edge, bamboo, secondary growth, at 900–2000 m, probably rarely to 2700 m.

**Food and Feeding.** Invertebrates. Forages on floor and in undergrowth. Skulking; hops on ground and among low vegetation, rummaging among fallen leaves and mulch, evidently probing into ground (some specimens have had the bill caked with mud). Keeps in pairs.

**Breeding.** May–Jul in India. Nest a rather loose untidy globe with entrance near top, made of leaves, grasses, roots, bracken fronds and weed stems, lined with dead leaves, placed on ground, among a mass of dead leaves at foot of large tree or similar site. Clutch 4 eggs, white with faint lilac or sienna-pink tinge, with small dots and blotches of reddish-brown or purple-brown, and smears of reddish-brown or lilac-grey. No other information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Generally rare or, at least, rarely recorded. Rare in Bhutan; scarce in India, where present in Buxa Tiger Reserve (West Bengal) and Mehao Wildlife Sanctuary and uncommon in Eaglenest Wildlife Sanctuary (both in Arunachal Pradesh). Report from SE Xizang (S China) erroneous.

**Bibliography.** Ali & Ripley (1971), Allen *et al.* (1997), Choudhury (2000), Collar (2006), Grimmett *et al.* (1998), Han Lianxian (2000), Inskipp & Inskipp (1991), Koelz (1954), Rasmussen & Anderton (2005), Ripley *et al.* (1991), Robson (2000), Singh (1995), Smythies (1949, 1986), Spierenburg (2005), Stevens (1914, 1923), Stuart Baker (1901).

### 151. White-throated Wren-babbler

#### *Rimator pasquieri*

**French:** Turdinule de Pasquier **German:** Vietnamzwerigsäbler **Spanish:** Ratina Goliblanca

**Taxonomy.** *Rimator pasquieri* Delacour and Jabouille, 1930, Fan Si Pan [22°17' S 104°47' E], 2500 m, Tonkin, north Vietnam.

Formerly considered conspecific with *R. malacoptilus* and *R. albostratus*. Monotypic.

**Distribution.** Fan Si Pan Mts (W Tonkin), in N Vietnam.

**Descriptive notes.** 11–12 cm. Small, almost tailless streaky brown babbler with very long, slightly downcurving bill, prominent white throat. Crown, nape and head side are darkish rufescent brown with vague buff shaft streaks, dorsal feathering long, darkish brown and with long buff shaft streaks, becoming vague on fluffy dark rufescent rump, upperwing and tail plain darkish rufescent-brown; face (lores, superciliary area, cheek, ear-coverts) slightly paler, plainer brown than crown, submoustachial streak dark brown; chin, malar area and throat pure white, with clear-cut horizontal break to darkish ochre-tinged brown underparts; long whitish-buff shaft streaks on elongate feathers of breast and flanks, buffier down middle underparts, browner at sides, with dark brown thighs and vent; iris brown; upper mandible blackish, lower mandible greyish; legs brown. Differs from similar *R. malacoptilus* in having clean white chin and throat, including malar area and area under short submoustachial stripe, plain mouse-brown ear-coverts, whiter centres of long feathers of underparts, dark brown thighs and vent, and

parts: long whitish-buff shaft streaks on elongate feathers of breast and flanks, buffier down middle underparts, browner at sides, with dark brown thighs and vent; iris brown; upper mandible blackish, lower mandible greyish; legs brown. Differs from similar *R. malacoptilus* in having clean white chin and throat, including malar area and area under short submoustachial stripe, plain mouse-brown ear-coverts, whiter centres of long feathers of underparts, dark brown thighs and vent, and

slightly longer bill and legs. Sexes similar. Juvenile apparently undescribed. **Voice.** Song a whistled “chiiuh” or “tiiiuh”, very similar to that of *R. malacoptilus* but perhaps slightly longer, repeated at short intervals; when excited, intermingles song phrase with shorter “pi’wip”, “pit’wip” or “pit’rip” calls. Calls with low “prp” or “prt” notes.

**Habitat.** Broadleaf evergreen forest, secondary growth, and bamboo, at c. 1220–2000 m.

**Food and Feeding.** No information. Skulks on floor and in undergrowth; rummages among fallen leaves. Behaviour similar to that of *R. malacoptilus*.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Scarce within its tiny range, which includes Fan Si Pan National Park.

**Bibliography.** Collar (2006), Delacour & Jabouille (1930, 1931a), King *et al.* (1975), Robson (2000), Tordoff, L. & Manh Hung *et al.* (2002), Tordoff, L. & Trong Dat *et al.* (2001), Vò Quý (1971).

### 152. Sumatran Wren-babbler

#### *Rimator albostratus*

**French:** Turdinule à raies blanches **German:** Sumatrazwerigsäbler **Spanish:** Ratina de Sumatra

**Taxonomy.** *Rimator albostratus* Salvadori, 1879, Mount Singgalang, western Sumatra.

Formerly considered conspecific with *R. malacoptilus* and *R. pasquieri*. Monotypic.

**Distribution.** W Sumatra S to Mt Dempo.

**Descriptive notes.** 13 cm. Small, almost tailless streaky brown babbler with very long, slightly downcurving bill, white throat and prominent black malar. Crown, nape and head side are dark chestnut-tinged brown with vague buff shaft streaks, dorsal feathering long, dark chestnut-tinged brown, with long narrow whitish-buff shaft streaks disappearing on fluffy dark chestnut-tinged rump, upperwing and tail plain dark chestnut-brown; face (lores, superciliary area, cheek, ear-coverts) slightly paler brown than crown and with indistinct narrow whitish shaft streaks, dark brown moustachial streak and malar line (forming double line);

chin, submoustachial area and throat white or off-white, with slightly soft, oval-shaped edge on upper middle breast; breast side and rest of underparts ochre-tinged mid-brown with long whitish-buff shaft streaks on elongate feathers, streaks broader and whiter on mid-belly, brown thighs and vent; iris chestnut; bill dark greenish-slate to black; legs pale brown to brown. Differs from similar *R. pasquieri* in larger size and longer bill, darker crown with feathers smaller and less patterned, ear-coverts streaked pale, long black malar stripe below narrow whitish submoustachial streak, making white throat much narrower and with less clear-cut lower edge. Sexes similar. Juvenile apparently undescribed. **Voice.** Song a short, clear, bell-like “puu” or “puh”, slightly increasing in volume, and repeated every 4–6 seconds; when excited, mixed with quickly repeated but variable series of “whip’ip” or “whip-wip” calls. Calls with low “wrrt”, “trrrp” or “tr’h” notes.

**Habitat.** Lower montane oak–laurel forest, at 1200–2850 m.

**Food and Feeding.** Presumably invertebrates. Forages on forest floor. Two specimens were obtained when “running on a tall tree trunk”.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Present in Gunung Leuser and Kerinci-Seblat National Parks. Considerable effort was put into seeking more specimens than the two obtained during survey work in 1914, leading to the judgement that the species “must be very rare”.

**Bibliography.** Buij *et al.* (2006), Collar (2006), Holmes (1996), MacKinnon & Philipps (1993), van Marle & Voous (1988), Robinson & Kloss (1918, 1924b).

### 153. Indochinese Wren-babbler

#### *Rimator danjoui*

**French:** Turdinule de Danjou **German:** Kurzschwanzsäbler **Spanish:** Ratina Indochina  
**Other common names:** Danjou’s Babbler, Short-tailed Scimitar-babbler

**Taxonomy.** *Rimator danjoui* Robinson and Kloss, 1919, Lang Bian Peaks [c. 12°02' N 108°26' E], Annam, Vietnam.

Formerly placed in a monotypic genus, *Jabouilleia*, but apart from larger size exhibits no significant differences from present genus. In Vietnam, birds in NE Tonkin (with stronger black malar area and bold black-and-white feathering on belly) represent an as yet undescribed race, and those in Central Highlands of S part of C Annam (with brown of plumage colder and darker, rufous areas duller and paler, underparts and bill roughly intermediate between those of other races) another such. Three subspecies currently recognized.

**Subspecies and Distribution.**

*R. d. naungmungensis* (Rappole *et al.*, 2005) – Naung Mung area of Kachin State, in N Myanmar.  
*R. d. parvirostris* (Delacour, 1927) – Vietnam (SE Tonkin S to N part of C Annam) and adjacent C Laos.

*R. d. danjoui* Robinson & Kloss, 1919 – S Vietnam (S Annam).

**Descriptive notes.** 18–19 cm. Medium-sized short-tailed babbler, brown above, brown, buff and white below, with long, heavy, partly decurved bill. Nominata race has crown and upperparts olive-brown with very narrow pale shaft streaks, fluffy rump olive-brown, upperwing and tail brown with olive tinge; face (lores, supercilium, ear-coverts) grey-tinged olive-brown, long dark brown moustachial and malar lines with buffy submoustachial area, becoming buffy rufous on neck side; chin, throat and upper breast whitish with ochre-edged dark brown streaks (forming narrow necklace on breast), shading below to duller, darker ochreous-brown flanks, thighs and vent, mid-belly

On following pages: 154. White-hooded Babbler (*Gampsorhynchus rufulus*); 155. Collared Babbler (*Gampsorhynchus torquatus*); 156. Yellow-throated Fulvetta (*Pseudominla cinerea*); 157. Rufous-winged Fulvetta (*Pseudominla castaneiceps*); 158. Black-crowned Fulvetta (*Pseudominla klossi*); 159. Golden-fronted Fulvetta (*Pseudominla variegataiceps*); 160. Spiny Babbler (*Turdoides nipalensis*); 161. Iraq Babbler (*Turdoides altirostris*); 162. Common Babbler (*Turdoides caudata*); 163. White-throated Babbler (*Turdoides gularis*); 164. Striated Babbler (*Turdoides earlei*); 165. Slender-billed Babbler (*Turdoides longirostris*); 166. Large Grey Babbler (*Turdoides malcolmi*); 167. Arabian Babbler (*Turdoides squameiceps*).

**Food and Feeding.** Presumably insectivores. Occurs singly, in pairs or in small family parties. Forages on or just above ground, often among dense vegetation. Individuals observed in Laos appeared to be probing soil with the bill.

**Breeding.** Jan-Apr in Vietnam; clutch 2 eggs, perhaps more; family party of four in Vietnam in late May. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Annamese Lowlands EBA and Da Lat Plateau EBA. Formerly considered Vulnerable. Generally uncommon, locally fairly common; status in Myanmar unclear. Threatened by forest destruction throughout its range, particularly where it prefers forest at lower altitudes. Present in Nakai-Nam Theun National Biodiversity Conservation Area and the Nakai-Nam Theun Extension, in Laos. In Vietnam, fairly common in Bach Ma National Park and Ho Ke Go Nature Reserve, and present in Thuong Da Nhim and Chu Yang Sin Nature Reserves, and in eight protected areas in the Annamese lowlands; uncommon on Da Lat Plateau.

**Bibliography.** Anon. (2006d), Butchart & Stattersfield (2004), Collar *et al.* (2001), Delacour (1927), Delacour & Jabouille (1931a), Eames (1995, 2001), Eames, Eve & Tordoff (2001), Eames, Robson *et al.* (1992), Evans & Timmins (1998), Hui *et al.* (2001), Lê Mạnh Hùng *et al.* (2002), Nguyễn Cu *et al.* (2000), Rappole *et al.* (2005), Robinson & Kloss (1919a), Robson (2000), Robson, Eames, Nguyễn Cu & Truong Van La (1993a, 1993b), Robson, Eames, Wolstencroft *et al.* (1989), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Thewlis *et al.* (1998), Timmins & Trinh Viet Cuong (1999).

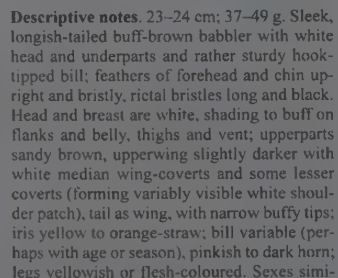

### 154. White-hooded Babbler

**French:** Gampsorin à tête blanche    **German:** Weißkopftimalie    **Spanish:** Timalí Cabeciblanco  
**Other common names:** White-headed Babbler/Shrike-babbler, Indian White-hooded Babbler

**Taxonomy.** *Glampsorhynchus*]. *rufulus* Blyth, 1844, Arakan, Lower Myanmar.

Formerly treated as conspecific with *G. torquatus*. Monotypic.

**Distribution.** SE Nepal E through S Bhutan to all NE Indian hill states, SE Bangladesh, N, W & C Myanmar and S China (W Yunnan).

lar. Juvenile has rufous head and breast side, shading into buff of underparts (usually more extensive, e.g. across breast). Voice. Song presumably an infrequently heard, short, soft mellow series of low whistles, a slightly rising "fui!" and more level "fwur". Typical call a loud hollow, rapid, nervous cackling "uh-uh-jō r'r'r'r'r", the "jō" greatly stressed and highest; first 1-2 notes sometimes given irregularly but frequently, often in manic manner, and sometimes a hollow, slightly accelerating laughter, "khúrk khúrk khúrk-khurk-khurk-khurk". Also brief, edgy, subdued, conversational twangy "éwrt!" notes.

**Habitat.** Bamboo and middle storey of broadleaf evergreen forest, secondary growth, scrub, bushes and long grass at edge of forest; up to 1200 m in India and 1400 m in Nepal, and at 200–900 m in Bhutan.

**Food and Feeding.** Presumably invertebrates. Forages c. 2–7.5 m above ground, mainly in bamboo canopy. Usually not shy, gregarious and noisy, invariably in parties of up to 20 individuals, often in association with other species, including other babbblers, particularly *Pomatorhinus ochraceiceps* and Greater Rufous-headed Parrotbill (*Paradoxornis ruficeps*).

**Breeding.** Apr–Aug. Nest a shallow, flimsy saucer, made of dead leaves, a few small twigs, roots, lichen and a little moss, untidily bound together with cobwebs, roots and tendrils, lined with fine grass, rootlets and tendrils, placed c. 2 m above ground in bush. Clutch 3–4 eggs, variable, pale yellowish, well covered with freckles and blotches of reddish-brown. No other information.

**Movements.** Resident. Apparently some type of displacement may occur, because described as a local migrant in Kawranj National Park, in India.

**Status and Conservation.** Not assessed. Scarce in E Nepal (two records). Uncommon in Bhutan, formerly known from two localities in C & E valleys. Fairly common in India, and present (at least formerly) in what is now Buxa Tiger Reserve (West Bengal), in NE India, present in (at least) Rajahmundry Wildlife Sanctuary, Nandamudi National Park (common) and Mouling National Park, all

in Arunachal Pradesh, occurs in Barail Reserve Forest and uncommon in Kaziranga National Park, both in Assam, and present in Ngengpui Wildlife Sanctuary and Dampa Tiger Reserve, in Mizoram. Rare in Bangladesh in Chittagong Hill Tracts. Locally fairly common in Myanmar. Uncommon in China.

**Bibliography.** Ali & Ripley (1948, 1971), Allen *et al.* (1997), Barua & Sharma (1999), Birand & Pawar (2004), Cheng Tsohsin (1987), Choudhury (2003), Collar (2006), Garthwaite & Ticehurst (1937), Godwin-Austen (1870), Grinnett *et al.* (1998), Hopwood (2012), Inskip & Inskip (1991), Katti *et al.* (1992), Koelz (1954), Mayr (1938), Oates (1883), Rasmussen & Anderton (2005), Ripley (1952), Robson (2000), Singh (1995), Smythies (1986), Spiereburg (2005), Stanford & Mayr (1941), Stanford & Ticehurst (1930, 1938), Stuart Baker (1893), Thompson & Johnson (2003).

*Gampsorhynchus torquatus*

**French:** Gambsorin à collier

**German:** Brustbandtimalie

**Spanish:** Timalí Acollarado

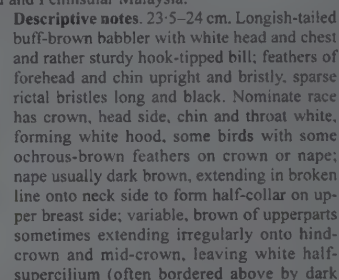

**Taxonomy.** *Gampsorhynchus torquatus* Hume, 1874, no locality = "the banks of the Younzaleen below the Pine forests in the Salween district". Tenasserim, Myanmar.

Formerly treated as conspecific with *G. rufulus*. Three subspecies recognized.

### Subspecies and Distribution.

*G. t. torquatus* Hume, 1874 – SE & S Myanmar (including N Tenasserim), W & N Thailand, S China (S Yunnan), NW & S Laos and C & S Vietnam (C & S Annam, Cochinchina).

*G. t. luciae* Delacour, 1926 – SE Yunnan (China), NE & C Laos and N Vietnam (Tonkin, N Annam).  
*G. t. saturator* Sharpe, 1888 – extreme S Thailand and Peninsular Malaysia.

brown continuation of half-collar); upperparts bright ochrous-brown, upperwing pale grey-brown with ochrous-brown fringes, tail pale grey-brown with whitish tips; breast tinged strongly buffy orange, underparts below this ochrous-buff, with whitish mid-belly (sometimes largely whitish with ochrous-buff flanks), thighs with some whitish and ochrous-brown flecks; iris pale or dull golden; bill greyish-white; legs greyish-brown. Differs from very similar *G. rufulus* mainly in having white of hood stopping at nape, which has partially concealed dark brown collar emerging more obviously on neck side and variably onto breast side, and in being richer, less sandy, above and below, with white shoulder patch much reduced. Sexes similar. Juvenile is thought to be identical to adult, thus different from rufous-headed juvenile of *G. rufulus*. Race *luciae* is rather variable, with rufescent-brown to blackish on crown, and white (with some admixed brown feathers) variably limited to forehead or extending over most of crown, dark collar bolder and more extensive than in other races; *saturator* is like nominate, but slightly darker above, and with more extensive buffy orange on underparts below half-collar. Voice. Song apparently unrecorded. Calls include harsh hard stuttering rattle or cackle, "rrrttttu-rrrttttu-rrrttttu...", "rrrut-rrrut..." or "rrrt-rrrt-rrrtt..."; and similar; also soft, very quiet "wit", "wet" and "weec" notes when foraging.

**Habitat.** Broadleaf evergreen forest, secondary growth, scrub and long grass at forest edge; associates particularly with bamboo. At 500–1800 m, locally down to 50 m in Vietnam.

**Food and Feeding.** Few data. Diet presumably invertebrates. Forages in lower and middle storey, mainly in bamboo. Gregarious and noisy, in parties. Evidence suggests behaviour exactly as that of *G. rufulus*.

**Breeding.** Testes enlarged in early Mar. No other information.

**Movements:** Resident.

**Status and Conservatn.** Not assessed. Generally fairly common, though uncommon in China. Common in Thailand, including in Kaeng Krachan National Park. In Laos, present but evidently local and uncommon in Dong Hua Sao National Biodiversity Conservation Area (NBCA) and present in Phou KhaoKhoay and Nakai-Nam Theun NBCAs, but common in Nam Kading NBCA. Common in Tam Dao National Park and present in Na Hang Nature Reserve, in N Vietnam, and occurs in four protected areas in the Annamese lowlands; scarce in Nam Bai Cat Tien National Park, in Cochinchina.

**Bibliography.** Cheng Tsoh-ho (1987), Cheng Tsoh-shin & Cheng Paolai (1960, 1962), Collar (2006), David-Beaulieu (1944), Davidson (1998), Deignan (1963), Delacour & Jabouille (1931a), Dickinson (1970), Duckworth *et al.* (1998), Eames *et al.* (2001), Engelbach (1932), Hill (2000), Hume & Davison (1878), Kinnear (1929), I.ekagul & Round (1991), Medway & Wells (1976), Meyer de Schauensee (1984), Nguyễn Đức Tu *et al.* (2001), Robinson (1928), Robinson & Kloss (1991a), Robson (2000), Robson, Eames, Nguyễn Cu & Truong Van La (1993a), Robson, Eames, Wolstenecroft *et al.* (1989), Showler, Davidson, Khounmee Salivong & Kharnkhoun Khounholine (1998), Smith *et al.* (1943), Thewlis *et al.* (1996).

### 156. Yellow-throated Fulvetta

**French:** Pseudominla à gorge jaune    **German:** Gelbkehlalappe    **Spanish:** Fulveta Goligualda  
**Other common names:** Yellow-throated Tit-babbler, Dusky Green Fulveta Tit-babbler

**Taxonomy:** *Minla cinerea* Blyth, 1847, Darjeeling, India.

**Distribution.** Sikkim F to NE Indian hill states (except Meghalaya), S China (SE Xizang, NW Yunnan) and adjacent N Myanmar; also SE part of N Laos and adjacent Vietnam (N Annam).

**Descriptive notes.** 10–11.5 cm. Tiny greyish babbler with yellow-fronted chestnut crown, white face with bold vertical subocular bar, and black and yellow wingpanels. Forehead is bright yellow, mid-crown to nape dull chestnut with narrow whitish shaft streaks, shading rustier on nape; upperparts olive-grey, upperwing and tail darker, plainer grey, but greater and primary wing-coverts black, carpal area white, fringes of flight-feathers yellow but black fringes of inner primaries (forming large wing flash with inner black panel); eyering (except for black frontal border), broad postocular supercilium, ear-coverts and nape sides

**Bibliography.** Anon. (2006d), Butchart & Stattersfield (2004), Cheng Tsohsin (1987), Collar *et al.* (2001), Dowell *et al.* (1997), King (1989a), Lee Kwok Shing *et al.* (2006), Meyer de Schauensee (1984), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Yen Kwokying (1934a, 1936), Zheng Zuoxin *et al.* (1987).

**Movements.** Resident.

**Bibliography.** Ali & Ripley (1971), Fleming (1953, 1959), Grinnett *et al.* (1998), Inskip & Inskip (1991), Proud (1959), Rand & Fleming (1957), Rasmussen & Anderton (2005), Ripley (1950b, 1953), Shrestha (1998), Stattersfield *et al.* (1998).

**Bibliography.** Al-Dabbagh & Bunni (1975, 1981), Cramp & Perrins (1993), Diessehorst (1962), Donaghy (2006), Harrison (1982), Hartert (1909), Kainady (1982), Murdoch (2005a), Richardson (2006), Scott *et al.* (1975), Snow & Perrins (1998), Stattersfield *et al.* (1998), Vaurie (1953b).

**Descriptive notes.** 20–26 cm; 30–40 g. Fairly small to medium-sized *Turdoides* babbler with rather slim decurved bill, fairly strong streaking above, mostly plain white and buff below but with some streaking on breast side or on breast. Nominative race has crown and upperparts dark buff (sometimes tinged cinnamon) with brown-edged dark brown streaks, becoming more diffuse on rump; buff-grey edges on mid-brown upwinging, and greyish-buff tail with dense but indistinct brown barring around shaft of central feathers. Iores and cheeks pinkish-tan, ear-coverts pinkish-tan to

**Habitat.** Scrub and bushes in semi-desert, borders of cultivation, thorn hedges, thickets, even in compounds; lowlands to 600 m.

**Distribution.** 25–27 cm. Very long-tailed, fairly large *Turdoides* babbler, dark-streaked above, with white breast and buffy-rufous belly. Forecrown and short narrow supercilium are greyish-white with narrow black streaks, shading to pinkish mid-brown with longer narrow black streaks on rest of crown and nape; and to pale olive-brown on back, upperwing and tail, tail with faint

A map of South Asia, including India, Pakistan, and Bangladesh, with a shaded region indicating the distribution of the genus *Pteropus*. The shaded area covers the northern and northeastern parts of the Indian subcontinent, including the Himalayan region and the northeastern states of India and Bangladesh.

**Bibliography.** Ali & Ripley (1971), Allen *et al.* (1997), Barua & Sharma (1999, 2005), Christison *et al.* (1946), David & Gosselin (2002b), Gaston (1978d), Godwin-Austen (1870), Grimmett *et al.* (1998), Harington (1909), Hume & Oates (1889), Inskipp & Inskipp (1991), Javed & Rahmani (1998), Khan (2005), Koelz (1954), Kylänpää *et al.* (2010), Macdonald (1907), Rasmussen & Anderson (2005), Robson (2010), Singh, A.P. (2000), Singh, P. (1998), Smythes (1986), Stanford & Ticehurst (1930), Stuart Baker (1893).

*Turdoides longirostris*

**Taxonomy.** *Pyelorchis longirostris* F. Moore, 1854, Nepal.

Also (race unknown) SW Myanmar.

*Turdoides malcolmi*

*Turdoides squamiceps*

A map of the Middle East and surrounding regions, including the Arabian Peninsula, the Indian subcontinent, and parts of North Africa and Europe. The study area, located in the northwestern part of the Arabian Peninsula, is highlighted in green. The map shows major geographical features and the location of the study area relative to the surrounding regions.

**Breeding.** Feb–Jul in Israel, May in United Arab Emirates and Mar–Apr in Oman; up to four broods may be produced by one female per season; dry conditions depress breeding activity in desert areas, but not near human settlements. Co-operative breeder, living throughout year in social groups of 2–23 (usually 6–13) individuals in territories of 0.2–1 km<sup>2</sup>; groups may be simple (with single breeding male), or multi-male (several males compete for or mate with new dominant female, subsequently reverting to simple structure as one male achieves dominance), or complex (several females and several males breeding together following break-up of previous structure owing to death and/or invasion). Nest, built mainly by dominant male and female, often assisted by other group-members, a large, untidy, rather deep cup, sometimes slightly domed, made of grasses, rootlets, twigs, bark and similar dead material, unlined or lined with some hair and a few feathers, placed up to 7 m above ground in tree fork, crown of bush or similar sheltered site; only one active nest in group territory at any one time. (Clutch laid by dominant female 3–5 eggs (other females often lay in same nest, so that nest can contain 6–13 eggs), plain turquoise; incubation by male.

females in group, period 14–15 days; chicks brooded and fed by all of group, nestling period 14 days, sometimes 17–19 days; fledglings fed by all group-members for up to c. 8 weeks; c. 30% of males remain in and inherit natal breeding group and territory, while c. 50% move to adjacent territory (most dominant son in group typically invades neighbouring territory, taking with him younger male siblings except second-ranking son, which stays in natal group); most females disperse to other groups at 2–4 years (typically in small party led by dominant daughter with younger female siblings or widowed mother), 50% settling in neighbouring territory while others may cross 3–4 territories. Single-female clutches generally more successful than multiple-female clutches, owing to egg breakages by disputing females and to smothering of late-hatching chicks by older nestlings; much nest failure due to intra-group and inter-group conflict, also to predation by snakes and, to lesser extent, Southern Grey Shrike (*Lanius meridionalis*). Age of first breeding 2 years, although many individuals not until much later, e.g. 6 years. Oldest ringed individual at least 15 years; annual mortality of first-years 32–62%.

**Movements.** Resident. In Israel, individuals may move only a few kilometres from their parental territories. In C' Arabia can be rare in Nov–Jan, suggesting that there is some degree of winter

dispersal; in S Oman disperses into desert after breeding, with groups reassembling in following spring.

**Status and Conservation.** Not globally threatened. Local breeder in F: Sinai, in Egypt. In Israel, locally fairly common from Dead Sea S into Negev Desert, numbers having expanded since 1950s in response to human colonization and agricultural settlement; rough estimate suggests a few hundred groups present in country, with total of 17 groups in 65 km<sup>2</sup> in S Arava in 1985, and 15–23 groups (totalling 65–220 individuals) in 25 km<sup>2</sup> around Hazeva in 1979–1983. Widespread but local, and relatively uncommon in Oman.

**Bibliography.** Abraham (2006), Anava *et al.* (2000, 2001a, 2001b, 2001c, 2001d, 2002), Bishop & Groves (1991), Brown (1975), Carlisle & Zahavi (1986), Castell (2000), Cramp & Perrins (1993), Edelaar & Wright (2006), Gallagher & Woodcock (1980), Goodman & Meininger (1989), Jamieson & Marshall (1999), Kalishov *et al.* (2005), Kam *et al.* (2003), Lundy *et al.* (1998), Maklakov (2002), Naguib *et al.* (1999), Ostreicher (1997, 1999, 2001, 2003, 2006), Pozis-François *et al.* (2004), Shirihai (1996), Wardman & Warrington (1997), Wright (1997, 1998a, 1998b, 1999), Wright & Dingemanse (1999), Wright, Berg *et al.* (2001a, 2002b), Wright, Maklakov & Khazin (2001c), Wright, Parker & Lundy (1999), Zahavi (1974, 1988, 1989, 1990, 1995).

## 168. Fulvous Babbler

### *Turdoides fulva*

French: Crat  pe fauve German: Akaziendrossling Spanish: Turdoide Rojizo  
Other common names: Fulvous Chatterer

**Taxonomy.** *Turdus fulvus* Desfontaines, 1789, Gafsa, Tunisia. Has been thought to form a superspecies with *T. rubiginosa*. Four subspecies recognized.

#### Subspecies and Distribution.

*T. f. maroccana* Lynes, 1925 – NE Morocco and NW Algeria.  
*T. f. fulva* (Desfontaines, 1789) – N Algeria, Tunisia and NW Libya.  
*T. f. buchanani* (E. J. O. Hartert, 1921) – WC Mauritania and N Senegal E to S Algeria and W Chad.  
*T. f. acaciae* (M. H. C. Lichtenstein, 1823) – N & E Chad, N & C Sudan, N Eritrea and N Ethiopia; also extreme S Egypt (at least formerly).

**Descriptive notes.** 25 cm; 46–70 g. Medium-sized sandy-brown featureless *Turdoides* babbler with whitish throat, blackish bill and longish graduated tail. Nominat race is rufescent-tinged sandy brown above, crown with fine dark streaks, upperparts with more diffuse dark streaks on mantle and back; lores to ear-coverts dusky greyish-brown, neck side greyish sandy-brown with diffuse dark streaks; chin whitish, throat, upper breast, flanks and vent bright sandy buff, with faint buff shaft streaks on upper breast; lower breast to belly creamy buff; iris brown to reddish-brown; bill greyish-black; legs olive-brown to yellowish-grey.

Sexes similar, but male has a touch of yellow at base of bill. Juvenile is paler, more yellowish-buff above, than adult, with grey iris and no crown streaks. Race *maroccana* is slightly darker above than nominate, with sandy-rufous wash on breast and flanks, iris pale grey; *buchanani* has paler crown, slenderer bill; *acaciae* has greyish-brown crown, yellowish bill with dark tip. **Voice.** Varied, but chorus song unreported. Main contact call a series of 6–10 loud, clear, descending whistles lasting altogether 2–3 seconds, the first note longest, "peeeoooo, peeeo-peeeo-peeeo-peeeo-peeeo". Other calls include shimmering metallic trill, "rtrrrrrrrrr", which rises and falls in pitch and intensity, possibly in mild alarm; a descending trill in distraction display; a high wavering tremolo by female on nest when fed by group-member; sharp "pwit" in high alarm; short twanging "pip" or "pee" in flight; quiet "cheep" while foraging.

**Habitat.** Desert scrub, bush-studded dry grassland, thorny desert thickets, tree clumps in barren arid land, and dry riverbeds, keeping to lower parts of shady thorn trees such as *Acacia*, *Ziziphus* and *Capparis*, and *Phoenix* palm clumps and *Tamarix* in wadis and oases; depressions with *Rhus tripartita*; will use *Eucalyptus* plantations, introduced tobacco stands and thorn-brake fencing.

**Food and Feeding.** Invertebrates, small seeds, grain and berries (notably of *Ziziphus* and *Salvadora*), varying seasonally. Animal items include small beetles (Coleoptera) and grasshoppers (Orthoptera) as commonest prey, also caterpillars, flies (Diptera), ants (Formicidae) and termites (Isoptera), one stomach holding 6 beetles and 50 termites, another (juvenile) 7 large caterpillars. Becomes tame and bold if provisioned in desert camps, taking scraps of dough, dead moths and pieces of meat. Forages mainly on ground, probing with bill at earth or in bases of palm fronds near ground; seen to extract larvae from basal fleshy leaves and underground rootstock of awn grass (*Aristida pungens*), using feet and bill. Found in small parties of 4–5 individuals, sometimes up to twelve; mean of 33 flocks 5.7 (Sudan), of 83 flocks 5 (Morocco).

**Breeding.** Apr and Aug in Mauritania, and Jan–Jun and recently fledged juveniles in Sept and Nov in Morocco; Nov–Jul (mostly Mar–Apr) in Algeria, Mar–Jul in Tunisia, Feb in Libya and May–Oct in Mali; adults feeding young in Jun–Jul in Niger; Aug (wet-season breeder) in Chad; Nov and Jan–May (including Mar–Apr at Gebel Elba) in Sudan and Nov and Mar in Ethiopia. Co-operative, probably monogamous breeder, with helpers (immatures); at six nests in Sudan, five pairs had one such helper and the other had two. Nest a loose deep cup of thin twigs, long coarse dry grass, rushes and bulrush (*Typha*) leaves, sparsely lined, placed 1–2 m up in dense thorn bush (*Ziziphus*, *Balanites*), brushwood or palm crown, once in dense prickly side growth of date palm. Clutch 3–6 eggs, usually 4–5 (mean of 24 clutches in Algeria 4.3), greenish or turquoise-blue. No information on incubation and nestling periods. Fan-tailed Raven (*Corvus rhipidurus*) known to prey on nests.

**Movements.** Resident; also short-distance nomad in response to rains.

**Status and Conservation.** Not globally threatened. Frequent and locally common in Morocco and adjacent Algeria, Tunisia and N Libya. Rare in Senegal, where possibly a recent colonist. Frequent in R Senegal valley, in Mauritania. Locally frequent in Niger. Frequent and widespread in Tibesti, in Chad. Common in middle latitudes E to Blue Nile, in Sudan. In Egypt, became extinct in Nile Valley following construction of Aswan High Dam in 1960s, but still common around Gebel Elba, on coastal Egyptian–Sudanese border.

**Bibliography.** Barlow *et al.* (1997), Borrow & Demey (2001), Bundy & Morgan (1969), Cave & Macdonald (1955), Cramp & Perrins (1993), David & Gosselin (2002b), Densley (1993),   tch  copar (1970), Fry *et al.* (2000), Goodman & Atta (1987), Goodman & Meininger (1989), Isenmann & Moali (2000), Ledant *et al.* (1981), Morel & Morel (1990), Nikolaus (1987), Th  venot *et al.* (2003), Thomsen & Jacobsen (1979), Urban & Brown (1971), Vaurie (1954b).

## 169. Bare-eyed Babbler

### *Turdoides aylmeri*

French: Crat  pe d'Aylmer German: Schuppenbrustdrossling Spanish: Turdoide de Aylmer  
Other common names: (Pale-billed) Scaly Babbler, Scaly Chatterer

**Taxonomy.** *Argya aylmeri* Shelley, 1885, Somalia.

Races *boranensis*, *keniana* and *mentalis* are all very similar, each exhibiting apparent colour variation; taxonomic reassessment perhaps warranted. Proposed race *loveridgei* (SE Kenya and extreme NE Tanzania) considered synonymous with *keniana*. Four subspecies recognized.

#### Subspecies and Distribution.

*T. a. aylmeri* (Shelley, 1885) – Somalia and SE Ethiopia.  
*T. a. boranensis* (Benson, 1947) – S Ethiopia and N Kenya.  
*T. a. keniana* (F. J. Jackson, 1910) – C & S Kenya and immediately adjacent NE Tanzania.  
*T. a. mentalis* (Reichenow, 1887) – NE & EC Tanzania.

**Descriptive notes.** 21–23 cm; 31–42 g. Small *Turdoides* babbler with long graduated tail, grey-brown above with rusty crown, buff below with small scaling and spotting on breast. Nominat race has crown and head side dull rusty brown with small buff flecks, upperparts, including upperwing and tail, paler ashy brown; lores pale buff, bare skin around and behind eye pale blue or bluish-grey, cheek, ear-coverts and neck side pale brown with buffy mottling; chin to breast pale brown to mid-brown with dense buff scaling or spotting, flanks greyish-buff, belly and vent warm buff; iris yellow to yellowish-white; bill pale yellowish-horn; legs pale horn-brown. Sexes similar. Juvenile is browner, less ashy, above than adult, scaling less distinct or absent, bill bronzy brown, paler at base, iris brown. Race *boranensis* is darker brown overall than nominate, with blackish-chestnut crown, rufescent sandy-buff underparts; *mentalis* is like previous, but slightly more ashy brown; *keniana* is richer brown generally, head more chestnut-brown, pale brown below. **Voice.** Chorus song unreported, but voice poorly known. Continuous mouse-like squeaking from foraging flock, described also as a "squeaking wood-screw" and "metallic, scraping and ratchet-like", varied by thin high chatter and broken whistling.

**Habitat.** Dense, arid thorn-scrub, woodland undergrowth, bushland, riverine thickets, tall thorn-brakes enclosing fields, dense euphorbias, grass and aloes, *Sansevieria* belts where planted to make corrals; favours *Commiphora*, at least in parts of Ethiopia, and in Somalia noted particularly where thornbush intermingles with clumps of *Euphorbia*. Found at 915–1370 m in Ethiopia; to 1350 m in Somalia and to 1500 m in Kenya.

**Food and Feeding.** Diet apparently unreported; presumably mainly invertebrates and small fruit and seeds. Found singly, in pairs or in small groups of 5–10 individuals.

**Breeding.** Mar–Apr and Aug–Sept in Ethiopia and Dec in N Tanzania. One nest described as a rather large, strong cup made of twigs and stems, lined with fine grasses, and placed 1.5 m up in bush among aloes and euphorbias. Full clutch size apparently not documented; eggs pale blue-green. A group of this species seen to mob a puff-adder (*Bitis*). No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Locally common to uncommon. Very common (locally one of the commonest bird species) but patchily distributed in NW Somalia; uncommon in Ethiopia; uncommon and very local in Kenya and Tanzania.

**Bibliography.** Archer & Godman (1961), Ash & Miskell (1983, 1998), Benson (1946), Britton (1980), David & Gosselin (2002b), Erlanger (1905), Friedmann (1937), Fry *et al.* (2000), Fuggles-Couchman & Elliott (1946), Jackson & Schlater (1938), Lewis & Pomeroy (1989), Stevenson & Fanshawe (2002), Urban & Brown (1971), Zimmerman *et al.* (1996).

## 170. Rusty Babbler

### *Turdoides rubiginosa*

French: Crat  pe rubigineux German: Heuglindrossling Spanish: Turdoide Herrumbroso  
Other common names: Rufous Chatterer

**Taxonomy.** *Crateropus rubiginosus* R  ppell, 1845, Shoa, Ethiopia.

Often placed in genus *Argya*. Has been thought to form a superspecies with *T. fulva*. Races *bowdleri* and *schnitzeri* previously referred to as, respectively, *sharpii* and *emini*, but last two names are preoccupied. Four subspecies recognized.

#### Subspecies and Distribution.

*T. r. rubiginosa* (R  ppell, 1845) – S Sudan, NE, C & S Ethiopia, S Eritrea, Djibouti, NE Uganda and Kenya (except SE).  
*T. r. bowdleri* Deignan, 1964 – SE Ethiopia and adjacent NE Kenya.  
*T. r. heuglini* (Sharpe, 1883) – S Somalia, SE Kenya, and NE & E Tanzania.  
*T. r. schnitzeri* Deignan, 1964 – N & NC Tanzania.

**Descriptive notes.** 19–23 cm; 33–61 g. Smallish *Turdoides* babbler, olive-brown above and yellowish-rufous below. Male nominate race has crown, upperparts, upperwing and tail brown with warm olive tinge, forehead marginally darker with narrow silvery-white streaks; lores, ear-coverts and neck side olivaceous grey-brown, cheek and subnuchal area pale brownish-buff; chin pale buff, becoming rufous-buff on throat and yellowish-rufous on remaining underparts, breast with almost imperceptible fine whitish shaft streaks; iris clear pale yellow to straw; slightly decurved bill olive-brown on upper mandible, paler and greenish on lower mandible, or all horn with flesh base of lower mandible; legs pale greyish-brown to flesh-olive. Female is like male, except for pale greenish-yellow iris. Juvenile is paler than adult, more russet above, with greyish-brown iris and fewer silvery-white streaks. Race *bowdleri* is larger than nominate; *heuglini* is darker above, richer brick-red below, with pale rufous lores, indistinct narrow blackish streaks on crown and mantle; *schnitzeri* is warmer and browner above, richer below, with more silvery-white streaks on crown (giving greyish appearance), shorter wing, somewhat thinner bill. **Voice.** Chorus song involves group participation in presumed male song, more usually given alone: a tinkling twitter series of 4–9 notes, often rising in pitch and sometimes

On following pages: 171. Rufous Babbler (*Turdoides subrufa*); 172. Jungle Babbler (*Turdoides striata*); 173. Orange-billed Babbler (*Turdoides rufescens*); 174. Yellow-billed Babbler (*Turdoides affinis*); 175. Black-lored Babbler (*Turdoides melanops*); 176. Sharpe's Babbler (*Turdoides sharpei*); 177. Dusky Babbler (*Turdoides tenebrosa*); 178. Reinwardt's Babbler (*Turdoides reinwardtii*); 179. Brown Babbler (*Turdoides plebejus*); 180. White-headed Babbler (*Turdoides leucocephala*); 181. Arrow-marked Babbler (*Turdoides jardineii*); 182. Scaly Babbler (*Turdoides squamulata*); 183. Northern White-rumped Babbler (*Turdoides leucopygia*); 184. Southern White-rumped Babbler (*Turdoides harilaui*); 185. Hinde's Pied Babbler (*Turdoides hindei*); 186. Northern Pied Babbler (*Turdoides hypoleuca*); 187. Southern Pied Babbler (*Turdoides bicolor*); 188. Bare-cheeked Babbler (*Turdoides gymnogyns*).

decreasing in pitch and volume. "pa-pee-pee-see-pit-hy-see-ah" or "tsce-see-see-ee-ee-ah" or "skeek-eeek-eeek-eeet-tee-peeet-peeet". Common call a shrill descending quavering "tschyeerss", repeated at intervals of 2–3 seconds; other calls include variety of growling, guttural and chattering notes, a curious soft "kwier" or "pseececo" (may be an alarm note), soft "pee", "dit", also "peew" notes (these last presumably among the high-pitched soft notes reported as often missed by observers).

**Habitat.** Mixed thorn and semi-leaved open forest, thickets in grassy *Commiphora* and *Acacia* woodland, thick matted growth inside juniper woods, thick bush along and between rivers or other dense cover, bushes in dry grassland, bushy luggas, degraded bushland, dry savanna, thick coastal scrub with baobabs, thickets, gardens, bushy pastures. Found at up to 1220 m in Tanzania, and over 2000 m in Kenya; generally in lowlands in Uganda, but to 2000 m on Mt Morongole; 1220–1675 m in Ethiopia.

**Food and Feeding.** Mainly invertebrates, including termites (Isoptera); also mango and papaya rinds. Forages on ground in leaf litter under bushes, bounding about, pulling at, picking and tossing debris about, tearing at wax and debris at honeyguide (Indicatoridae) feeders. Found in groups of 3–13 individuals, usually 4–5. Subordinate to *T. plebejus*, but groups follow those of latter, foraging behind them, bathing after them, approaching them to observe, occasionally feeding with them; forages also with francolins (*Francolinus*) at times, and with other birds.

**Breeding.** Aug. and feeding young in Jun, in Ethiopia and nest-building in Mar in Somalia; all year in E Africa, although Apr–Oct in Uganda; probably multi-brooded. Lives in territorial group, occupying relatively large area (so that groups rarely near one another); co-operative breeder. Nest an untidy open cup made of thin twigs, plant stems, leaves, leaf rims, and rush-like or other grasses (often with living stems woven in), lined, sometimes scantily, with roots and fine grasses or grass heads, placed 0.3–3 m up in creeper tangle, thick bush or leafy tree, once in dense mass of *Bougainvillea*. Clutch 2–4 eggs (usually 3 in Ethiopia), blue. No information on incubation and nestling periods. Brood parasitism by Jacobin Cuckoo (*Clamator jacobinus*) occurs. Nest destruction by primates recorded.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Frequent to common in Rift Valley and NE Ethiopian lowlands near Djibouti, and frequent in S. Common in SE Sudan and N Uganda. In Somalia, locally very common in the Jubba and lower Shabelle valleys and adjacent coastal plains. Known to be present at 98 localities in Tanzania by year 2000.

**Bibliography.** Ash & Miskell (1983, 1998), Benson (1946), Britton (1980), Carswell *et al.* (2005), Cave & Macdonald (1955), David & Gosselin (2002b), Duckworth *et al.* (1992), Erlanger (1905), Friedmann (1937), Fry *et al.* (2000), Harvey (1974), Huels (1982), Jackson & Selater (1938), Lewis & Pomeroy (1989), Nikolaus (1987), Safford *et al.* (1993), Schmidt (1982), Selater & Moreau (1932), Serle (1943), Short & Horne (2006), Stevenson & Fanshawe (2002), Urban & Brown (1971), Zimmerman *et al.* (1996).

## 171. Rufous Babbler

### *Turdoides subrufa*

**French:** Cratérope roussâtre **German:** Graustrindrossling **Spanish:** Turdoide Rufo  
**Other common names:** Rufous-backed Babbler

**Taxonomy.** [Himalia]. *subrufa* Jerdon, 1839, the Wynaad, near Manantoddy, Tamil Nadu, India. Two subspecies recognized.

**Subspecies and Distribution.**

*T. s. subrufa* (Jerdon, 1839) – W peninsular India S to S Karnataka and N Tamil Nadu.

*T. s. hyperythra* (Sharpe, 1883) – SW India (Kerala and W Tamil Nadu).

**Descriptive notes.** 24–25 cm; 57–78 g. Medium-sized *Turdoides* babbler, rich brown above and rufous below, with fairly stout black and yellow bill, dark lores and greyish forehead. Nominata race has forehead to mid-crown dull grey with dense fine black lines, shading to rich olive-tinged brown on rest of crown and upperparts, upwelling and tail, tail with barely visible close barring; lores darkish brown-grey, head side otherwise as hindcrown; entire underside dull rufous, buffier on mid-line of belly, greyer and darker on flanks and dusky on vent; iris creamy white to dark grey; upper mandible dark horny

brown, lower mandible bright yellow; legs dusky yellow. Sexes similar. Juvenile is deeper, richer brown above than adult. Race *hyperythra* is more richly coloured than nominate. Voice. Calls given in chorus are bursts of very rapid, shrill whistling trills, "tree-tree-tree", notes short, reedy, variably pitched and similar in quality to sound of a large cricket (Orthoptera), sometimes without a break for 10 seconds or more, preceded and punctuated occasionally by one or two harsh squeaks. Same squeaks constitute alarm call; also gives harder churring and clicking "tsu-wick!" or "tschick!", sometimes combined with or leading into trills.

**Habitat.** Dense scrub undergrowth in more open broadleaf evergreen and moist deciduous forest, forest edge, overgrown clearings, dense scrub and tall grass, bamboo brakes, mixed woodland and grass, abandoned coffee plantations; at 825–1220 m.

**Food and Feeding.** Insects, also berries (particularly of *Lantana*), and nectar of *Erythrina*, *Salmaal* and other flowers. Found in parties of 6–8 individuals. Forages on ground, but ventures up into trees. Very skulking, usually creeping about out of sight in low vegetation.

**Breeding.** Feb–Nov, mainly Feb–May. Nest a large rough strong deep cup made of leaves, grasses, ferns and fern stems, lined with fine grasses and roots, placed in bush or small tree. Clutch usually 4 eggs, clear blue with faint greenish tinge. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in Western Ghats EBA. Rare in N sector of range, but fairly common in Kerala and W Tamil Nadu. Present in Mudumalai National Park (Tamil Nadu), and in surveys 1973–1997 found in 23 areas, including eight protected areas, namely Sultan's Battery, Silent Valley, Parambikulam, Munnar, Periyar East, Periyar West, Termini and Akashan.

**Bibliography.** Ali (1942), Ali & Ripley (1971), David & Gosselin (2002b), Gokula & Vijayan (1997), Grimmett *et al.* (1998), Hume & Oates (1889), Rasmussen & Anderson (2005), Stattersfield *et al.* (1998), Whistler & Kinnear (1932), Zacharias & Gaston (1993, 1999).

## 172. Jungle Babbler

### *Turdoides striata*

**French:** Cratérope de brousse **German:** Dschungeldrossling **Spanish:** Turdoide Matorralero  
**Other common names:** Striated Babbler; Deccan Babbler (*somervillei*)

**Taxonomy.** *Cossyphus striatus* Dumont de Sainte Croix, 1823, Bengal, India.

May form a superspecies with *T. rufescens*, and has been treated as conspecific. Race *somervillei* sometimes thought to represent a separate species, but intergrades with *malabarica*. Proposed race *orissae* (from E India) treated as synonymous with nominate. Five subspecies recognized.

**Subspecies and Distribution.**

*T. s. sindiana* (Ticehurst, 1920) – Pakistan (R Indus plains) and NW India (from Himalayan foothills, Punjab and Haryana S to Rann of Kutch).

*T. s. striata* (Dumont de Sainte Croix, 1823) – Himalayan foothills from SE Himachal Pradesh E to S Nepal, S Bhutan and W Assam, and S in India to Uttar Pradesh, Bihar, S West Bengal and NE Andhra Pradesh, and Bangladesh.

*T. s. somervillei* (Sykes, 1832) – W peninsular India (S to Goa).

*T. s. malabarica* (Jerdon, 1845) – SW India.

*T. s. orientalis* (Jerdon, 1845) – peninsular India except W & NE.

**Descriptive notes.** 25 cm; 55–84 g. Medium-sized *Turdoides* babbler with pale eye, whitish lores, yellow bill and dull brownish-grey plumage, softly streaked on back and breast. Nominata race has crown and nape brownish-grey, upperparts drab grey-brown, mantle and back with a few long, soft-edged dark brown streaks, rump and uppertail-coverts greyish, tinged yellowish-rufous on uppertail-coverts; upperwing dark brown with ashy edges, tail dark greyish-brown, darker and noticeably barred towards tip; lores whitish with narrow dark line above, face and neck side plain brownish-grey; chin and throat pale dull grey with vague darker

bars, breast ashy yellowish with paler feather centres and shafts, belly, vent and undertail-coverts dull yellowish-rufous, tinged brown on flanks and with faint white shaft streaks; iris yellowish-white or creamy white, orbital skin pale yellow; bill yellow, yellowish-white, dirty whitish or, rarely, pale horny yellow; legs fleshy-yellow to yellowish-white. Sexes similar. Juvenile is paler than adult, upperparts and head pale brown, underparts rufescent, brownish on breast, primary fringes ochraceous. Race *sindiana* is more ashy above than nominate, and more creamy buff on belly; *somervillei* is highly distinctive, much browner and rustier overall, striations on mantle less marked, rump and uppertail-coverts yellowish-rufous, tail yellowish-chestnut, flight-feathers blacker, pale centres of breast feathers more pronounced; *malabarica* is more brownish-grey than nominate, particularly on tail; *orientalis* is like nominate but slightly browner above, with rufous tinge at tail end. Voice. A harsh conversational "ke-ke-ke" uttered when on the move, frequently breaking out into loud discordant chorus of squeaking and chattering. Calls include overexcited, peevish, slightly nasal, wheezy, variable chortling, e.g. "(trit, trit, tyurr, tyurr, tyurr, tyurr-tyur-tyit'itritritrit)", each note strongly descending; a gruff "kyarsh", often in series, or delivered rarely almost as rattle, very often accompanied by sharp squeals; subdued single asthmatic toneless "kürshh"; short descending metallic whinny; low, harsh, buzzy, twangy "churweeur, chnur, chnur-chnur..." and variants, long first note ascending and then descending sharply, others level and short; when mobbing predator, rapid sharp rattling interspersed with high-pitched squeals, also a harsher rattling.

**Habitat.** Open forest and secondary forest, patches of moist deciduous forest, scrubland, bamboo, gardens, cashew and jack-fruit gardens, orchards, hedges in cultivation, bushes on waste ground, mango groves, sheesham plantations with tall coarse grass, tamarisk jungle, hillsides with scrub and mixed forest; distribution in Assam may be linked with that of sal (*Shorea robusta*) forest. To 1525 m, locally 1830 m.

**Food and Feeding.** Wide range of invertebrates, mainly insects, including hymenopterans (ants, wasps, ichneumon flies), beetles (Coleoptera), grasshoppers and crickets (Orthoptera), cockroaches (Blattodea), caterpillars, moths (Lepidoptera), mantises (Mantodea), stick-insects (Phasmida), bugs (Hemiptera), also spiders (Araneae); also frogs; also grain, seeds, figs (*Ficus*), berries (including those of *Lantana* and *Ziziphus*), and nectar of *Salmaal*, *Butea*, *Erythrina* and *Helicteres isora*. In one study, plant matter accounted for 56% of diet by weight, involving pulp of fruit, pearl millet, wheat and leafy material; remaining food was lepidopterans (18%), hymenopterans (6%), orthopterans (6%), beetles (4%), snails and spiders (less than 1%), with remaining 10% unidentified. In another study, 22% of total food by volume was insects (mostly beetles), 74% bajra grain (*Pennisetum typhoides*), 4% other vegetable material. Very gregarious, in parties of 6–12 individuals throughout year; large flocks break up into smaller groups during breeding season. Often forms nucleus of mixed-species foraging parties. Occasionally associates with *T. affinis*. Spends much time on ground.

**Breeding.** In India all year, mainly Feb–Oct (with spring and mid-summer peaks) in NW & W and mainly Apr–Dec in SW. Social breeder, but does not nest colonially; different pairs in flock apparently breed consecutively, rather than concurrently; breeding birds continue to remain with a flock, detaching themselves only to attend to nest. Nest, built by both sexes and sometimes one or more helpers, a fairly loose, deep or shallow cup, made of grasses, roots, leaves, creeper tendrils and twigs, scantily lined with rootlets and fine grasses, placed 1.2–9 m (usually 2–4 m) above ground in bush, shrub, hedge, small tree or hollow tree stump. Clutch 3–7 eggs (usually 3–4), pale blue to deep dull blue, often tinged green (perhaps tending darker in S); more than one female may lay in one nest, female eating own new-laid egg recorded; incubation period 15 days; nestlings fed by both sexes, sometimes also by one or more helpers, no information on duration of nestling period. Brood parasitism by Jacobin Cuckoo (*Clamator jacobinus*) and Common Hawk-cuckoo (*Cuculus varius*) reportedly common. Of 77 eggs in 23 nests in one study, three failed to hatch; 43% of total eggs laid produced fledged young.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common throughout Indus plains of Pakistan, and fairly common in Dera Ismail Khan district, in N. Fairly common in Nepal. Uncommon in Bhutan, where found primarily in W foothills, but relatively common in Phuntsholing area. Common and widespread in India, and abundant in Rajasthan, Uttar Pradesh and Uttarakhand Pradesh, present ("seen quite regularly") in Rajaji National Park and common in Dudhwa National Park, both in Uttar Pradesh, common in Kaizer Wildlife Sanctuary, in Haryana, abundant on New Forest campus at Dehra Dun and common in Dehra Dun valley, in Uttarakhand, and common in Bhitarkanika Wildlife Sanctuary, in Orissa; present in Buxa Tiger Reserve, in West Bengal, with 5 birds/km<sup>2</sup> in monoculture plantation and 152.2 birds/km<sup>2</sup> in scrub; present in Mudumalai National Park, in Tamil Nadu. Common in Bangladesh.

**Bibliography.** Acharya (1951), Ali & Ripley (1971), Ali *et al.* (1996), Allen *et al.* (1997), Andrews & Naik (1965, 1966, 1972), Barua & Sarmah (2005), Bhattacharyya (1997), David & Gosselin (2002b), Devashayam & Devashayam (1991), Gaston (1976a, 1977, 1978a, 1978b), Gaston & Zacharias (2000), Gaston *et al.* (1979), Gokula & Vijayan (1997), Grimmett *et al.* (1998), Gupta & Mishra (1997), Hume & Oates (1889), Inskipp & Inskipp (1991, 1993b), Janki Rama Rao *et al.* (1980), Javed & Rahman (1998), Kato (1988), Kytinpa (2000).

cellaneous high-pitched notes also given. Calls (by single bird) include high-pitched rapid oscillating chirring, with several notes on one pitch punctuated by stronger, higher-pitched note, "t'it't'it't'it'h'i'h'i,t'it't'it't'it'h'i..."; also given with flock calls. In first alarm a "keek", followed by low soft repeated "kurrr" if intruder persists; and a loud high whistle when fighting or mobbing. Twittering "kikikiki" when separated from group, and loud whining when in distress, summoning other birds; short low "ke" while foraging or preening, used for contact, and low "kekeke" prior to leaving area.

**Habitat.** Open forest and secondary woodland, dry scrub, particularly *Lantana*, cultivation, village precincts, orchards, urban gardens and compounds; in drier, more open areas than those favoured by *T. striata*, although commonly syntopic with latter. Up to 300 m, exceptionally 1000 m, in India; to 1700 m, exceptionally 2100 m, in Sri Lanka.

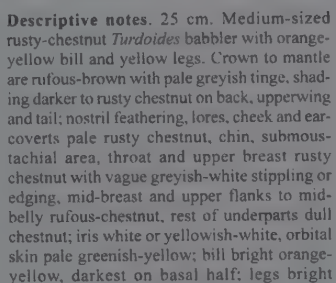

**Food and Feeding.** Insects such as beetles (Coleoptera), grasshoppers (Orthoptera), cicadas (Cicadidae) and other bugs, caterpillars, termites (Isoptera), also spiders (Araneae); also wild figs (*Ficus*), *Ziziphus* and *Lantana* berries, grain, nectar (including that of *Erythrina* and *Butea*), and scraps around habitations. Rarely, whispicoptons (Amblypygi) and even lizards, including garden fence lizard (*Calotes versicolor*). Forages mainly on ground, but occasionally flycatches; often leaps vertically to snatch food item, and gleams from leaves and branches, sometimes while hanging upside-down. In groups; occasionally associates with *T. striata* and *T. rufescens* where ranges overlap.

**Breeding.** All year, mainly Mar–Nov, in India; mainly Nov–Mar in low-country dry zone of Sri Lanka. Co-operative breeder, living in social group of 3–14 individuals with home range 5.3–9.3 ha. Nest, built by both sexes, a loose cup, made of small twigs, rootlets, coarse grasses, green weeds, leaves and old newspaper, lined with fine grasses, fern stems or rootlets, placed 1.2–6 m or higher above ground in thorn bush, hedge, small tree or brambles. Clutch 2–5 eggs, usually 3–4, deep greenish-blue (normally deeper in colour than those of *T. striata* and *T. malcolmi*); incubation period 14–17 days; nestlings fed by both sexes, nestling period c. 14 days; fledglings fed by other flock-members, as well as by parents. Frequent brood parasitism by Jacobin Cuckoo (*Clamator jacobinus*) reported. Of 150 eggs in 82 nests in one study, eight failed to hatch; 42% of total eggs resulted in fledged young.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Locally common in India; common through-

out Sri Lanka except on highest hills. In India, present in Mudumalai National Park and common at Point Calimere, in Tamil Nadu; at Sivakasi, in S India, density was measured at 55 birds/km<sup>2</sup>, but area studied was only 0.2 km<sup>2</sup>; in surveys in 1973–1997 in Western Ghats, found in six areas, including two protected areas, namely Silent Valley and Parambikulam.

undescribed. Voice. In groups, gives constant  
retulant, short, sharply downturned "tscheurk",  
sometimes drawn out into a short trill. Call notes  
"kraa-kraa-kraa" also described; gives other less

bamboo scrub in well-wooded areas; apparently sometimes found in selectively logged forest or up to 2100 m.

black beetles (Coleoptera); also fruit. Gregarious up to 50–60 individuals (mean in one study) and often a primary component. Forages in understorey, gleaning from leaves and working

sses, small twigs and leaves, placed in low fork trunk. Clutch 2-3 eggs, deep greenish-blue. No

ed. Currently considered Near-threatened. Relatively common to common in wet lowlands, but uncommon above 700 m. Common in Sinharaja Forest Reserve and fragmentation in recent decades owing to agriculture, shifting cultivation, fire, urban growth. Distribution is relatively restricted.

art & Stattersfield (2004), Collar *et al.* (2001), Grimmer (1889), Jayasekara *et al.* (2003), Kotagama & Fernando (1978), Rasmussen & Anderton (2005), Stattersfield

*Turdoides melanops*

**French:** Cratérope masqué **German:** Schwarzgesichtdrossling **Spanish:** Turdoide Enmascarado  
**Other common names:** Black-faced Babbler

**Taxonomy.** *Crateropus melanops* Hartlaub, 1867, Damaraland, Namibia.

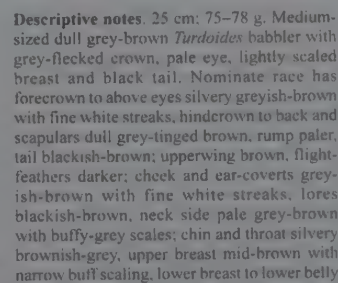

Formerly thought possibly to form a superspecies, and even perhaps to be conspecific, with *T. tenebrosa* and *T. reinwardtii*. Alternatively suggested as part of a superspecies with *T. sharpei*, *T. leucopygia*, and *T. hartlaubii*. Often treated as conspecific with *T. sharpei*. Three subspecies recognized.

**Subspecies and Distribution.**

*T. m. angolensis* A. A. da B. Pinto, 1967 – SW Angola (Huila, E. Namibe).

*T. m. melanops* (Harlaub, 1867) – S Angola and N Namibia.

*T. m. querula* Clancey, 1979 - SE Angola, NW Botswana and NE Namibia (Caprivi), also, disjunctly, extreme W Zimbabwe.

flanks, thighs and vent plainer and darker; iris  
all black; legs slaty black. Sexes similar. Juveniles  
brown iris. Race *angelensis* is shorter-billed than  
*pyrrula* is smaller, darker and greyer, darker-faced,  
parts. VOICE. Chorus song a nasal chattering  
or faster "papapapapapapapapa", all rising to a  
aaaaaaa "yells, bleating squeaks, low "juk" and  
quiet "cull" every 2-3 seconds.

Secondary growth in understorey of dense *Acacia* and  
(*Baikiaea plurijuga*) or purple-pod (*Terminalia*)  
talls tall under high canopy; also dry bush, riverine  
and *Brachystegia* woodland, and camelthorn wood-  
land. At relatively low elevations.

all groups of 5-7 individuals, occasionally up to 15

Mar in Namibia. Co-operative breeder, with up to 10 eggs. Nest lined with finer fibres, placed 1.5–5 m above ground. Clutch? 3 eggs, deep greyish-turquoise. No

4. Uncommon to locally common. Common along  
Karas National Park, in Namibia, uncommon to

*Turdoides affinis*

**French:** Cratélope affin    **German:** Gelbschnabeldrossling    **Spanish:** Turdoide Piquigualdo  
**Other common names:** White-headed Babbler

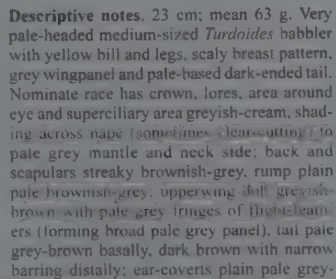

**Taxonomy** *Malacocircus*]. *affinis* Jerdon, 1845, Travancore, India.

Two subspecies recognized.

**Subspecies and Distribution.**

*T. a. affinis* (Jerdon, 1845) – S peninsular India (including Rameswaram I) S from S Maharashtra and SE Madhya Pradesh.

*T. a. taprobanus* Ripley, 1958 – Sri Lanka.

ra, throat and breast dull brown with broad pale  
lower breast and continuing onto plain buff  
pale buff-grey; iris creamy or greyish-white to  
r. Juvenile has less distinct streaks above and  
r. greyer wash than nominate on head and upper

time, fading and flaring up again. Isolated, mis-

**Bibliography.** Brewster (1986), Britton (1980), Clancey (1979, 1985), David & Gosselin (2002b), Dean (2000), Fry *et al.* (2000), Ginn *et al.* (1989), Hall & Moreau (1970), Harrison *et al.* (1997), Hockey *et al.* (2005), Penny (1994), Shaw (2001a), Traylor (1965).

## 176. Sharpe's Babbler

### *Turdoides sharpei*

**French:** Cratérope de Sharpe **German:** Schwarzzügeldrossling **Spanish:** Turdoide de Sharpe  
**Other common names:** Sharpe's Pied Babbler

**Taxonomy.** *Crateropus sharpei* Reichenow, 1891, Kakoma, south-west Tanzania. May form a superspecies with *T. squamulata* and *T. hypoleuca*, possibly including also *T. hindei*. Alternatively suggested as part of a superspecies with *T. melanops*, *T. leucopygia* and *T. hartlaubii*. Often treated as conspecific with *T. melanops*. Proposed race *clamosus* (Rift Valley in Kenya) merged with nominate. Two subspecies recognized.

#### Subspecies and Distribution.

*T. s. sharpei* (Reichenow, 1891) – extreme E DR Congo, Rwanda, Burundi, Uganda (except N), SW Kenya and NW & W Tanzania.

*T. s. vepres* R. Meinertzhagen, 1937 – Nanyuki area, on slopes of Mt Kenya (C Kenya).

**Descriptive notes.** 24–26 cm; 66–91 g. Resembles *T. melanops*, but bill shorter, body more streaked, tail not so dark, and underparts with no buff tones; wary. Nominative race has crown, upperparts and upperwing greyish-brown, crown to scapulars lightly scaled or mottled grey (particularly on nape), tail dusky brown; lores to front half of eye blackish-brown, head side plain greyish-brown or pale-mottled dark brown; chin and submoustachial area to breast mouse-grey with pale creamy-grey scales and usually fine brown streaks, belly to vent pale greyish-brown with vague streaking, lower underparts more uniform; iris

silvery white or creamy white; bill black; legs dark slaty brown. Sexes similar. Juvenile lacks paler tips on head and neck, has throat and breast less scaly, iris greyer or browner. Race *vepres* is darker than nominate, with variable creamy white on chin and throat, lower belly often creamy white. **Voice.** Chorus song a babbling “chookááh-chookááh-chookááh...”, having slightly insane and hilarious laughing quality. Calls loud and harsh: contact a high grating “skaaa” or long, downslurring “skaaayaaa” or “nee-yeah”; also has nasal “pa-pa-pa”, sometimes combined into chatter of same petulant quality, a hoarse nasal “wha-u”, and in alarm a cat-like “nyaaa”.

**Habitat.** Forest-edge thickets and scrub, wooded plains and acacia savanna, dense bushland, riverine woodland, elephant grass, gardens; where sympatric with *T. plebejus*, appears to prefer more open areas. Found at up to 2425 m; 1000–2200 m in Kenya, but chiefly 1500–1900 m.

**Food and Feeding.** Mainly invertebrates, also small reptiles and small fruits. Forages in trees (higher up than *T. plebejus*), tall grass and shrubby, coming on to lawns to probe for insects and bounding after termites (Isoptera); creeps about near ground. Usually in parties of 2–10, mainly 4–5 individuals, occasionally in company with other babbler species; also sometimes with *Lamprolaima* glossy starlings, Crested Francolins (*Francolinus sephaena*) and ground-foraging Nubian Woodpeckers (*Campethera nubicola*), wood-hoopoes (*Phoeniculus*) and Crowned Hornbills (*Tockus alboterminatus*).

**Breeding.** Apr–Sept (peak Apr–May) in Uganda, Mar–Dec in Kenya and Mar–Jun in Tanzania. Co-operative breeder. Nest a rather untidy cup made of roots and creeper stems, twigs and grass stems, lined with fine grass roots, creeper stems or other softer materials, placed in dense bush or large isolated bush covered with dead creepers. Clutch 2–3 eggs, dark blue or greenish-blue; nestlings attended and fed by all members of group. No information on incubation and nesting periods. Aggressive towards Levaillant's Cuckoo (*Clamator levaillantii*), which presumably parasitizes nests of present species.

**Movements.** Resident. Recorded in all months in Kampala region of Uganda, but sometimes unaccountably absent for weeks or months.

**Status and Conservation.** Not globally threatened. Locally common in DR Congo; widespread in Rwanda and Burundi; widespread also in Uganda, where present in Murchison Falls National Park; locally common in Kenya, although now vanished from Kikuyu and Mt Nyiru; widespread in Tanzania W of 33° E, with old records from Serengeti National Park.

**Bibliography.** Brown & Britton (1980), Carswell *et al.* (2005), Chapin (1953), Clancey (1985), Fry *et al.* (2000), Jackson & Selater (1938), Lewis & Pomeroy (1989), Schmidt (1982), Short & Horne (2006), Stevenson & Fanshawe (2002), Zimmerman *et al.* (1996).

## 177. Dusky Babbler

### *Turdoides tenebrosa*

**French:** Cratérope ombré **German:** Uferdrossling **Spanish:** Turdoide Sombrio

**Taxonomy.** *Crateropus tenebrosus* Hartlaub, 1883, Kudurma (4°45' N, 29°35' E), Sudan. Has been thought possibly to form a superspecies, and even perhaps to be conspecific, with *T. melanops* and *T. reinwardtii*. Monotypic.

**Distribution.** NE Central African Republic, SW, S & SE Sudan, SW Ethiopia, NE DR Congo and NW Uganda.

**Descriptive notes.** 24–26 cm. Dark, medium-sized *Turdoides* babbler with longish bill, white eye, blackish lores, wings and tail, and pale-scaled blackish-brown breast. Forehead is silvery greyish-brown, shading to dark olivaceous brown on crown and upperparts; upperwing and tail blackish-bronzy brown; lores blackish, ear-coverts greyish olive-brown, cheek and neck side olive-brown; chin, submoustachial area, throat and upper breast blackish-brown with pale olive-grey scaling, latter dominating around chin; lower breast and belly centre dull olivaceous greyish-brown, belly side, thighs and vent warm dull olive-brown; iris yellow-

ish-white; bill black; legs dull dark brown. Sexes similar. Juvenile is rather paler above than adult, wings and tail warmer and browner, throat and breast grey with faint streaks (lacking scaly appearance), much browner on belly, iris pale greyish-yellow. **Voice.** Chorus song not reported, and voice little known. Call an occasional hoarse “chow”, with louder, repeated nasal “what-cow” from male.

**Habitat.** Undergrowth of hilly woodlands and other dense cover near water, at 600–1200 m.

**Food and Feeding.** Invertebrates, including beetle larvae (Coleoptera), small snails, small millipedes (Diplopoda); also fruit. Found in pairs or small parties; shy and secretive.

**Breeding.** Apr and Jul in Sudan, Feb–Apr and Jun in Uganda and Dec in DR Congo. Nest a fairly deep cup made of dried leaves and grasses, lined with rootlets, like that of *T. melanops* but less bulky, and usually placed 1–2 m up in thick cover with creepers. Clutch 2–3 eggs, very glossy pale blue. No other information.

#### Movements. Resident.

**Status and Conservation.** Not globally threatened. Present but uncommon in Manovo-Gounda-Saint Floris National Park, in Central African Republic; rare in Sudan, but possibly locally common in far S & SE; frequent in SW Ethiopia; fairly common at Faradje, in DR Congo; present in Mount Kei White Rhino Sanctuary, in Uganda.

**Bibliography.** Borrow & Demey (2001), Britton (1980), Brown & Britton (1980), Carswell *et al.* (2005), Cave & Macdonald (1955), Chapin (1953), David & Gosselin (2002b), Fry *et al.* (2000), Hall & Moreau (1970), Nikolaus (1987), Stevenson & Fanshawe (2002), Urban & Brown (1971).

## 178. Reinwardt's Babbler

### *Turdoides reinwardtii*

**French:** Cratérope à tête noire **German:** Weißaugendrossling **Spanish:** Turdoide Cabecinegro  
**Other common names:** Blackcap/Black-eyed Babbler

**Taxonomy.** *Crateropus Reinwardtii* [sic] Swainson, 1831, “Indian Islands”; error = Senegal. Has been thought possibly to form a superspecies, and even perhaps to be conspecific, with *T. melanops* and *T. tenebrosa*. Two subspecies recognized.

#### Subspecies and Distribution.

*T. r. reinwardtii* (Swainson, 1831) – Senegal E to Mali and Sierra Leone.

*T. r. stictilaema* (Alexander, 1901) – N Ivory Coast, S Burkina Faso and Ghana E to Cameroon, S Chad, WC & S Central African Republic and extreme N DR Congo.

**Descriptive notes.** 25–26 cm; 69–91 g. Fairly large *Turdoides* babbler, tail not particularly long, with solid blackish hood, plain grey-brown upperparts and spotted breast. Nominative race has lores, crown, ear-coverts, cheek and submoustachial area brownish-black, neck side and mantle to rump olive-tinged pale grey-brown, upperwing and tail dark brown; chin and throat dirty white, upper breast pale greyish-buff with dusky-brown narrow streaking and mottling, lower breast plain or plainer greyish-buff, belly to vent pale buffy brown, creamier on mid-belly; iris straw-yellow to creamy white; bill greenish-black; legs sepia

to brownish-grey. Sexes similar. Juvenile has forehead and face dark brown, reduced mottling below, and bill pale-tipped. Race *stictilaema* has darker and greyer underparts than nominate, throat greyish with narrow blackish streaks and mottling extending up from breast. **Voice.** Chorus song involves accelerating and crescendoing single, scraping “jaaaaaaaa” or double “gwaááá-ga” notes, raspy and chattering, punctuated with staccato “cha-ka-ta” or “ko-kwee”. Calls include continuous grating “ja-ja-ja-ja...” or lower, faster, almost trilling “jaagagagagaga”, used in contact; a loud braying, descending “waaa... haa-haa-haa-haa”; and various short harsh grating notes, e.g. “dzwit”, “dzwuk-dzwuk-dzwuk”, “jwiu”, “jut”.

**Habitat.** Gallery forest, thick clumps of riverine vegetation in open savanna woodland, swampside thickets, bamboo groves, tall scrub and rank grass along streams, parkland, sometimes mangroves; from sea-level in many areas, to c. 1000 m in Cameroon. In denser cover than that favoured by *T. plebejus*.

**Food and Feeding.** Insects and berries found in stomachs. Forages on ground among fallen leaves and debris under tangled vegetation, also among dead banana leaves, etc. Flips litter with bill. Found in small flocks of six or so, sometimes ten, individuals, even when breeding.

**Breeding.** Nov–Dec in Gambia, Jan in Senegal, Sept–Jan in Sierra Leone and Nov–Jul in Mali; fledged dependent young in Jan in Ghana; Jun–Jul and Nov–Dec in Nigeria. Co-operative breeder. Nest a large open cup made of leaves, a few twigs and tendrils, scantily lined with roots and tendrils, placed 1.5 m or more up in head of small oil palm (*Elais*), palm-stump fronds or heavily foliated tree. Clutch 2–3 eggs, dark sky-blue (much darker than blue variety of *T. plebejus*). No other information.

#### Movements. Resident.

**Status and Conservation.** Not globally threatened. Uncommon to locally common across range. Fairly common and widespread in Gambia, S Senegal, Guinea-Bissau and Guinea, less so in Sierra Leone; widespread in Boucle du Baoulé National Park, in Mali; uncommon in Arli National Park, in Burkina Faso, but frequent around Ouagadougou; uncommon in Ivory Coast except in two areas, one being N Comoé National Park; fairly common and widespread yet patchy in Ghana; common in Togo. Presumed to be widespread in appropriate habitat in N Cameroon; fairly common in S Chad. Present in Dzanga-Ndoki National Park, in Central African Republic.

**Bibliography.** Bannerman (1953), Barlow *et al.* (1997), Borrow & Demey (2001), Chapin (1953), Cheke & Walsh (1996), David & Gosselin (2002b), Demey & Fishpool (1991), Elgood *et al.* (1994), Fry *et al.* (2000), Gore (1990), Green & Carroll (1991), Grimes (1987), Hall & Moreau (1970), Louette (1981), Morel & Morel (1990), Serie (1950a, 1950b, 1957, 1965).

## 179. Brown Babbler

### *Turdoides plebejus*

**French:** Cratérope brun **German:** Sudandrossling **Spanish:** Turdoide Pardo  
**Other common names:** Sudan (Brown) Babbler

**Taxonomy.** *Icos plebejus* (Cretzschmar, 1828, Kordofan Province, Sudan. Considered to form a superspecies with *T. leucocephala* and *T. jordanii*; sometimes treated as conspecific with former. Proposed race *namensis* (Cameroon and adjacent W Central African Republic) synonymized with *cinerea*. Three subspecies recognized.

**Subspecies and Distribution.**

*T. p. platycirca* (Swainson, 1837) – S Mauritania and Senegal E to SE Mali, SW Niger border area and W Nigeria.

*T. p. plebejus* (Cretzschmar, 1828) – NE Nigeria E to C & S Sudan.

*T. p. cinerea* (Heuglin, 1856) – SE Nigeria E to S Sudan and SW Ethiopia, S to Cameroon, NE DR Congo, Uganda and W Kenya.

**Descriptive notes.** 22–25 cm; 52–80 g (laying female 88 g). Medium-sized greyish-brown *Turdoides* babbler with black bill, streaky crown, and white-chevroned throat and breast. Nominative race has head scaly grey-brown with blackish dagger-shaped streaks, upperparts mousy grey-brown with paler edges and vague dark streaks, upperwing and tail bronzy brown; lores and area around eye whitish, ear-coverts vaguely streaky greyish-white; upper submoustachial area and chin whitish, throat, lower moustachial area and breast paler grey-brown with subterminal blackish streaks and terminal white tips (giving speckled appearance), belly whitish, flanks, thighs and vent brownish-grey; iris yellow; bill black; legs dusky or slaty black. Sexes similar. Juvenile is plainer and more tawny-brown than adult, particularly on wings and tail, with brown iris. Race *platycirca* has darker crown, greyer face, and chin to breast with less contrasting speckled pattern than nominate; *cinerea* is smaller and darker, with scalier breast pattern. **VOICE.** Song in chorus described as an irritable chuckling, in bursts lasting 5–10 seconds and involving variety of grating babbling cries, “jeeya-jwor jeeya-jwor jeeya-jwor”, “gworrr gworr”, “jeew jeew jeew”, and including chattering like that of a wood-hoopoe (*Phoeniculus*); described also as very loud raucous wooden-sounding chatter, breaking into scolding “k-tchah k-tchah k-tchah...”. Usual contact call a twangy “caa” or “ciau”; harsh reiterated “chuck” repeated for 3–4 seconds in mild anxiety; alarm a harsh chatter reminiscent of that of Mistle Thrush (*Turdus viscivorus*); scolding call a repeated buzzy “chay-o”.

**Habitat.** Open savanna woodland, particularly with *Lophira alata*, parkland, denser parts of open savanna, wooded grassland, bush country scattered with acacias, light forest edge, gallery forest, riparian thickets in drier country, overgrown cultivation, elephant grass (*Pennisetum purpureum*), farmland, parks and gardens; often in rocky areas such as bases of inselbergs where dense scrub grows, and in cold bleak habitats in W Kenya reaches 2300 m; to 1700 m in Uganda.

**Food and Feeding.** Ants (Formicidae), beetles (Coleoptera), mantids, termites (Isoptera), inchworms and, in beeswax, wax-moth larvae; also beeswax itself, berries of *Carissa edulis*, mangoes, papaya and apparently dates of *Phoenix dactylifera*. Opportunistic, taking (e.g.) meat and suet from carcasses hung up in meat sheds. Forages on ground under bushes, scuffling in leaf litter in short hops, bounding strongly when necessary, and moving out on to bare ground, keeping close to cover; glances, pecks, probes and lifts leaves to look underneath them; uses a scythe-like motion of bill in seeking insect prey in drying beeswax. Found in tight-knit family parties of 3–14 individuals, usually 6–8; some pair off during breeding season. Retiring and skulking, yet surreptitiously inquisitive and often noisy. Frequently feeds in mixed-species flocks with diverse birds, and accompanies dwarf mongoose (*Helogale parvula*) parties; chief association with *T. rubiginosa* (in E of range).

**Breeding.** Apr and Aug in Mauritania; Jun, Aug–Oct and Dec–Jan in Gambia; Mar–Jun and Aug in Sierra Leone; Apr–May, Jul and Nov in Ghana; Jun–Jul in Niger; almost all months in Nigeria, specifically Sept–May in N and Dec–Feb and Apr in S; Nov–Jan and Aug–Sept in Sudan; Nov–Mar in DR Congo; nest-building in Jan and eggs Apr in Uganda; Apr–Sept (mostly May–Aug) and Nov–Jan in C Kenya. Co-operative breeder; mating system unknown, but evidence suggests that two females often lay in one nest. Nest a large, fairly shallow cup made of rootlets, grasses, straw, sticks and leaves, lined with rootlets, fine grasses or other fine materials, placed 0.75–5.5 m up in thick (usually thorny) bush, low shrub, creeper-clad acacia or a small tree (*Tarchonanthus*, *Euclea*, *Rhus*, *Carissa*, *Olea*); once in deserted nest of Senegal Coucal (*Centropus senegalensis*). Clutch 2–4 eggs (usually 3 in W Africa), deep greenish-blue to bright salmon-pink, pale mauve or mauvish to grey-blue (colour varying both between and within clutches); no information on incubation and nestling periods; chicks leave nest early. Nests parasitized by Levaillant’s Cuckoo (*Clamator levaillantii*) in Sudan and W Africa; probably also E Africa, where groups seem to chase this species.

**Movements.** Mostly resident; some seasonal movement. In C Burkina Faso noted more often in wet season than in dry, suggesting some local rains-related displacements; in Kampala region of Uganda makes local movements, often being erratically absent for weeks or months.

**Status and Conservation.** Not globally threatened. Fairly common to common across range. Widespread and patchily common in Senegal, and common throughout Gambia; present and common in Boucle du Baoulé National Park, in Mali, and fairly common in sahel zone in E Burkina Faso. Widespread in N Ivory Coast, and widespread but local in Ghana: common throughout Togo and Benin. Common throughout savanna zone in Nigeria, commonest towards Niger border; present in Parc du “W”, in Niger. Common in S Sudan in low-lying areas. Frequent to locally common in Ethiopia, Uganda and Kenya. In Uganda, common in gardens and parks in Kampala.

**Bibliography.** Bannerman (1951, 1953), Barlow *et al.* (1997), Borrow & Demei (2001), Britton (1980), Butynski & Kalina (1993), Carswell *et al.* (2005), Cave & Macdonald (1955), Chapin (1953), Cheke & Walsh (1996), David & Gosselin (2002b), Elgood *et al.* (1994), Fry *et al.* (2000), Giraudoux *et al.* (1988), Gore (1990), Grimes (1987), Hall & Moreau (1970), Jackson & Selater (1938), Lewis & Pomeroy (1989), Louette (1981), Moore (1984), Morel & Morel (1990), Nikolaus (1987), Serle (1938, 1957, 1977), Short & Horne (2006), Stevenson & Fanshawe (2002), Urban & Brown (1971), Vestergaard & Kirkeby (1980), Wilson & Wilson (1994), Zimmerman *et al.* (1996)

## 180. White-headed Babbler

### *Turdoides leucocephala*

**French:** Cratérope à tête blanche **German:** Weißkopfdrossling **Spanish:** Turdoide Cabeciblanco  
**Other common names:** Cretzschmar’s Babbler

**Taxonomy.** *Turdoides leucocephala* Cretzschmar, 1826, Sennar = Blue Nile Province, Sudan. Considered to form a superspecies with *T. plebejus* and *T. jardineii*; sometimes treated as conspecific with one or other. Monotypic.

**Distribution.** E Sudan, NW Ethiopia and NW Eritrea.

**Descriptive notes.** 22–25 cm. Medium-sized greyish-brown *Turdoides* babbler with white head and black bill. Head and chin are off-white, cleanly defined from nape and throat, but with blackish bare skin from lores to around and behind eye, and ear-coverts appearing greyer owing to thinness of white feathers over black skin; plain pale greyish-brown upperparts, slightly paler on rump, upperwing and tail brown, tail darker distally; neck side grey-brown, throat and upper breast grey-

**Food and Feeding.** Only “insects” reported. Lives in parties of 5–6 individuals, occasionally up to twelve together.

**Breeding.** May–Jun in Ethiopia. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon to fairly common in Sudan; frequent in Ethiopia and Eritrea.

**Bibliography.** Cave & Macdonald (1955), Cheesman & Selater (1935), Cretzschmar (1826), David & Gosselin (2002b), Fry *et al.* (2000), Hall & Moreau (1970), Mackworth-Praed & Grant (1960), Neumann (1904), Nikolaus (1987), Reichenow (1905), Urban & Brown (1971), Witherby (1901).

## 181. Arrow-marked Babbler

### *Turdoides jardineii*

**French:** Cratérope fléché **German:** Braundrossling **Spanish:** Turdoide de Jardine  
**Other common names:** Arrow/Jardine’s Babbler

**Taxonomy.** *Crateropus Jardineii* A. Smith, 1836, banks of rivers beyond Kurrichane, north-western Transvaal, South Africa.

Considered to form a superspecies with *T. plebejus* and *T. leucocephala*; sometimes treated as conspecific with latter. Race *convergens* sometimes subsumed in nominate. Proposed race *kikuyuensis* (SW Kenya and adjacent N Tanzania) merged with *emini*, and *natalensis* (S Mozambique S to Lesotho) included in nominate. Seven subspecies recognized.

**Subspecies and Distribution.**

*T. j. hyposticta* (Cabanis & Reichenow, 1877) – S Gabon, S PR Congo, SW DR Congo and NW Angola.

*T. j. emini* (Neumann, 1904) – SW & S Uganda and SW Kenya S to E DR Congo and NW & N Tanzania.

*T. j. tanganyicae* (Reichenow, 1886) – SE DR Congo and NC & NE Zambia.

*T. j. kirkii* (Sharpe, 1876) – SE Kenya, C, E & SE Tanzania, NE (E part) Zambia, Malawi and N & C Mozambique.

*T. j. tamalakani* Meyer de Schauensee, 1932 – WC & S Angola E to extreme SW Zambia, NE Namibia and N Botswana.

*T. j. convergens* Clancey, 1958 – N & E Botswana, Zimbabwe (except far N), C Mozambique and coastal NE South Africa.

*T. j. jardineii* (A. Smith, 1836) – SE Botswana E to S Mozambique, S to N & NE South Africa, Swaziland and NE Lesotho.

**Descriptive notes.** 22–25 cm; 56–85 g. Medium-sized *Turdoides* babbler, dull brownish-grey above, paler below, with distinctive pointed white tips of throat and breast feathers. Nominative race has narrow pointed crown feathers with brownish-black dagger-shaped centres and dull grey-buff edges, shifting to whitish-tipped soft-edged brown and grey-buff feathering on neck side and upperparts, paler and plainer rump, dark brown upperwing and blackish-brown tail; feathers on superciliary area slightly whiter than on crown, lores blackish, ear-coverts, cheek and submoustachial area greyish-brown with narrow white tips; chin to

upper belly brownish-ashy with elongate pointed (spike-like) white tips, lower belly buffish with barely noticeable white shaft streaks; iris scarlet to crimson, inner ring orange to bright yellow (sometimes reversed); bill black; legs brown to dark slate. Sexes similar. Juvenile is much plainer than adult, with no arrow-shaped marks on chest, iris dark brown. Race *hyposticta* is small and grey-headed, with greatly reduced white tips of breast feathers; *tanganyicae* has rather plain blackish crown and face well demarcated from rufescent-tinged plain olive-brown upperparts, underparts as nominate but breast less grey (more concolorous with lower underparts), white tips much narrower and vaguely yellowish-tinged; *emini* is like nominate, but feathers of head overall blacker, head side browner, underparts as previous but shape of tips mid-way towards nominate; *kirkii* is like last, but browner above, notably on neck side, crown feathers less pointed and less black, breast greyer (not so much as in nominate) and arrow marks whiter and narrower; *tamakani* resembles previous, but greyer above, lower underparts colder brown; *convergens* is more buffy olive below than nominate, more streaked on flanks and vent. **VOICE.** Chorus song a harsh nasal chatter, “ra-ra-ra-ra-ra” or “scurr-urr-urr-urr-urr-urr”, usually begun by 1–2 birds calling softly, taken up by others and rising to grating, whirring crescendo and dying away, often a few birds giving low conversational “kuk” and “jigga” notes before new chorus begins. Also a harsh “chak-chak-chak” and “kaa-kaa-kaa” like distant call of Rook (*Corvus frugilegus*); loud “chow-chow-chow-chow...”, often by several birds together.

**Habitat.** Dense thickets in higher-rainfall bush and tree savanna, open woodland underbrush, dry riverine forest edge and reedbeds, bush clumps on termittaria, thorny brush on rocky ground with rank grass, abandoned cultivation in woodland, regenerating bushy growth at edges of cultivation, overgrown abandoned fields, exotic plantations; in N South Africa habitat dominated by tamboti (*Sporobolus africanus*) on sparse grass, or by acacias on extensive grass cover; in Zimbabwe found in open soft woodland with bushes, shrubs and secondary growth, often along watercourses. Occurs at up to 1675 m, occasionally 1830 m; to 2315 m in Rwanda, 2050 m in Malawi.

**Food and Feeding.** Mostly invertebrates up to 35 mm long, including termites (Isoptera), ants (Formicidae), bush-crickets and grasshoppers (Orthoptera), moths and caterpillars (Lepidoptera), beetles (Coleoptera), dipteran flies and their larvae (including tsetse fly) and grubs, also spiders

and sun-spiders (Solitugae), and snails; also lizards; also seeds, fruit including loquats (*Eriobotrya japonica*) and palm nuts (*Elaeis guineensis*), and nectar (e.g. of *Aloe*). Larger food items such as certain fruits are held in foot while being eaten. Recorded as coming to garden birdtable, apparently for seeds. Nestlings fed mainly with insects: of 148 food items, 28% grasshoppers, 20% caterpillars. Forages on ground and in lower bushes and undergrowth, fossicking in leaf litter and creeping through lower branches. Usually in parties of 4–8 individuals, range 3–15 (mean 6), even during breeding season. May form mixed parties with *T. hartlaubii* where ranges overlap; in Mozambique often associates with Terrestrial Brownbul (*Phyllastrephus terrestris*).

**Breeding.** Mar–May and Aug–Oct in Uganda; mainly Sept–May in Tanzania and Zambia; Sept–Jul (mainly Oct) in Malawi and Sept–Dec in Mozambique; in all months (mainly Sept–Nov) in Zimbabwe, May–Aug–Sept and Nov–Dec in Angola and Oct–Mar (mainly Nov–Jan) in Botswana; Oct–Mar in KwaZulu-Natal, and in all months (peak Sept–Apr) elsewhere in South Africa; groups make two or three nesting attempts per breeding season. Co-operative breeder, but not known if more than one female provides clutch; at one site in South Africa, territories averaged 37 ha (range 10.5–63.5 ha), larger groups defending larger areas. Nest, built by all group members, a bulky open bowl made of dry flower stems, coarse grass, pieces of reed, roots, twigs, dead or decayed leaves and leaf fronds, lined with fibres, rootlets and tendons, placed 0.5–7 m up in tree, hedge, floian in overhanging branches along rivers, reed tangle, thick bush, creeper tangle around dead stump or tree cavity; old nest of another species sometimes used; new nest built for each breeding attempt. Clutch 2–8 eggs (usually 3), glossy pale greenish-blue or deep turquoise-blue; incubation by all members of group, period variable, 13–17 days; chicks fed by parents and helpers, immature helpers tending to provide less feeding, nestling period 18–21 days (shortest when group larger). Significant brood parasitism (7.8% of nests) by Levaiant's Cuckoo (*Clamator levaillantii*). Of 13 nests, only three successful; only 8 of 44 eggs resulted in fledging success (uncorrelated with group or territory size).

**Movements.** Resident; some local displacements. In Uganda, recorded only Jun–Aug in W Nile region; occasional vagrancy reported, e.g. W to R Cunene, in NW Namibia.

**Status and Conservation.** Not globally threatened. Locally common over much of range, and adaptable to habitats partly influenced by man. Often common in Uganda, where present in Bwindi Impenetrable Forest National Park and Kyambura Wildlife Reserve; locally common in SW Kenya. Uncommon and local in S Gabon and PR Congo; widespread but often uncommon in savannas of S DR Congo; common and widespread in Zambia and in Malawi (in latter common below 1700 m). Common and widespread in Sul do Save, in Mozambique, where national population estimated at more than 20,000 individuals. Fairly common to locally very common in Botswana; common and widespread in Zimbabwe below 1300 m. Common and widespread in NE South Africa, where density in broadleaf *Burkea africana* woodland in Limpopo Province 8 birds/km<sup>2</sup>, and common in Kruger National Park.

**Bibliography.** Backshall (1993), Barry (1998), Benson (1953), Benson & Benson (1977), Benson & Irwin (1967), Benson & White (1957), Benson *et al.* (1971), Borrow & Demey (2001), Britton (1980), Brown (1969), Brown & Britton (1980), Carswell *et al.* (2005), Chapin (1953), Clancey (1971, 1996b), Clark & Clarke (1985), Cooper, J. ## 182. Scaly Babbler

### *Turdoides squamulata*

**French:** Cratérope maillé **German:** Schwarzkopfdrossling **Spanish:** Turdoide Escamado  
**Other common names:** Dark-billed Scaly Babbler, Squamulated Babbler

**Taxonomy.** *Crateropus squamulatus* Shelley, 1884, Mombasa, Kenya.

Has been thought to form a superspecies with *T. sharpei* and *T. hypoleuca*, possibly including also *T. himdei*. Birds from R Webbe Gestro, in S Ethiopia, thought to represent an undescribed race, and those from S Ethiopia–NE Kenya border region (Lak Bor watercourse, R Daua) another such; in each case, however, the possibility of hybrid origin evidently not yet excluded (R Webbe Gestro birds uniform brown above, brownish-white below, iris red; Lak Bor birds intermediate between *jubaensis* and *caroliniae* in extent of white on head). Three subspecies currently recognized.

#### Subspecies and Distribution.

*T. s. caroliniae* Ash, 1981 – SE Ethiopia and adjacent SC Somalia (R Shabeelle).

*T. s. jubaensis* van Someren, 1931 – S Ethiopia and adjacent S Somalia (R Jubba).

*T. s. squamulata* (Shelley, 1884) – extreme S Somalia, SE Kenya and adjacent NE Tanzania.

**Descriptive notes.** 22–23 cm; 55–85 g. Smallish *Turdoides* babbler with grey-scaled blackish head and white-scaled greyish breast, orange eye. Male of nominate race has crown brownish-black with narrow greyish-buff scaling, shading to greyish-brown nape and neck side with pale grey, less contrasting scaling; upperparts mouse-grey, dark brown upperwing and tail; face (lores, cheek, submoustachial area and ear-coverts) blackish-brown; pale ashy brown below, narrow whitish scaling from chin to breast, with flanks and vent warmer brown; iris orange-yellow; bill black; legs brownish-slate. Female is as male, but iris has bright yellow inner ring. Juvenile is paler and tawnier than adult, unscaled, with a white, streaked throat and dark iris. Race *caroliniae* has white over forehead, face and throat; *jubaensis* is paler olive-grey above, ear-coverts not dark greyish, showing white only on mid-throat. Voice. Chorus song "poo-poo-poo-poo...", reportedly one of the most grating and toneless sounds made by any passerine. Groups maintain continuous rasping noise that has peculiar undulating quality. Calls include harsh "chak", "chik" and "chuduk" notes, more explosive "spik" notes, also a repeated "chwik" and throaty "wuk-a-ha, wuk-a-ha..." or "ti-yor ti-yor ti-yor...".

**Habitat.** Dense coastal bush, woodland and undergrowth, thickets along rivers, scrub, to 500 m in Kenya.  
**Food and Feeding.** No information on diet; presumably mainly invertebrates, berries and seeds. Occurs in skulking groups of up to five individuals.  
**Breeding.** Apr in Kenya; nest-building in Oct in Somalia; Jul–Aug in Ethiopia. Eggs pale blue. No other information.  
**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common within often circumscribed habitat along rivers in Somalia; race *caroliniae* at risk from habitat deterioration. Locally common in Kenya.

**Bibliography.** Ash (1981), Ash & Miskell (1983, 1990), Britton (1980), Brown & Britton (1980), Clancey (1984), David & Gosselin (2002b), Fry *et al.* (2000), Jackson & Slater (1938), Lewis & Pomeroy (1989), Stevenson & Fanshawe (2002), Urban & Brown (1971), Wood (1989), Zimmerman *et al.* (1996).

## 183. Northern White-rumped Babbler

### *Turdoides leucopygia*

**French:** Cratérope à croupion blanc **German:** Weißbürdzrossling **Spanish:** Turdoide Culiblanco

**Other common names:** Abyssinian/White-rumped Babbler

**Taxonomy.** *Ixos leucopygius* Rüppell, 1837, central forest region along the coast of north Ethiopia. May form a superspecies with *T. hartlaubii*, perhaps including also *T. melanops* and *T. sharpei*; often treated as conspecific with first-named. Proposed race *clarkei* (from R Baro region of extreme SW Ethiopia) merged with *omoensis*. Five subspecies recognized.

#### Subspecies and Distribution.

*T. l. leucopygia* (Rüppell, 1837) – C Eritrea and adjacent N Ethiopia.

*T. l. limbata* (Rüppell, 1845) – SW Eritrea and immediately adjacent E Sudan S to C Ethiopia.

*T. l. smithii* (Sharpe, 1895) – EC Ethiopia R to NW Somalia.

*T. l. lacuum* (Neumann, 1903) – SC Ethiopia.

*T. l. omoensis* (Neumann, 1903) – SE Sudan and adjacent SW Ethiopia.

**Descriptive notes.** 25–27 cm; 63–93 g. Medium-sized cold grey-brown *Turdoides* babbler with scaly breast, white lower belly and white rump; plumage rather variable. Nominative race has crown greyish-white, well demarcated from grey-tinged cold brown upperparts, white rump, dark brown upperwing and darker brown tail; supercilium buff-tinged white, face (lores, cheek, submoustachial area and ear-coverts) dirty white; chin whitish, throat and neck side to mid-belly cold grey-brown with darker sub-terminal and very narrow whitish-grey terminal scaling, shading on rest of underparts to white; iris red with yellow inner ring; bill black; legs slaty grey. Sexes similar. Juvenile is duller than adult, with brownish crown rather paler than mantle, whitish face and chin. Race *limbata* has blackish-grey crown with silvery-grey scaling, forehead white, face and chin white; *smithii* has whole crown scaled dark grey and silvery, face dirty silvery grey, chin dusky and broader whitish scaling there and to upper belly; *lacuum* is like previous, but with dusky-grey lores, cheeks, submoustachial region and throat, buffier lower flanks and rump; *omoensis* is like last, but lores, cheeks and submoustachial area plainer blackish-grey, throat less grey, more like breast. Voice. Very noisy. Chorus song of harsh chattering calls given. Calls also harsh and scolding.

**Habitat.** Open stony terrain in hilly areas with light woodland, thick scrub on juniper-clad hills, scrub and dense second growth bordering evergreen forest, trees along rivers, scattered thickets, reedbeds, and farmlands; generally at 1250–2450 m, but much lower in Eritrea (not to coastal plains).  
**Food and Feeding.** No information on diet; presumably mainly invertebrates, berries and seeds. Found in family parties or small flocks of 6–8 individuals, keeping inside cover in bottom of vegetation, but foraging largely on ground.

**Breeding.** Nov–Dec and Feb–Jun in Ethiopia and Aug in Somalia. Nest a large untidy cup made of coarse rootlets, coarse grass, twigs and leaves, lined with fibres, placed 1 m or more up in fork of tree or in middle of thick bush. Clutch 2–4 eggs, rich turquoise-blue. No other information.  
**Movements.** Resident.

**Status and Conservation.** Not globally threatened. In Sudan, uncommon and local in E near Eritrean border, but fairly common in SE. Frequent to common throughout Ethiopian Highlands.

**Bibliography.** Archer & Godman (1961), Ash & Miskell (1983, 1998), Benson (1946), Britton (1980), Cave & Macdonald (1955), Cheesman & Slater (1935), Clancey (1984), David & Gosselin (2002b), Friedmann (1937), Fry *et al.* (2000), Neumann (1906), Nikolaus (1987), Safford *et al.* (1993), Schouteden (1956), Urban & Brown (1971).

## 184. Southern White-rumped Babbler

### *Turdoides hartlaubii*

**French:** Cratérope de Hartlaub **German:** Hartlaubdrossling **Spanish:** Turdoide de Hartlaub  
**Other common names:** Angola/Hartlaub's/White-rumped Babbler

**Taxonomy.** *Crateropus Hartlaubii* Bocage, 1868, Bibala, Namibe, Angola.

May form a superspecies with *T. leucopygia*, perhaps including also *T. melanops* and *T. sharpei*; often treated as conspecific with first-named. Proposed race *ater* (from Rwanda S to NE Zambia and SW Tanzania) considered a synonym of nominate. Two subspecies recognized.

#### Subspecies and Distribution.

*T. h. hartlaubii* (Bocage, 1868) – Rwanda and E & SE DR Congo S to NE & W Zambia and SW Tanzania, and to C & SE Angola and NE Namibia.

*T. h. griseosquamata* Clancey, 1974 – WC Zambia S to N Botswana and extreme W Zimbabwe.

**Descriptive notes.** 23–24 cm; 70–92 g. Medium-sized brownish-grey *Turdoides* babbler with pale scaling on head to mantle and throat, white rump, and short stout bill. Nominative race has crown and neck dark brown with greenish-white scaling, frostier white on blacker, blade-centred feathers of forehead, mantle to back dark brown with a few vague pale brown scales, lower rump whitish, upperwing and tail dark brown, lores blackish, supercilium area as crown but with fringes whiter, ear-coverts dark grey-brown with some buff flecking, cheek dark brown with pale greyish fringes; chin to breast mid-brown with vague dark shaft streaking, narrow white fringes, belly mid-brown with buffy-white edges (forming vague long

streaks), thighs and vent buffy grey; underwing and axillaries cinnamon-buff; iris orange-red to crimson, often yellow inner ring; bill black; legs brownish-grey to dark brown. Sexes similar, female may be less brown on throat. Juvenile is much paler on throat and breast, paler generally and less boldly marked than adult, with dark iris. Race *griseosquamata* is paler and more olive-brown above than nominate, with paler and greyer feather fringes, paler below, with finer streaking on flanks, whiter belly and undertail-coverts. Voice. Very noisy. Chorus song a raucous high-pitched babbling "kwekwekwekwekwekwek...", "cheeka-cheeka-cheeka-cheeka..." or petulant nasal "papapapapapapapapapap...", very similar to that of *T. melanops* but slightly higher-pitched, more pinched and nasal. Various harsh, shrill, nasal and often petulant-sounding calls, including "chaaa", "chi-waaaya", "cheeya", "jik" and "jeeyeeyee".

**Habitat.** Patches of dense scrub between woodland and drainage lines, fringes of *Acacia polyacantha* gallery woodland, riverine-forest edge, thickets on termitaria, gardens, marshy valleys with clumps of bushes and tall grass, sometimes reedbeds and papyrus swamps; to 1650 m in DRCongo, and occurring at 1550–2150 m in Tanzania.

**Food and Feeding.** Mainly invertebrates. Frequents middle and lower strata of vegetation, foraging mainly on ground in open. Found in pairs and in parties of 5–15 individuals (average 8), sometimes up to 20 together; often in mixed flocks with *T. jerdoni*.

**Breeding.** Jul–Oct in Angola; bird in breeding condition in Feb in DRCongo; Mar in Tanzania, Apr–May and Oct–Feb in Zambia, and Apr, Aug, Oct and Dec in Botswana; Oct–May (peak Feb) in Zimbabwe. Breeds co-operatively within permanent territory. Nest an untidy bowl of coarse grasses, dry leaves and thin roots, with neat cup lined with fine roots and slender twigs, placed up to 3 m above ground in bush, low tree, tangle of flood debris, or among dense tufts of reeds and sedges. Clutch 2–4 eggs, deep greenish-blue to plain greyish-turquoise; no information on incubation period; nestlings fed by up to four adults, nestling period 18 days in one case. Brood parasitism by Levallant's Cuckoo (*Clamator levallanti*) occurs.

**Movements.** Resident; in Botswana may extend S during rains.

**Status and Conservation.** Not globally threatened. Common in extreme SW Rwanda; abundant on Ruzizi Plain and along shores of L Tanganyika, in Burundi. Locally common in SW Tanzania; widespread in Zambia. Common in Angola. Common to very common in Okavango Basin and various NW river valleys in Botswana; common in Caprivi Strip, in Namibia.

**Bibliography.** Benson & Pitman (1956), Benson & White (1957), Benson *et al.* (1971), Chapin (1953), Clancey (1968, 1974, 1982, 1984, 1985), David & Gosselin (2002b), Dean (2000), Fry *et al.* (2000), Ginn *et al.* (1989), Harrison *et al.* (1997), Hustler (1997), Irwin (1981), Moyer (1983), Newman (1989), Payne & Payne (1967), Penny (1994), Skinner (1995), Stevenson & Fanshawe (2002), Traylor (1965), White & Winterbottom (1949), Winterbottom (1939), Wyndham (1948).

## 185. Hinde's Pied Babbler

### *Turdoides hindei*

**French:** Cratéope de Hinde **German:** Hindedrossling **Spanish:** Turdoide de Hinde  
**Other common names:** Hinde's Babbler

**Taxonomy.** *Crateropus hindei* Sharpe, 1900, Athi River, Kenya.

Has been thought possibly to be part of a superspecies with *T. sharpei*, *T. squamulata* and *T. hypoleuca*. Monotypic.

**Distribution.** SC Kenya.

**Descriptive notes.** 20–23 cm; 58–77 g. Smallish piebald *Turdoides* babbler, dark brown with extensive white scaling, buff flanks and white belly; no two individuals quite alike, owing to much partial albinism in which white tips can occur (asymmetrically) on wings and tail, and rufous markings may appear anywhere on head and body. Typically, has sooty-brown head, breast, mantle and lesser upwing-coverts thickly covered with variable-width white scales, rump rufous or same as back but heavily tinged rufous, upperwing rufescent dark brown, tail dark brown, belly creamy white, thighs dark grey-brown, flanks and vent buffy

rufous to rufous; iris red; bill black; legs horn. Sexes similar. Juvenile has browner, less bronzy wings and tail, greyish iris. Voice. Chorus song a noisy chattering "rukakakakakaka...", like that of *T. hypoleuca* but faster, individual birds calling "ruka" before and after; variation is a grating "ta-jaaa", growing in chorus to protracted screeching "d'jaaaaaay". Calls include repeated loud downslurred bray, "dayoo" (similar to that of *T. squamulata*), rambling "chare-chare-chare", chattering "chirr-chirr...", "cherak-chwak-chakchakchakchak", with a hiccup-like alarm.

**Habitat.** Thickets and secondary growth with some remaining trees in river valleys, particularly in fallow and abandoned areas where alien *Lantana camara* established, fringes of cultivation with scattered trees and bushy cover, also along bushy streams and gulleys in drier open woodland; feeds in coffee and maize plantations, but territories confined to areas with dense vegetation associated with permanent or seasonal water. Significantly more groups present in areas with more than 3% thicket cover (and breeding success improves with more than 9% cover), but group density levels out at 15–20% cover. Original habitat judged to have been rocky hillsides and valleys with *Combretum*, *Terminalia*, *Croton*, *Cussonia*, *Cassia* and *Commiphora*. At 1070–1700 m.

**Food and Feeding.** No information on diet; presumably mainly invertebrates, berries and seeds. Nestlings observed fed on "dark glutinous mass" brought from under bushes. Found in small flocks of 4–8 individuals throughout year; forages at least part of time on open ground, with sentries.

**Breeding.** Feb, Apr and Aug–Oct. Solitary, co-operative breeder; mean group-territory size 3.75 ha. Nest an open cup made of coarse grass, lined with finer grass. Clutch 2–3 eggs, pale blue; no information on incubation and nestling periods. Brood parasitism by Jacobin Cuckoo (*Clamator jacobinus*) reported. In one study, only one of five nesting attempts was successful, the others failing owing to predation or human disturbance.

**Movements.** Resident.

**Status and Conservation.** VULNERABLE. Restricted-range species; present in Kenyan Mountains EBA. Scarce and very local. Substantial contraction of range in response to agricultural expansion, reported in 1979, appears not to have occurred, although in 2000 a loss of more than 20% of its range was expected. Current range size estimated at 18,800 km<sup>2</sup>, and population judged to be between 2500 and 10,000 mature individuals; this latter estimate based on average density of 2.4 birds/km<sup>2</sup>. Survey of six sites in 2000–2001 produced minimum population figure of 665 birds in 157 groups, with 75% in two intensively farmed sites and 97% in or adjacent to five Important Bird Areas; extrapolation suggested that global population was then 1500–5600 individuals. Clearance and fragmentation of habitat owing to expanding and intensifying farming are major threats; rice irrigation

and dams along R Tana may also have destroyed thickets, while disturbance appears to cause low breeding success and hunting for food causes direct losses in some areas. Three protected areas harbour populations: Mwaa National Reserve, Meru National Park and the small, privately owned Wajee Camp (near Mukurweini), but only c. 8% of total population in these reserves. Restoration of habitat so that thicket cover reaches 10% likely to result in greater productivity in population.

**Bibliography.** Anon. (2006d), Blencowe (1961), Britton (1980), Buichart & Stattersfield (2004), Collar & Stuart (1985), Friedmann (1937), Fry *et al.* (2000), Jackson & Sclater (1938), Kamiti (2003), Lewis (1984), Lewis & Pomeroy (1989), Njoroge & Bennun (1999), Njoroge & Mutinda (1996), Njoroge *et al.* (1998), Plumb (1979), Shaw (1996), Shaw & Musina (2003), Shaw *et al.* (2003), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stevenson & Fanshawe (2002), Turner (1992), Zimmerman *et al.* (1996).

## 186. Northern Pied Babbler

### *Turdoides hypoleuca*

**French:** Cratéope bigarré **German:** Bronzedrossling **Spanish:** Turdoide Pío

**Taxonomy.** *Crateropus hypoleucus* Cabanis, 1878, Kitui, Kenya.

Has been thought to form a superspecies with *T. sharpei* and *T. squamulata*, possibly including also *T. hindei*. Two subspecies recognized.

**Subspecies and Distribution.**

*T. h. hypoleuca* (Cabanis, 1878) – C & S Kenya S to N Tanzania (Mt Kilimanjaro).

*T. h. rufuensis* (Neumann, 1906) – NE Tanzania.

**Descriptive notes.** 22–25 cm; 67–80 g. Medium-sized *Turdoides* babbler, brown above and white below, with partial or full breastband. Nominata race has crown, nape and mantle plain brown with faint, pale greyish-brown scaling, remaining upperparts, upperwing and tail plain brown, whitish spots on median and lesser wing-coverts; face (lores, superciliary area, cheek and ear-coverts) plain dark brown, neck side, flanks, thighs and partial or complete breastband the same but with faint, pale greyish-brown scaling, remaining underparts (including submoustachial area) white, sometimes with buffy tinge (one individual recorded

with entire underside except throat dingy grey brown); iris creamy white, sometimes pale yellow or straw; bill black; legs dusky. Sexes similar. Juvenile is slightly more olivaceous than adult, streaked on breast, iris dark. Race *rufuensis* is paler and greyer above, with scaling extending onto back, crown more extensively and densely flecked and scaled buffy grey, often also with greyer head side, darker lores, more extensive breastband. Voice. Very noisy. Chorus song a loud "teeya-teeya-teeya", "skare-skare-skare-skare..." or longer "teeyayayayaya", lacking churring quality of F African congeners. Calls include nasal, complaining, slightly downslurred and fading "taaaa" or "yaaaa", insistent "quorr-quorr", and variety of raucous chattering, churring and chuckling notes.

**Habitat.** Middle-elevation bushlands, edges of dry evergreen forest, secondary growth, patches of *Erythrina* and nearby clumps of bushes and trees, scrub, plantations, suburban gardens, areas near human habitation; in Kenya study, groups spend midday in *Lantana* thickets. Generally at 1000–1800 m.

**Food and Feeding.** No information on diet; presumably mainly invertebrates, berries and seeds. Forages mostly on ground under thick cover of bushes, tossing and turning dead leaves and debris in search of prey; in evening, feeds close to roost-site. Found in family parties of 3–5 individuals and larger groups of up to 10–12 (average 8.3) individuals; in small groups during breeding season.

**Breeding.** Feb–Dec (peaks Apr–May and Nov) in Kenya and Nov and Feb in Tanzania. Nest a rough cup of leaves, twigs and coarse dry grasses (one incorporated *Bougainvillea* flowers and dog hair), lined with finer grasses, rootlets and fibres, usually placed 1.5–3.7 m up in thorny bush. Clutch 3–4 eggs, usually 3, rich dark blue, sometimes with faint brown spotting. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Range relatively small. Locally common in Kenya, and a common bird in Nairobi gardens. In Tanzania occurs in three populations: one (around Mt Kilimanjaro) with 50 recorded localities; another (Kilosa) where fairly common, with 23 localities; and third from Usambaras towards Tanga (abundance/localities unreported).

**Bibliography.** Britton (1969, 1980), Brown & Britton (1980), David & Gosselin (2002b), Friedmann (1937), Fry *et al.* (2000), Jackson & Sclater (1938), Lewis & Pomeroy (1989), Njoroge & Mutinda (1996), Njoroge *et al.* (1998), Plumb (1979), Shaw & Musina (2003), van Someren (1939), Stevenson & Fanshawe (2002), Zimmerman *et al.* (1996).

## 187. Southern Pied Babbler

### *Turdoides bicolor*

**French:** Cratéope bicolore **German:** Elsterdrossling **Spanish:** Turdoide Bicolor  
**Other common names:** Bicoloured/Pied Babbler

**Taxonomy.** *Cratopus bicolor* Jardine, 1831, South Africa.

Monotypic.

**Distribution.** N & NE Namibia, Botswana, SW & S Zimbabwe, N & NE South Africa and SW Mozambique.

**Descriptive notes.** 24–25 cm; 63–96 g. Medium-sized white *Turdoides* babbler with black bill, wings and tail. Head and body are pure white, with brownish-black tail and wing, latter with white innermost greater coverts and median and lesser coverts; iris reddish-orange to orange-yellow or golden; bill black; legs black to brown. Sexes similar. Juvenile is olive-brownish, with dark shaft streaks on forehead, ear-coverts ashy brown, paler on lower belly, dark brown wings and blackish tail; starting at 3–4 weeks post-fledging, white feathers acquired gradually over 4–6 months (birds of this age having irregular blotches of brown and

white, looking piebald). Voice. Chorus song involves various harsh but quite high-pitched chattering notes, "cha-cha-cha", "keey-keey-keey", "kawa-kawa-kawa", "kwee kwee kwee kwee" etc.

one bird begins "sk-sk-sk-sk-skerr-skerr-skerra-skerra" or "jajajajijijijeeeyi-jeeeyi-jeeeyi-jeeeyi" and other party-members join in, notes becoming double at height of calling, slowing to "kawäck-kawäck-kawäck...". Calls include various crowing notes; challenge note like that of Green Woodhoopoe (*Phoeniculus purpureus*); adult uses "purr" call to summon independent fledglings to patch of abundant food.

**Habitat.** Semi-arid to arid savanna (avoiding more open areas and more mesic woodlands), often with abundance of corkwood (*Commiphora*) and acacia and sparse covering of grass; also thornveld, dry broadleaf woodland, acacias and bushy undergrowth bordering rivers; low blackthorn (*Acacia mellifera*) woodland in W Botswana, and in taller camelthorn (*Acacia erioloba*) woodland and exotic mesquite (*Prosopis*) in Kalahari. Ranges up to 1200 m in Zimbabwe.

**Food and Feeding.** Insects, including tenebrionid beetles, beetle larvae, caterpillars and moths (Lepidoptera), grasshoppers (Orthoptera), ants (Formicidae), termites (Isoptera), large ticks (Ixodes), sun-spiders (Solifugae), scorpions, small reptiles (burrowing skinks, lizards, grass snakes) and amphibians (frogs); group disturbed from a kudu (*Tragelaphus strepsiceros*) carcass were probably taking maggots. Forages mainly on ground, tossing leaves aside in search of food, digging in soil, searching bases of grass clumps, picking through dung, breaking open termite tunnels, creeping through tangled undergrowth, climbing among thorny twigs and vines; bill often used as dagger to stab prey. Found in groups of up to 15, usually consisting of 6–10 adults and up to three immatures. Frequently forages in company with other bird species, and in particular reported to form associations with Red-billed Buffalo-weaver (*Bubalornis niger*) and Crimson-breasted Shrike (*Laniarius atrococcineus*); at least in Kalahari, also has common association with Fork-tailed Drongo (*Dicrurus adsimilis*). In parts of range close ecological overlap with *T. jardineii* occurs, resulting sometimes in co-existence, sometimes in competition.

**Breeding.** Oct–Apr in Namibia, Sept–May (mainly Oct–Dec) in Botswana and Aug–Jan (mainly Nov) in Zimbabwe; Oct–Jan and Mar in N South Africa; up to five attempts per group per year reported, with at least one young fledged per attempt, intervals between successive clutches 2–12 weeks (rainfall-dependent). Co-operative breeder, with up to twelve helpers at nest; territories in acacia savanna 35–50 ha, but territorial groups may place nests in neighbouring trees. Nest, built by dominant male and female in group, occasionally with help of third bird, over period of up to 26 days, a large, rough, fairly deep open bowl made of long dry stems and thin twigs, neatly lined with hair and fine soft fibres, fine rootlets, fine grasses and similar, placed 1.5–3 m above ground in outer branches or multiple internal fork of thorny bush or tree (typically, *Acacia* or *Ziziphus*); old nest of Wattled Starling (*Creatophora cinerea*) also used; new nest constructed for each breeding attempt (one record of re-use of original nest). Clutch 2–5 eggs, usually 3, very pale bluish-green to whitish; incubation and nestling periods both c. 16 days in one case; young provisioned by all group-members for up to 14 weeks after fledging, but post-fledging dependence sometimes as short as 40 days. Infrequent brood parasitism by Levillant's Cuckoo (*Clamator levaillantii*) occurs.

**Movements.** Resident, but groups may wander in response to local conditions; considered vagrant in Free State, in South Africa.

**Status and Conservation.** Not globally threatened. Locally common. Widespread in N Namibia; common to very common throughout most of Botswana. Widespread in Hwange National Park, in Zimbabwe, but localized elsewhere in country. Locally common in Northern Cape and fairly common in Limpopo Province, in South Africa. Density in acacia savanna 8 birds/km<sup>2</sup>.

**Bibliography.** Allan (2002), Barbour (1972), Clancey (1971), Dowsett & Dowsett-Lemaire (1993), Fry *et al.* (2000), Ginn *et al.* (1989), Harrison *et al.* (1997), Hockey *et al.* (2005), Hoesch (1934), Irwin (1981), Lindeque & Kapner (1993), Newman (1989), Peacock (2006), Penry (1994), Radford & Ridley (2006), Ridley (2006), Ridley & Rathani (2007), Skinner (1995), Tyler (2002a, 2002b).

## 188. Bare-cheeked Babbler

### *Turdoides gymnogenys*

**French:** Cratérope à joues nues **German:** Nacktwangendrossling **Spanish:** Turdoide Caricalvo

**Taxonomy.** *Crateropus gymnogenys* Hartlaub, 1865, Benguela Province, Angola. Two subspecies recognized.

**Subspecies and Distribution.**

*T. g. gymnogenys* (Hartlaub, 1865) – SW Angola.

*T. g. kaokensis* (Roberts, 1937) – NW Namibia.

**Descriptive notes.** 24–25 cm; 65–91 g. Medium-sized *Turdoides* babbler, mid-brown above and white below, with pale greyish crown, black skin on face and buffy-rufous nape and neck sides. Nominative race has crown pale greyish with white and buffy tinges and some small black shaft streaks, shading to pale-scaled buffy rufous on nape and neck sides and to buffy-scaled mid-brown on mantle, plumage slightly darkening posteriorly but with white rump, and dark brown upperwing and tail; lores and supercilium white, bare black skin from bill below eye to ear-coverts (often crossed by strips of white feathers, so appearance as much "bar-cheeked" as "bare-cheeked"); lower face and underparts white, some buffy rufous on flanks (probably not usually visible in field); iris lemon-yellow (sometimes grey-brown in male, whitish or pale yellow in female); bill black; legs dusky grey to brownish-flesh. Sexes similar. Juvenile has slightly stronger greyish-brown crown and less intense buffy-rufous nape and neck sides than adult. Race *kaokensis* is like nominate, but mantle and scapulars slightly paler brown, buffy rufous of neck side, breast side and flanks also paler, smaller bare patch on ear-coverts more broken by thin lines of white feathers. **Voice.** Chorus song a loud chattering "kerrakerrra-kek-kek-kek", very like that of *T. jardineii*, which arises out of continuous low grating "chuk... chuk... chuk..." contact call, also described as a harsh "jeeee-jeeee-jeeee..." or "jaaa-jaaa-jaaa...". Sentinel birds give soft "lull lull lull" call.

**Habitat.** Undergrowth of dry broadleaf riverine woodland, woodland on open plains, thick thorny brush on bare rocky ground, tamarisk and other thickets along seasonal watercourses, rocky semi-wooded hills and slopes. In Namibian study, density highest in riverine habitats.

**Food and Feeding.** Mainly insects and their larvae, including beetles (Coleoptera), caterpillars (mopane worms), termites (Isoptera) and mantids; also some vegetable matter. Forages in pairs or in family groups of 2–11 individuals (mean 6), mainly on ground and in low vegetation, often thereby attracting other species and becoming nucleus of mixed flock, including congeners and such species as shrikes (Laniidae). Turns over leaf litter and probes bases of grass clumps.

**Breeding.** Mainly Nov–Jan (Jul–Jan, also Apr–May) in Namibia. Co-operative breeder; up to twelve birds attending one nest. Nest a loose bulky bowl made of dry grass and herb stems, lined with finer grasses, placed c. 2 m up in multiple fork in tree (e.g. *Terminalia* or *Spirostachys*). Clutch 2–3 eggs, glossy turquoise-green; no information on incubation period; nestling period at least 16 days. Brood parasitism by Levillant's Cuckoo (*Clamator levaillantii*) occurs. Breeding success higher in well-wooded habitat: 0–39 fledged young per adult in densest riverine stands, 0–27 in less dense areas, and 0–16 in least dense areas, success not related to group size.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Uncommon in Angola. Uncommon to locally common in Namibia, where range covers 85,000 km<sup>2</sup> and population estimated at 53,170–104,970 individuals; density along watercourses c. 3–6 birds/km, mean distance between neighbouring groups 1–7 km and overall density 0–6 groups/km<sup>2</sup>; present in Etosha National Park. Abundance in any given year related to rainfall, at least in riverine habitats.

**Bibliography.** Clancey (1985, 1989), Dean (2000), Fry *et al.* (2000), Ginn *et al.* (1989), Hall & Moreau (1970), Harrison *et al.* (1997), Hockey *et al.* (2005), Jarvis & Robertson (1999), Robertson *et al.* (1995), Shaw (2001a), Shaw & Shewry (2000), Traylor (1963), Vernon (1982).

## PLATE 14

## Family TIMALIIDAE (BABBLERS) SPECIES ACCOUNTS

### Genus *PHYLLANTHUS* Lesson, 1844

#### 189. Capuchin Babbler

##### *Phyllanthus atripennis*

**French:** Phyllanthe capucin **German:** Schwarzflügelimalie **Spanish:** Charlatán Capuchino

**Taxonomy.** *Crateropus atripennis* Swainson, 1837, Senegal.

Race *rubiginosus* is reported to intergrade with *bohndorffi* eastwards from Nigeria towards Central African Republic, in zone where precise distribution is unclear and very local. Central populations formerly known as *haynesi* but this name is a junior synonym of *rubiginosus*. Three subspecies currently recognized.

##### **Subspecies and Distribution.**

*P. a. atripennis* (Swainson, 1837) – Gambia and Senegal S to Liberia.

*P. a. rubiginosus* (Blyth, 1865) – S Ivory Coast E to C & S Nigeria and W Cameroon.

*P. a. bohndorffi* (Sharpe, 1884) – S Central African Republic and NE DR Congo E to SW Uganda.

**Descriptive notes.** 21–24 cm; 75–96 g. Stout, chunky, short-tailed babbler, blackish-maroon with creamy-yellowish bill, grey head and distinctive hoarse calls. Nominative race has crown slaty black centrally with narrow grey edges, shading to grey on superciliary area and nape, grey continuing to neck side, ear-coverts, cheek and chin to upper breast; area around eye with brighter silvery flecks, and area from neck side to breast with vague darker scaling or mottling; adjacent areas (mantle, lower neck side, breast) blackish, shading irregularly to rich maroon on remaining body plumage; upperwing dark brown, tail blackish-brown; iris brown to dark

red-brown; bill creamy to pale yellowish-green; legs olive-green to grey. Sexes similar. Juvenile has dark brown iris. Race *rubiginosus* is brighter reddish-chestnut than nominate, with crown entirely blackish, no blackish on mantle to breast, grey of throat not extending onto breast; *bohndorffi* is like previous but somewhat smaller, with forehead black, whole rest of crown to submoustachial area sealy grey, and chin and throat entirely maroon. Voice. Chorus song an excited raucous cackling mixed with grating trills, “krrrrrr...” or “kekekeke...”, accelerating into piercing squeaks when flock disturbed. A surprisingly musical whistle, pure and downslurred, “whooh whooh” or “hiiiu” or “fweeu”, between normal chattering notes may also be song. Contact calls are little hoarse grunts, “kerk”, “kawk”, “ufufuf” or “augh”, conversational “weeu weeu” and single soft “quack”, in alarm, becomes very noisy, giving harsh notes with variations described as “kaaa”, “kk kk kk” (“cht”), “kaa kaa kaa kaw” and “kiorr-kiorr” or “chrrrrr”.

**Habitat.** Shady undergrowth, thick leafy tangles, dense thickets and lush streamside growth in broadleaf evergreen forest, primary mountain forest, dense secondary forest and secondary growth, forest edge (sometimes bordering cultivation), forest remnants in savanna, wooded gulleys, occasionally savanna woodland; sometimes well-wooded gardens. Keeps to darkest, thickest parts of cover, and very retiring. Lowlands; in Uganda, at 700–900 m in Bwamba but with record at 1700 m in Bwindi.

**Food and Feeding.** Mainly invertebrates, including ants (Formicidae), small beetles (Coleoptera), cockroaches (Mantodea), grasshoppers (Orthoptera), caterpillars, pupae and larvae, millipedes (Diplopoda) and small snails; also small amphibians, and seeds. Forages in lower and middle sto-

reys, to 3–4 m, and on ground. Follows driver ants (*Dorylus*), and seen to follow group of foraging long-nosed cusimanses (*Crassarchus obscurus*) for several hours. Found in noisy groups of 4–12 (usually 5–7) individuals, sometimes in pairs; associates with other species, including *Turdoides reinwardtii*, in mixed foraging flocks.

**Breeding.** Nest-building in Jun and food-carrying in Nov in Gambia; birds in breeding condition in Mar and Jun–Aug in Liberia; Nov–Feb in Sierra Leone; Jan–Feb and Jun–Oct (probably all year) in DR Congo; breeding-condition bird in Oct in Uganda. Nest a large, untidy cup of green moss and dead leaves, lined with pliable hard rootlets, placed 3–4.5 m up in sapling, bush or creeper-laden oil palm (*Elaeis*). Clutch 2 eggs, pale blue. No information on incubation and nestling periods. Brood parasitism by Levallant’s Cuckoo (*Clamator levallantii*) inferred from presence of fledgling cuckoo in group.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally uncommon to fairly common but local across range. Rare but evidently resident in Gambia; fairly common in Senegal in SW; frequent in coastal Guinea-Bissau; frequent on Freetown Peninsula, in Sierra Leone; fairly common near coast and in highlands in N Liberia; frequent at Mt Nimba, in Taï Forest National Park and along N gallery forest but otherwise scarce in Ivory Coast; fairly common and widespread in S Ghana; rare in Benin. In Nigeria, frequent in SW but rare and local from there E to Central African Republic, with only two records in Cameroon before 1980. Widespread in Uele, Aruwimi and Ituri districts of DR Congo; fairly common in Bwamba lowlands and recorded from Bwindi-Impenetrable Forest National Park, in Uganda. Earlier reports of this species from Mali, including movement N in rains, now considered erroneous. Easily netted and snared; groups can often be taken for food by local people.

**Bibliography.** Bannerman (1951, 1953), Barlow *et al.* (1997), Borrow & Demey (2001), Britton (1980), Carswell *et al.* (2005), Chapin (1953), Cheke & Walsh (1996), Claffey (1995), Colston & Curry-Lindahl (1986), Dowsett-Lemaire & Dowsett (2005), Elgood *et al.* (1994), Field (1974), Fry *et al.* (2000), Gatter (1997), Gore (1990), Grimes (1987), Hall & Moreau (1970), Hayman *et al.* (1995), Louette (1981), Morel & Morel (1990), Stevenson & Fanshawe (2002), Wacher (1993).

### Genus *KUPEORNIS* Serle, 1949

#### 190. White-throated Mountain Babbler

##### *Kupeornis gilberti*

**French:** Phyllanthe à gorge blanche **German:** Weißkehltimalie **Spanish:** Charlatán Goliblanco

**Taxonomy.** *Kupeornis gilberti* Serle, 1949, Kupé Mountain, Cameroon.

Genus has been merged with *Liottilus*, but perhaps closer to *Phyllanthus*; differs from latter in smaller and weaker bill with relatively broader base (less laterally compressed); more slit-like nostrils (as *Turdoides*), and more slender feet. Monotypic.

**Distribution.** SE Nigeria (Obodu Plateau) and SW Cameroon.

**Descriptive notes.** 21–23 cm; 64 g. Large brown-and-white forest babbler with olivaceous brown body and white face and breast. Crown is dull chestnut, clear-cutting on nape to bronzy olive-brown upperparts and upperwing, becoming rufescent on rump and chestnut on uppertail-coverts; tail very dark olive-brown with rufescent outer fringes; face (lores, supercilium, cheek, ear-coverts and submoustachial area) white with pale vinous-chestnut tinge, chin to mid-breast pure white, remaining underparts olive-tinged dull chestnut-brown, undertail-coverts richer, iris greyish-white to pale bluish-grey; bill pale brown, dirty white lower mandible; legs greenish-grey or bluish-grey.

Sexes similar. Juvenile has entire ear-coverts, cheeks, chin and throat brown, with only 2–3 white feathers; immature male has white throat and ear-coverts with sparse brown spotting, more rufous underparts. VOICE. Call a harsh explosive “chak”, “chook” or “chrook”, usually given singly but occasionally up to four times in rapid succession; also soft “kion”. Flocks often make harsh concerted chatter.

**Habitat.** Primary montane forest with high rainfall apparently crucial, but seen in mature secondary growth, including scrubby but mossy *Maesa lanceolata* forest 10 m tall, and also in conifer trees around cattle-ranch build-

ings on Obudu Plateau; found at 950–2135 m, but distribution (particularly altitude) seems well correlated with that of thick epiphytic moss.

**Food and Feeding.** Mainly insectivorous. Travels through forest in highly active, excitable and vocal flocks of up to twelve individuals, occasionally up to 20. Parties advance slowly through canopy and middle stratum, occasionally descending to undergrowth. Searches for food among moss, epiphytes and crevices in bark, often perching upside-down. Often associates with flocks of Grey-headed Greenbul (*Phyllastrephus poliocephalus*) and other species. Behaviour said to resemble that of *Phyllanthus atripennis*.

**Breeding.** Apr–Jan. Nest a large untidy cup of moss and bits of fern, placed c. 10 m above ground at base of branch against trunk, among strangler figs in large tree. No other information.

**Movements.** Resident.

**Status and Conservation.** ENDANGERED. Restricted-range species: present in Cameroon Mountains EBA. Although the species has recently been found at several new sites, its total range is very small and its montane-forest habitat is threatened and continues to decline in extent and quality at some localities. Estimated range 1990 km<sup>2</sup>, within which locally fairly common to common. Common on Obudu Plateau and, in 1999, found to be very common on Mt Manenguba. The two most important sites, both in Cameroon, are Bakossi Mts and Rumpi Hills, because of the area of suitable forest remaining; in 1998, population in Bakossi estimated at several thousand individuals. Undisturbed forest throughout its range is under pressure from exploitation for timber and firewood, intensive grazing, fire and clearance for agriculture. There is an ongoing conservation and development project at Mt Kupé, but the forest still has no legal protection and there has been a slow extension of farmland on N slopes. Forests of Bakossi are still waiting to be classified, probably partly as forest reserves (open to timber concessions) and partly as protected areas. The Banyang Mbo Wildlife Sanctuary is the focus of a major conservation programme. A small area of montane forest is protected on the Obudu Plateau.

**Bibliography.** Anon. ## 191. Red-collared Mountain Babbler

### *Kupeornis rufocinctus*

**French:** Phyllanthie à collier roux **German:** Rostbandtimalie **Spanish:** Charlatán Cuellirrojo  
**Other common names:** Red-collared Babbler/Blackcap

**Taxonomy.** *Lioptilus rufocinctus* Rothschild, 1908, Ruge Forest, south-western Rwanda. Genus has been merged with *Lioptilus*, but perhaps closer to *Phyllanthus*; differs from latter in smaller and weaker bill with relatively broader base (less laterally compressed), more slit-like nostrils (as *Turdoides*), and more slender feet. Present species forms a superspecies with *K. chapini*, and sometimes considered conspecific. Monotypic.

**Distribution.** E DR Congo, SW Uganda, Rwanda and N Burundi.

**Descriptive notes.** 19–20 cm. Sociable, noisy, tail-flicking dull olive-brown babbler with dusky cap, wings and tail, rufous neck, breast and rump, and whitish eye. Crown, lores and superciliary area are black, upper submoustachial streak blackish, upper malar area and chin buffy, and nape, neck side and ear-coverts to throat and breast rufous; upperparts and lower underparts olive-brown, except for rufous rump and vent; upperwing and tail blackish-brown; iris yellowish-white or pale straw-yellow; bill whitish-brown, dusky around nostrils; legs pale grey. Sexes similar. Juvenile has dark eye. VOICE. Call harsh and

chattering, often in chorus, similar to that of *Turdoides* although quieter and rather rustling; also written plainly as “chuck”.

**Habitat.** Broadleaf evergreen forest, preferring very moist areas where trees covered in mossy epiphytes, also dense thickets in bamboo forest; at 1500–3200 m.

**Food and Feeding.** Insects; occasionally small fruits. Gregarious, occurring in groups of 3–15 individuals which forage together on trunks and branches of trees, probing aggressively among large masses of epiphytes, often hanging head-down, tail constantly moved up and down. Sometimes in bird waves, most commonly with White-headed Woodhoopoe (*Phoeniculus bollei*).

**Breeding.** Nest-building in Apr–May, copulation seen May–Jul and dependent young Jun–Aug in Rwanda. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Albertine Rift Mountains EBA. In favourable habitat, can occur at high density, each group having home range of 20–25 ha. Known from only a few sites, and the level of threat to these, particularly as a result of clearance for shifting agriculture, means that this species’ long-term future is far from secure.

**Bibliography.** Anon. (2006d), Butchart & Stattersfield (2004), Chapin (1953), Dowsett-Lemaire (1990), Fry *et al.* (2000), Prigogine (1960, 1964), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stevenson & Fanshawe (2002), Vande weghe (1988).

## 192. Chapin’s Mountain Babbler

### *Kupeornis chapini*

**French:** Phyllanthie de Chapin **German:** Chapintimalie **Spanish:** Charlatán de Chapin  
**Other common names:** Chapin’s Babbler

**Taxonomy.** *Kupeornis chapini* Schouteden, 1949, Mongbwalu, north-east DR Congo.

Genus has been merged with *Lioptilus*, but perhaps closer to *Phyllanthus*; differs from latter in smaller and weaker bill with relatively broader base (less laterally compressed), more slit-like nostrils (as *Turdoides*), and more slender feet. Present species forms a superspecies with *K. rufocinctus*, and sometimes considered to be conspecific. Individuals of present species seen in mountains W of L Kivu not assigned to race, but possibly belong with nominate. Three subspecies recognized.

**Subspecies and Distribution.**

*K. c. chapini* Schouteden, 1949 – E DR Congo (from W of L Albert S to W of L Edward).

*K. c. nyombensis* (Prigogine, 1960) – Mt Nyombe region of E DR Congo.

*K. c. kalindei* (Prigogine, 1964) – W of N end of L Tanganyika (E DR Congo).

**Descriptive notes.** 18–19 cm. Broadly similar to *K. rufocinctus*, but with blackish-chestnut cap, paler rufous throat, pale chestnut wing flash. Nominative race has crown dark chestnut, sometimes with blackish scaling, switching abruptly to olive upperparts except for rufous-chestnut rump; dark olive-brown upperwing with rufous-edged primaries (dull wing flash), tail blackish-brown; face (lores, superciliary area, cheek and ear-coverts) pale ochrous-olive; chin and upper submoustachial area buffy, shading on lower submoustachial area, throat and upper breast to dull rufous, which in turn shades on breast side, lower breast and remain-

ing underparts to rufous-tinged dull ochrous-olive, vent dull chestnut; iris dark; bill brownish, paler lower mandible; legs dark brown. Sexes similar. Juvenile has crown more maroon-brown. Race *nyombensis* has duller crown than nominate, grey sides of head, paler throat; *kalindei* is like previous but darker on crown, face and upperparts, with wing flash and vent brighter rufous. VOICE. Call harsh and chattering, often in chorus; similar to that of *K. rufocinctus*, but somewhat higher-pitched.

**Habitat.** Transitional broadleaf evergreen forest, at 1000–1650 m.

**Food and Feeding.** No information on diet. Found in flocks of up to ten individuals, foraging in middle and upper storeys of forest. Associates with other species, particularly bulbuls (Pycnonotidae), in bird waves.

**Breeding.** May–Jun. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Albertine Rift Mountains EBA. Evidently rather rare. Has a relatively small range, and its habitat is under threat as a consequence of clearance for shifting agriculture.

**Bibliography.** Anon. (2006d), Butchart & Stattersfield (2004), Chapin (1953), Fry *et al.* (2000), Lippens & Wille (1976), Prigogine (1960, 1964, 1971), Schouteden (1949, 1956), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Vande weghe (1988).

**Bibliography.** Ali & Ripley (1972), Ali *et al.* (1996), Allen *et al.* (1997), Berlioz (1930), Choudhury (2003), Godwin-Austen (1874), Grinnett *et al.* (1938), Harrington (1909, 1914a), Hume & Oates (1889), Inskip & Inskip (1991), Inskip *et al.* (2000), Kinnear (1994), Ludlow & Kinnear (1997, 1944), Meyer de Schauensee (1984), Rasmussen & Anderton (2005), Ripley (1952, 1961), Ripley *et al.* (1991), Robson (2000), Singh (1995), Smythies (1940, 1949), Spierenburg (2005), Stanford & Mayr (1941), Stanford & Ticehurst (1938), Stevens (1923), Stuart Baker (1933), Wang ZhiJun & Wei Tianhao (1983).

### 196. Chestnut-winged Laughingthrush

*Dryonastes berthemyi*

**Other common names:** Buffy Laughingthrush, Chinese Rusty Laughingthrush

**Distribution.** SE China: NW & C Yunnan and SC Sichuan E to C Guizhou, Hunan, SE Anhui and NW Zhejiang. S to NE Guangxi. N Guangdong and NW Fujian.

to buff and tinges mid-grey; vent white; iris grey or brown with blue outer ring; orbital skin blue; bill black, yellow tip; legs yellowish-tan. Sexes similar. Juvenile is generally duller than adult, crown paler, less obvious white fan tips. **Voice.** Song consists of loud, melodious and variable whistles, including 'hi-hi-hoo-hoo-hoo-hoo-hoo-hoo' ('hi' subdued, weak and rising, 'hoo'

**Bibliography.** Berlitz (1930), Caldwell & Caldwell (1931), Cheng Tsohsin (1976, 1987), Cheng Tsohsin *et al.* (1963), Collar (2006), David & Oustalet (1877), Deng Xuejian *et al.* (1995), Dowell *et al.* (1997), Huang Qing, Deng Heli & Mao Ke (1995), Huang Qing, Huang Yongzhao & Deng Heli (1993), King (1989a), La Touche (1925–1930), Lee Kwok Shing *et al.* (2006), Lewthwaite (1956), Li Guiyuan *et al.* (1993), Liu Kezhi *et al.* (1994), Meyer de Schauensee (1984), Stressemann (1923c), Traylor (1967), Wang Zhijun & Wei Tianhao (1983), Wu Zhikang *et al.* (1986), Zhu Xi & Fan Houde (1995).

### 197. Rusty Laughingthrush

*Dryonastes poecilorhynchus*

**Other common names:** Scaly-headed/Rufous Laughingthrush, Taiwan Rusty Laughingthrush

**Distribution.** Taiwan.

**Bibliography.** Berlioz (1930), Caldwell & Caldwell (1931), Cheng Tsohsin (1987), Collar (2006), Hachisuka & Udagawa (1950, 1951), Isenberg (1970), Koh Chaonien & Lee Peifen (2003), Meyer de Schauensee (1984), Severinghaus & Blackshaw (1976), Smith & Yu Hontsen (1992), Yen Chungwei (1990).

### 198. Black-throated Laughingthrush

*Dryonastes chinensis*

*D. c. propinquus* Salvadori, 1913 - S Myanmar (Tenasserim) and W Thailand.

*D. c. chinensis* (Scopoli, 1786) – SE China (SE Yunnan E to Guangxi and C Guangdong), NE, C & S Laos and Vietnam (S to C Annam).  
*D. c. monachus* (Swinhoe, 1870) – Hainan I.  
*D. c. germaini* Oustalet, 1890 – S Vietnam (S Annam, Cochinchina) and adjacent E Cambodia.

**Descriptive notes.** 23–30 cm; 64–113 g. Dark, medium-sized laughingthrush with black on face and throat. Nominant race has forehead, bristly lores and upper submoustachial area black, black extending as eyestripe around and behind eye, narrow uneven flecks of white above black on forehead; crown and upper nape slate-grey with slight bluish tinge, shading through mid-grey on mantle to olive-tinged dark brown on remaining upperparts, upperwing and tail slightly browner, latter blackish distally; ear-coverts and side of throat (lower submoustachial area) white; chin, mid-throat and central upper breast black, neck side behind ear-coverts pale

olive-grey, sometimes tinged pale pinkish (shading from mantle onto lower breast), lower breast and belly usually mostly darkish, olive-toned grey, lower flanks and vent as posterior upperparts; iris bright red to reddish-brown, sometimes brown; bill black; legs blackish-grey or brownish-grey to brownish-flesh. Sexes similar. Dark morph (“*lugens*”) has ear-coverts and throat side varying from grey to blackish; various intergrades also occur. Juvenile is more olive-toned overall than adult, crown much duller, throat at least partly darkish grey. Race *lochmius* has paler crown than nominate, grey underparts slightly less olive, flanks and vent slightly rufescent; *propinquus* is like previous, but again slightly paler grey below and slightly more rufescent on flanks and vent, but crown more grey-blue, variable (warmer tone and greater contrast between crown and mantle in S of range); *germaini* resembles last, but crown slightly darker, upperparts darker rufescent, the colour continuing behind ear-coverts and onto breast, mid-belly mixed with mid-grey; *monachus* is smaller than others, like last but upper mantle, neck and breast slightly more olive, mid-belly not shot with grey, ear-coverts, moustachial and submoustachial areas and side of throat all blackish. **Voice.** Has repetitive, loud, rich, rather mournful, fluty song incorporating harsh, coarse “wraah” notes and squeaky whistles, like that of a *Turdus* thrush. Calls include a repeated, low, husky “how”.

**Habitat.** Broadleaf evergreen and mixed deciduous forest, secondary growth, scrub (including *Lantana camara*) and grass; to 1525 m.

**Food and Feeding.** Insects; some plant material and seeds. Usually in pairs or in small parties; flocks of up to twelve or more individuals recorded on Hainan. Often associates with other laughingthrushes. Forages in trees and bushes in lower storey. Skulking; heard more often than seen. Mixed pairs (dark morph and “typical” morph) common.

**Breeding.** Mar–Aug; multi-brooded. Nest a loose cup, made of pieces of rattan, bamboo and other leaves and roots, lined with fine and coarse roots, placed in thick bush or bamboo, usually near ground but up to 2–1 m above it. Clutch 3–5 eggs (usually 4 on Hainan), very pale milky blue to bluish-white; in captivity, incubation period 13 days and nestling period 13 days.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common in S China, where recorded in 18 (33%) of 54 surveyed sites, 52 of which are nature reserves; these include Shiwandashan National Nature Reserve and Diding Nature Reserve, where uncommon. Locally common to common in Hong Kong, where population probably of captive origin; frequently traded, at least formerly. Generally fairly common to common in SE Asian range. Common in Khao Yai National Park, in Thailand. Present in Phu Dendin National Biodiversity Conservation Area, in Laos. Common in Tam Dao and Cuc Phuong National Parks and present in Ba Be National Park and Na Hang Nature Reserve, in N Vietnam; present in eleven protected areas in the Annamese lowlands, and scarce in Nam Bai Cat Tien National Park (Cochinchina). Commonly kept in captivity; one of the most popular cagebirds in Vietnam.

**Bibliography.** Berlioz (1930), Bingham (1903), Carey *et al.* (2001), Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paolai (1960, 1962), Corlett (1998), Cox *et al.* (1992), David-Beaulieu (1932, 1939, 1944, 1950), Davidson (1998), Deignan (1963), Delacour & Jabouille (1931a), Dickinson (1970), Duckworth, Davidson & Timmins (1999), Duckworth, Tizard *et al.* (1998), Eames *et al.* (2001), Engelbach (1932), Goes (1999b), Haensel (1988), Hill (2000), Hopwood (1919), Hume & Davison (1878), King & Han Lianxin (1991), King & Liao Weiping (1989), La Touche (1923, 1925–1930), Lê Manh Hùng *et al.* (2002), Lê Xuân Canh *et al.* (1997), Lee Kwok Shing *et al.* (2006), Lekagul & Round (1991), Lewthwaite (1996), Mace (1994), Meyer de Schauensee (1984), Nguyễn Đức Tu *et al.* (2001), Robbins *et al.* (2006), Robinson & Kloss (1919a), Robson (2000), Robson, Eames, Nguyễn C & Truong Van La (1993a), Robson, Eames, Wolstenholfe *et al.* (1989), Round (1999), Smith *et al.* (1943), Smythies (1986), Timmins & Trinh Viet Cuong (1999), Tizard *et al.* (1997), Tordoff *et al.* (2002), Viney *et al.* (1994), Võ Quý (1971), Wickham (1929), Winkendick (1993), Yen Kwokying (1934a), Zheng Zuoxin *et al.* (1983).

## 199. Chestnut-backed Laughingthrush

### *Dryonastes nuchalis*

**French:** Garrulaxe à nuque marron

**Spanish:** Charlatán Nuquipardo

**German:** Rotnackenhäherling

**Other common names:** Ogle's Laughingthrush

**Taxonomy.** *Garrulax nuchalis* Godwin-Austen, 1876, Lhota, Naga Hills, Nagaland, India. Genus traditionally subsumed in *Garrulax*, but differs in some small details of morphology. May form a superspecies with *D. chinensis*, and has been treated as conspecific. Monotypic.

**Distribution.** NE India (SE Arunachal Pradesh S to SE & E Assam and Nagaland) and N Myanmar.

**Descriptive notes.** 23–26 cm. Medium-sized laughingthrush with dark grey-blue crown, chestnut mantle and neck side, and black face and broad mesial stripe offset by whitish from ear-coverts to breast. Bristly lores, upper submoustachial and forehead are black, this colour extending around and behind eye in narrow eyestripe, a few narrow uneven flecks of white above black on forehead; crown dark slate-grey, well demarcated from rufous-chestnut nape, upper mantle and neck side bordering ear-coverts; the shading sharp, to olive-tinged rufescent brown on lower mantle and a shade darker on back to uppertail-covert; upperwing and tail, wing with pale olive-grey tinges; tail distally blackish on outer feathers.

chin, narrow area of central throat and slightly larger area of mid-breast black (some feathers on mid-breast tipped warm brown), ear-coverts to outer throat and lower breast side whitish, shading to buffy pinkish-grey on lower breast and upper belly, to greyer and more olive-brown on flanks and lower belly (same colour as lower upperparts); iris brick-red to purplish-crimson, orbital skin grey; bill black, sometimes dark horn; legs greyish-flesh to brownish. Sexes similar. Juvenile apparently undescribed. **Voice.** Song very like that of *D. chinensis*, includes variety of mellow whistles, alternating between higher and lower short slurred notes, usually a few repetitions of one note type per phrase before changing to another, slightly different type with hardly a pause, e.g. “whit-oo-whit-oo-whit, whééoo-whééoo-whééoo, tiu-whit-tiu tiu-whit-tiu tiu-whit-tiu, whit-no-whit-oo...”. May include some mimicry.

**Habitat.** Second growth, thickets, scrub-jungle, rocky scrub-clad ravines, tall grass, bamboo, overgrown abandoned cultivation, edges of broadleaf evergreen forest; lowlands to 915 m.

**Food and Feeding.** Insects, including ants (Formicidae). Found in small parties, sometimes in company with other laughingthrushes. Forages mainly on ground, and under dense vegetation; skulking.

**Breeding.** Mar–Jul. Nest reportedly a neat and compact cup, outer part made of bracken, internal part of dead leaves and broad grass blades, lined with moss, rootlets and fibres, placed within c. 1 m of ground in dense bush. Clutch 2–3 eggs, usually 3, very pale blue (very rarely white); incubation by both sexes. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in (and responsible for defining) Northern Myanmar Lowlands Secondary Area. Generally uncommon in Myanmar, and in Assam judged locally not uncommon. Few recent records of this species, however, and current status poorly known, at least in part because much of its range is infrequently visited by ornithologists.

**Bibliography.** Ali & Ripley (1972), Anon. (2006d), Berlioz (1930), Butchart & Stattersfield (2004), Choudhury (2000), Collar *et al.* (2001), Grimmett *et al.* (1998), King *et al.* (2001), Rasmussen & Anderton (2005), Robson (2000), Singh (1995), Smythies (1986), Stanford (1935), Stanford & Mayr (1941), Stanford & Ticehurst (1935, 1938), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

## 200. Rufous-vented Laughingthrush

### *Dryonastes gularis*

**French:** Garrulaxe à queue rousse **German:** Roststeiðhäherling **Spanish:** Charlatán Culirrufo  
**Other common names:** Yellow-breasted/Yellow-throated/McClelland's Laughingthrush

**Taxonomy.** *Ianthocincla gularis* McClelland, 1840, Cachar, or possibly Sadiya, Assam, India. Genus traditionally subsumed in *Garrulax*, but differs in some small details of morphology. May form a superspecies with *D. delesserti*, and in the past commonly considered conspecific. Birds from Laos described as a geographical race, *auratus*, but considered inseparable from those elsewhere in species' range. Monotypic.

**Distribution.** SE Bhutan, NE Indian hill states and N Myanmar; also N & C Laos and adjacent N Annam (Vu Quang), in Vietnam.

**Descriptive notes.** 23–25.5 cm. Medium-sized longish-billed skulking laughingthrush, grey on crown and flanks, rusty brown on upperparts and thighs, with black mask and primrose-yellow throat to belly. Crown is dull olive-tinged mid-grey (forehead with yellow tinge), this extending down side of neck onto upper and middle flanks, where colour paler, and shading abruptly into dull chestnut on upperparts and upperwing; tail slaty centrally with bright rufous outer feathers; face mask formed by black of lores extending backwards as short supra-ocular supercilium and cheek patch onto upper ear-coverts; black interramal spot, rest of chin,

throat, submoustachial area and lower ear-coverts to mid-breast and mid-belly primrose-yellow (becoming off-white in museum specimens), lower flanks and vent rufous-tan; iris reddish-brown to bright red, orbital skin and rounded triangular skin patch behind eye ochre-yellow or dark slate (significance of difference unknown); bill dull slaty black to dull blackish-brown, paler base; legs yellow-ochre to bright reddish-yellow. Sexes similar. Juvenile is initially much brighter rufescent overall than adult, with rufous-fringed brown crown, and bright rusty sides and breast. **Voice.** Flocks utter harsh rattling chirrs interspersed with rather nasal, discordant, high-pitched whistled phrases. Possible songs include clear, very sweet, chiming, slightly upslurred and then strongly downslurred whistles, “fwééuuuu”, and more prolonged, elastic-sounding “fwééuuuuéééé” (strongly upslurred near end). Also, indistinct mellow squabbling and chattering notes from flocks.

**Habitat.** Broadleaf evergreen forest, secondary growth, scrub, sometimes bamboo; 90–1220 m in NE India, but reaching 1300 m in Bhutan; 300–1220 m in SE Asia.

**Food and Feeding.** Mostly insects, also berries and seeds. Found in quite vocal flocks of 6–15 and sometimes up to 40–50 individuals: sometimes associates with other laughingthrushes. Forages mostly on ground, occasionally ascends small understorey trees. Scratches among leaf litter. Skulking and very shy.

**Breeding.** Apr–Jul. Nest reportedly a bulky, shallow, rather untidy cup, made of tendrils, twigs, creepers and roots, lined with black fern and moss roots, placed 1–6 m above ground in bush or sapling. Clutch 2–3 eggs, white to very pale blue or pale blue-green. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare in E Bhutan (at W edge of species' range). Status in India poorly understood, but locally not uncommon in Assam and fairly common in Nandapha National Park, in Arunachal Pradesh. Generally local in SE Asian range. Present in Vu Quang Nature Reserve, in Vietnam. Claimed record from SE Bangladesh now withdrawn.

**Bibliography.** Ali & Ripley (1972), Ali *et al.* (1996), Berlioz (1930), Choudhury (2000), Collar (2006), David-Beaulieu (1944), Davidson (1998), Delacour & Jabouille (1931a), Eames *et al.* (2001), Grimmett *et al.* (1998), Hopwood & Mackenzie (1917), King *et al.* (2001), Koeiz (1954), Ludlow & Kinnear (1937, 1944), Mayr (1938), Rasmussen & Anderton (2005), Ripley (1952), Robson (2000), Singh (1995), Smythies (1986), Spierenburg (2005), Stanford (1935), Stanford & Ticehurst (1935, 1938), Stuart Baker (1893, 1901, 1922), Thompson *et al.* (1993).

## 201. Wynaad Laughingthrush

### *Dryonastes delesserti*

**French:** Garrulaxe de Delessert **German:** Rostflankenhäherling **Spanish:** Charlatán de Delessert

**Taxonomy.** *Clateropus*. *Delesserti* Jerdon, 1839, Kotagiri, Nilgiri Hills, India.

Genus traditionally subsumed in *Garrulax*, but differs in some small details of morphology. May form a superspecies with *D. gularis*, and in the past commonly considered conspecific. Monotypic.

**Distribution.** SW India from Goa and Belgaum S to Kerala and W Tamil Nadu.

**Descriptive notes.** 23–26 cm; 78 g. Crown and rear superciliary area to mantle are dark slaty grey, scapulars, back, upperwing-coverts and tertials dull chestnut-brown, shading to rich rufous on uppertail-coverts; tail brownish-black, primaries with dull pale olive-grey fringes; face (lores, supercilium to above eye, cheek and ear-coverts) slightly glossy blackish; chin, submoustachial area and throat white, shading to pale grey on breast, to dull orange-rufous on mid-belly and to rich rufous on lower flanks, thighs and vent; iris red to maroon-brown; upper mandible dark brown or blackish-brown, lower mandible whitish-flesh to

yellowish-flesh; legs pinkish-flesh. Differs from very similar *D. gularis* in having pale lower mandible, darker grey crown and nape, darker brown upperparts and wings, darker and uniform tail (darker than back), paler and less contrasting mask, sparsely feathered straw-coloured or buff-coloured interarmal region and patch at base of lower mandible, white (not yellow) chin to upper belly, and more chestnut lower flanks and belly. Sexes similar. Juvenile is duller on crown than adult, more chestnut above, warmer on breast, iris pinkish-buff, orbital skin paler yellow, legs dusky. Voice. Songs include loud, strident, musical, falling, “tsééurp (repeated irregularly in chorus with other notes), coarser, more clanging “juur-juur-jhéér-jhéér-jhéér-jhéér-jhéér” (note number variable), and slower, more piping “jhéér-jhéér-jhéér”. Song described also as penetrating nasal whistled phrase of 2–4 descending notes, “tree-tree-true”, and flocks heard to give particularly frenzied, discordant series of screeches, squeals and cracked rattles. Calls include metallic, rasping churr and other less distinct low conversational notes.

**Habitat.** Broadleaf evergreen and semi-evergreen forest (including *Strobilanthes*), thorny canebrakes and black cardamom (*Amomum subulatum*) sholas; at 155–1220 m, mostly 455–760 m.

**Food and Feeding.** Mostly insects, also berries and seeds. Found in flocks of 6–15 and sometimes up to 40–50 individuals. Forages mostly on ground; occasionally ascends into small understorey trees. Quite skulking.

**Breeding.** Dec–Sept. Probably co-operative breeder. Nest described as smallish cup and as rather bulky, almost semi-domed cup, made of grass, leaves, weed stems, twigs, creepers and roots, lined with roots, placed within 2 m of ground in bush, tangle of creepers and briars (*Rosa*) or understorey vegetation (including *Strobilanthes*). Clutch 2–4 eggs, usually 2–3, white. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Western Ghats EBA. Uncommon to common throughout range; present in Mudumalai National Park, in Tamil Nadu. In surveys in 1973–1997 found in 15 areas, including five protected areas, namely Sultan’s Battery, Silent Valley, Periyar East, Periyar West and Tenmalai.

**Bibliography.** Ali & Ripley (1972), Berlioz (1930), Collar (2006), Gokula & Vijayan (1997), Grimmett *et al.* (1998), Rasmussen & Anderton (2005), Stattersfield *et al.* (1998), Stuart Baker (1922), Zacharias (1997), Zacharias & Gaston (1993, 1999).

## 202. Blue-crowned Laughingthrush

### *Dryonastes courtoisi*

**French:** Garrulaxe de Courtois **German:** Blaukappenhäherling **Spanish:** Charlatán Coroniazul  
**Other common names:** Courtois’s Laughingthrush

**Taxonomy.** *Garrulax Courtoisi* Ménégau, 1923, Wuyuan, north-eastern Jiangxi, China.

Genus traditionally subsumed in *Garrulax*, but differs in some small details of morphology. Very closely related to, and until recently treated as conspecific with, *D. galbanus*. Isolated population in Simao, in S Yunnan, described as a geographical race, *simaoensis*, on basis solely of yellowish-grey breastband, but this sometimes present in Jiangxi population. Treated as monotypic.

**Distribution.** S & E China: Yunnan (Simao region), and NE Jiangxi (Wuyuan area).

**Descriptive notes.** 24–25 cm. Crown and nape are dull grey-tinged blue, with line of pale cobalt-blue above black bristly forehead; mantle, scapulars, back and tertials ochrous-fawn, outer greater wing-coverts and outer webs of primaries pale bluish-grey; tail ochrous-fawn with bluish-grey basal half, and with broad blackish-brown tips centrally, and broad blackish-brown subterminal marks and whitish tips on outer feathers; face (lores, low forehead, superciliary area to just behind eye, ear-coverts), upper submoustachial area and chin glossy black, cutting sharply to maize-yellow on throat (but border with black chin white), this in turn shading to greyish-olive on breast, breast side and flanks, with mid-belly whitish-yellow, thighs greyish-white, undertail-coverts white; iris reddish; bill black; legs greyish. Differs from very similar *D. galbanus* in having bluer crown and nape, longer and broader black supercilium (creating larger black patch on ear-coverts), darker brown upperparts, blue-grey fringes of primaries, more grey-blue basal half of tail and broader white tail tips, somewhat longer wing. Sexes similar. Juvenile is like adult, but with bare yellow eyering (in captivity, lost after six months). Voice. Flocks call with continuous nervous titling, and much clearer but subdued, quite nasal but pleasant irregular series of “puiui”, “diui”, “dion” or “diew” notes, sometimes louder “diui-tsiu-pi-ju...”.

**Habitat.** Mixed evergreen and deciduous forest and forest patches, and adjacent bushy areas, also clumps of large trees near human settlements. Nestlings fed mainly with insects. Forages in flocks of up to 40 or more individuals. Forages on ground and in bushes and trees. On ground turns leaf litter; on tree trunks picks out invertebrates; feeds among leafy branches, clinging to overhanging foliage of climbing plants, gleaning for insects.

**Feeding.** Apr–Jul, often two broods reared. Colonial, with several nests simultaneously active in small area, cooperative breeder, up to four individuals attending chicks at one nest, at least three seen to feed chicks. Nest an open cup made of twigs and grasses, lined with dry grasses, placed 4–15 m up in tall tree e.g. Chinese sweet gum (*Liquidambar formosa*) and camphor (*Cinnamomum*

*camphora*). In captivity clutch 3–5 eggs, creamy white, incubation period 14 days, nestling period 13–16 days. Red-billed Blue Magpie (*Urocissa erythrorhyncha*) presumably a nest predator, seen chased away from nest vicinity by breeding group.

**Movements.** Disappears from breeding area at Wuyuan in non-breeding period Aug–Mar; whereabouts at that time unknown, but presumed to make short-distance movements into surrounding areas.

**Status and Conservation.** CRITICALLY ENDANGERED. Two geographically widely separated populations. Known from a single area around Wuyuan, in lowland areas mostly close to R Le’an, where stands of tall trees required for nesting remain, with all known sites close to human habitation and one even in a small town; total number of birds in these localities estimated at 150–190. “Small Protected Areas” have been established at various sites around Wuyuan; interference and predation by squirrels (*Sciuridae*) inferred at some colonies, and control measures needed at these in order to prevent breeding failure. Second population, at Simao, in Yunnan, known from three birds collected in 1956, but all trees now cleared from original locality and villager reported that, although common in 1970s, species had not been seen in 1990s. A curious aspect is appearance of this species in European and American bird trade in 1988–1989; individuals were acquired by and distributed to several conservation-oriented zoos and bird gardens in UK, Netherlands, Germany, France and Italy, where they are being bred under consortium arrangements, with total at end of 2006 of 70 individuals (38 males, 27 females and five unknown) in 17 collections, and zoos in USA also hold small populations (total of 36 individuals in ten collections in 2006); also, nine in Hong Kong bird collections. Origin of these traded birds unknown, evidence indicating both Yunnan and Jiangxi, but possibly an undiscovered population was involved.

**Bibliography.** Berlioz (1930), Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paolai (1962), Collar (2006), He Fenqi (2004), He Fenqi & Lin Jiansheng (2006), Hong Yuanhua *et al.* (2003), La Touche (1925–1930), Lindholm (1997), Long *et al.* (1994), Meyer de Schauensee (1984), Oldenettel (1989b, 1998), Pasini *et al.* (1994), Reul-Schneider & Schneider (2006), Schneider & Reul-Schneider (2003), Schneider *et al.* (2002), Wilkinson *et al.* (2004), Zheng Zuoxin & Tang Ruichang (1982).

## 203. Yellow-throated Laughingthrush

### *Dryonastes galbanus*

**French:** Garrulaxe à gorge jaune **German:** Gelbbauchhäherling **Spanish:** Charlatán Goligualdo  
**Other common names:** Austen’s/Yellow-bellied Laughingthrush

**Taxonomy.** *Garrulax galbanus* Godwin-Austen, 1874, Manipur, India.

Genus traditionally subsumed in *Garrulax*, but differs in some small details of morphology. Very closely related to, and until recently treated as conspecific with, *D. courtoisi*. Monotypic.

**Distribution.** NE India (S Assam, Nagaland, Manipur, Mizoram), SE Bangladesh and adjacent W Myanmar.

**Descriptive notes.** 23–24.5 cm; 55–57 g. Superficially similar to *D. gularis*, but smaller and slimmer, with shorter bill, black chin, ochrous rear upperparts, no rufous on underparts, bold white tail tips. Crown and nape are pale greyish, shading on nape through paler grey to ochrous-fawn or olive-tinged pale warm brown on upperparts, wing fringes and tail, latter with broad blackish-brown tips centrally and broad blackish-brown subterminal marks and whitish tips on outer feathers; neat face mask formed by black bristly forehead, lores, short supercilium, ear-coverts, upper submoustachial area and chin; rest of central underside maize-

yellow (fading to whitish in museum specimens), most intense on throat, but breast shaded with greyish-olive, breast side and flanks greyish-olive, thighs pale yellow to yellowish-white (sometimes tinged as flanks), undertail-coverts white; iris brownish-yellow to orange-red, orbital skin below and behind eye blue or pale blue; bill blackish, tip sometimes whitish-horn; legs blackish-grey to pale silvery leaden. Sexes similar. Juvenile has crown blackish. Voice. Poorly documented. Feeble chirping calls from flocks.

**Habitat.** Tall grass mixed with trees and shrubs, outskirts of and more open areas within dense broadleaf evergreen forest, dense scrub, brushwood, open forest, cut-over secondary forest interspersed with tall grass; at 610–1300 m.

**Food and Feeding.** Mostly insects, also small seeds. Found in pairs or in small parties of up to six individuals, sometimes more (as many as 50–80 recorded), often in association with *D. ruficollis*. Forages mainly on ground.

**Breeding.** Apr–Jun in India and Myanmar. Nest a large, roughly made, flattish to deep cup, of grasses, bamboo leaves, creepers, tendrils, fine twigs and moss roots, lined with yellow grass stems, rootlets, fern roots and stems, placed 0.6–3 m above ground in bush, shrub, tangle of wild raspberry (*Rubus*) or creepers. Clutch 2–4 eggs (usually 3 in India; 5 in captivity), pure white or occasionally very pale blue or creamy white; incubation period 13–15 days. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. In India, formerly locally not uncommon in Assam; not uncommon in Nagaland in 1990s, when regularly found on sale as food in markets. Scarce and local in Myanmar.

**Bibliography.** Ali & Ripley (1972), Berlioz (1930), Choudhury (2000, 2001), Collar (2006), Grimmett *et al.* (1998), Hopwood & Mackenzie (1917), Koelz (1954), Long *et al.* (1994), Pasini *et al.* (1994), Rasmussen & Anderton (2005), Ripley (1952), Robson (2000), Smythies (1986), Stuart Baker (1893), Thompson *et al.* (1993).

## 204. White-cheeked Laughingthrush

### *Dryonastes vassali*

**French:** Garrulaxe de Vassal **German:** Schwarzohrhäherling **Spanish:** Charlatán Cariblanco

**Taxonomy.** *Dryonastes vassali* Ogilvie-Grant, 1906, Nhatrang Province, southern Annam, Vietnam. Genus traditionally subsumed in *Garrulax*, but differs in some small details of morphology. Monotypic.

**Distribution.** S Laos, S Vietnam (C & S Annam) and adjacent extreme E Cambodia.

**Descriptive notes.** 26.5–28.5 cm. Medium-sized laughingthrush, pale brown above with dark grey head, buffy below with black mask and bib and white lower ear-coverts. Crown is slaty grey, shading paler on nape and mantle, rest of upperparts slightly ochrous-tinged rufescent brown, lower rump paler and greyer, upperwing medium grey-brown with pale ochre-grey fringing; basal half of tail olive-tinged greyish, distal half blackish-brown, tail tips whitish (buffier on central pair); bristly

flocks can be very noisy, uttering harsh extended rattles and short quick "whi" notes.

**Breeding.** Mar-Jun in Vietnam. Nest ■ cup. No information.

**Movements.** Resident.

**Bibliography.** Bertloz (1936), Brunel (1978), David-Beaulieu (1939, 1950), Davidson *et al.* (1997), Delacour & Jabouille (1931a), Delacour *et al.* (1928), Dickinson (1970), Duckworth & Hedges (1998), Duckworth *et al.* (1998), Eames (1995), Eames & Ericson (1996), Eames, Eve & Tordoff (2001), Eames, Lê Trong Trại & Nguyễn Cu (1995), Engelbach (1932), Hill *et al.* (2001), Robinson & Kloss (1919a), Robson (2000), Robson, Eames, Nguyễn Cu & Truong Van La (1993a, 1993b), Robson, Eames, Wolstencroft *et al.* (1989), Showler, Davidson, Chanthavi Vongkhamheng & Khounmee Salivong (1998), Stattersfield *et al.* (1998), Thewlis, Duckworth *et al.* (1996), Thewlis, Timmins *et al.* (1998).

*Dryonastes ruficollis*

**French:** Garrulaxe à col roux      **German:** Rothalshäherling      **Spanish:** Charlatán Cuellirrufo

**Taxonomy.** *Ianthocincla ruficollis* Jardine and Selby, 1838, Himalayas.

Genus traditionally subsumed in *Garrulax*, but differs in some small details of morphology. Monotypic.

**Distribution.** SC Nepal, Bhutan, all NE Indian states, NE Bangladesh, W, N & NE Myanmar, and adjacent parts of China (ZE Xizang, W Yunnan).

**Descriptive notes.** 22–27 cm; 51–75 g. Medium-sized laughingthrush, cold olive-brown above and below, with black face to breast, rufous neck patch and vent, and black tail. Has mid-crown to nape slaty grey, upperparts, upperwing, belly and flanks dull greyish olive-brown, wing with slightly paler fringes, tail blackish; entire face, including bristly forehead and lores, supercilium, ear-coverts and sub-moustachial area, and chin to breast black; area on neck behind ear-coverts and bordering upper breast light rufous-chestnut, mid-belly, thighs and vent also light rufous-chestnut; iris

ring yellowish; bill brownish-black; legs dark brown to black. Sexes similar. Juvenile is somewhat paler and browner overall than adult. Voice. Song consists of fairly quickly repeated, jolly whistled phrases, "wiwi'wi-whu, whi-yi-ha" etc. (hurried at beginning). Also more prolonged, slurred, scratchy outpourings. Rather high, clear and slightly shrill "krkrkrkkéérkkóókkéérkóó" (starts with a few quick notes, then builds in steeply inflected notes to much higher, louder crescendo, falling again steeply at very end), varied with extra notes either on end or separately. Calls with repeated, rather high, shrill "ch'ya'a" or "cher" and harsh "wh'it" notes and slow short rattles. Sharp, clear, strongly descending, cheeping, "slééér" notes, varied with less sharp notes and a few short guttural trills.

**Habitat.** Broadleaf forest, forest edge, secondary growth, scrub and grass, bamboo-jungle, tall grass and reeds, often along streams, patches of Siam weed (*Chromolaena odorata*), brambles (*Rubus*), cultivation borders, hedgerows, tea gardens. Occurs at 120–1645 m through most of range; 300–2000 m (recorded up to 2200 m) in Bhutan, where highly secretive in summer months and habitat selection then unknown.

**Food and Feeding.** Insects, including ants (Formicidae), also small molluscs; also berries and seeds, including cultivated millet (*Pennisetum glaucum*) and Asian cultivated rice (*Oryza sativa*). Outside breeding season occurs in flocks of up to 30 or more individuals; parties break up in Mar in Bhutan. Forages on ground or among low bushes.

**Breeding.** Mar–Aug. Nest described as a rather compact, deep cup, somewhat untidy externally, made of dry bamboo or other leaves, grasses, roots, weed stems, creeper stems and tendrils, occasionally dry moss and lichen, lined with black or brown rootlets, placed in bush or brambles, usually 1–1.8 m (occasionally up to 6 m) above ground. Clutch 3–4 eggs, almost white with delicate bluish-green tinge or pale milky blue. No other information.

**Movements, Resident.**

**Status and Conservation.** Not globally threatened. Very local in Nepal, where recorded mainly, locally frequently, in Royal Chitwan National Park. Frequent in Bhutan, where present in Thrumshingla National Park. Locally common in India, where uncommon in Kaziranga National Park and rare in Nameri National Park (Assam), and present elsewhere in NE India in (at least) Buxa Tiger Reserve (West Bengal) and Eaglenest Wildlife Sanctuary and Namdapha and Mouling.

National Parks (all Arunachal Pradesh). Uncommon in Myanmar. In China, uncommon in lowlands of SE Xizang and rare in extreme W Yunnan.

Bibliography. Ali & Ripley (1972), Ali *et al.* (1996), Allen *et al.* (1997), Barua & Sharma (1999, 2005), Bertozzi (1930), Betts (1956), Birand & Pawar (2004), Choudhury (2003), Godwin-Austen (1870), Grimm *et al.* (1998), Hopwood & Mackenzie (1917), Hume & Oates (1889), Inskip & Inskip (1991, 1993b), Inskip *et al.* (2000), Katti *et al.* (1992), King *et al.* (2001), Li Dehao *et al.* (1978), Ludlow & Kinnear (1944), Mayr (1938), Meyer de Schauensee (1984), Rasmussen & Anderton (2005), Ripley (1952), Robson (2000), Singh (1995), Smythies (1986), Spiersburg (2005), Stanford & Mayr (1941), Stanford & Ticehurst (1938), Stevens (1923), Stuart Baker (1893), Zheng Zuoxin *et al.* (1983).

*Garrulax castanotis*

**French:** Garrulaxe de Hainan    **German:** Rotwangenhäherling    **Spanish:** Charlatán Carirrufo

**Taxonomy.** *Dryonastes castanotis* Ogilvie-Grant, 1899, Five-finger Mountains, Hainan, China. Formerly treated as conspecific with *G. maesi*. Two subspecies recognized.

### Subspecies and Distribution.

*G. c. varennei* (Delacour, 1926) – E Tonkin (Mt Ba Vi) and N & C Annam, in Vietnam, and adjacent E Laos.

*G. c. castanotis* (Ogilvie-Grant, 1899) – Hainan I (China).

**Descriptive notes.** 28–30.5 cm; 80–115 g. Fairly large, slaty-grey laughingthrush with rufous-chestnut ear-coverts and blackish face. Nominative race has bristly lores and forehead black, this colour extending above eye in short supercilium; forehead dirty dark olive-grey, shading to darkish grey on crown and remaining body plumage; upperwing and tail darker, slaty grey; chin, submoustachial area, throat and breast blackish-brown, elongate ear-coverts rufous-chestnut and forming large circular head-side patch; iris brown to red-brown; bill black; legs greyish. Sexes similar. Juvenile apparently undescribed. Race *varennei* is somewhat larger.

than nominate, with rear supercilium and patch behind ear-coverts white, ear-coverts paler and shorter (hence smaller patch), crown to mantle and lower underparts paler, latter contrasting more with throat and upper breast. VOICE. Loud outbursts of extended cackling, typically combining rapid chattering and repetitive double-note phrases: very like that of *G. mossi* and *G. milloti*.

**Habitat.** Submontane broadleaf evergreen forest, at 400–1700 m.

**Food and Feeding.** Mostly insects. Found in parties of up to ten or more individuals, sometimes associating with other species in bird waves. Forages mainly among leaf litter on ground, but climbs up to investigate danger; flocks move through lower to middle storeys before descending to ground to feed. Foraging habits identical to those of *G. maesi*.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Locally common across range. In Laos, present in Nam Kading National Biodiversity Conservation Area (NBCA), where common in the higher Nam An valley, Nakai-Nam Theun NBCA, where commonest laughingthrush at head of Nam Phao valley and in dry evergreen forest above 1000 m, and in Nakai-Nam Theun Extension, where commonest laughingthrush in two study areas (Nam Kwai and the Ban Nahoua logging road). Present in five protected areas in the Annamese lowlands, in Vietnam.

**Bibliography.** Berlioz (1930), Collar (2006), David-Beaulieu (1944), Davidson (1998), Delacour & Jabouille (1931a), Eames *et al.* (2001), King & Liao Weiping (1989), Meyer de Schauensee (1984), Robson (2000), Round (1999), Showler, Davidson, Khounmee Salivong & Khamkhoun Khounboline (1998), Timmins & Trinh Viet Cuong (1999).

*Garrulax maesi*

**French:** Garrulaxe de Maës      **German:** Maeshäherling      **Spanish:** Charlatán de Maës

**Other common names:** Maes's Laughingthrush

**Taxonomy.** *Dryonastes Maesi* Oustalet, 1890, Tam Dao Mountains, Tonkin, Vietnam.

**Distribution.** SE China (SC Sichuan, extreme NE & SE; Yunnan, N & SE Guizhou, Guangxi, N Guangdong) and N Vietnam (NW & E Tonkin).

**Descriptive notes.** 28–30.5 cm; 107–118 g. Plain dull grey laughingthrush with black face, white behind ear-coverts and dull brownish breast. Forehead and narrow superciliary crown-line are pale grey to whitish-grey, becoming white on rear crown-line, which joins with white of nape side and neck side behind pale grey ear-coverts; rest of crown and upperparts mid-grey with slight brown tinge, rump and uppertail-coverts slightly browner, upperwing and tail darker and browner; bristly lores, short supercilium, cheek and area below (to just behind) eye and chin black, skin forming continuous mass encircling eye and just over top of bill base.

lower throat and upper breast buffy greyish-brown with paler fringes (faint scale appearance), lower breast to vent slightly paler grey than upperparts, lower flanks and undertail-coverts as rump; iris brown to red-brown; bill black; legs greyish. Sexes similar. Juvenile has upperparts mixed with brown, throat and breast grey-brown. Voice. Sudden outbursts of extended, very loud cackling laughter.

typically a few combined of rapid chattering and repeated double-note phrases, often preceded by a few subdued "ow" notes; very similar to that of *G. castanotis* and *G. milleti*.

**Habitat.** Broadleaf evergreen forest, at 380–1700 m.

**Food and Feeding.** No information on diet. Always in flocks of up to ten or more individuals, sometimes in association with bird waves, which may include other laughingthrushes, such as *Dynamis* *hinensis*. Relatively shy and unobtrusive (apart from loud vocalizations). Feeds mainly among leaf litter on ground, but climbs up to investigate danger; flocks move through lower to middle storeys before descending to ground to feed.

**Breeding.** Apr–May in China. No other information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Moderately common in S China, where recorded in 12 (22%) of 54 sites surveyed, 52 of which are nature reserves; these include Shiwandashan National Nature Reserve, where common, and Diding Nature Reserve, where uncommon. Locally common in N Vietnam, where present in Na Mang Nature Reserve and common in Tam Dao National Park.

**Bibliography.** Berlioz (1930), Cheng Tsohsin (1987), Cheng Tsohsin *et al.* (1963), Collar (2006), Delacour & Jabouille (1931a), Duckworth *et al.* (1998), Evans & Timmins (1998), Hill (2000), Huang Qiang, Deng Heli & Mao Ke (1995), Huang Qiang, Huang Yongzhao & Deng Heli (1993), Lê Manh Hùng *et al.* (2002), Lewthwaite (1996), Liu Kezhi *et al.* (1994), Meyer de Schauensee (1984), Robbins *et al.* (2006), Robson (2000), Robson *et al.* (1989), Showler, Davidson, Khounmee Salivong & Khanikhoun Khounbolin (1998), Thewlis *et al.* (1998), Tordoff *et al.* (2002), Wu Zhikang *et al.* (1986), Yen Kwokying (1934a), Zheng Baolai (1988).

## 208. Black-hooded Laughingthrush

### *Garrulax milleti*

**French:** Garrulaxe de Millet **German:** Kapuzenhäherling **Spanish:** Charlatán de Millet  
**Other common names:** Vietnam Laughingthrush

**Taxonomy.** *Garrulax milleti* Robinson and Kloss, 1919, Dalat, Annam, Vietnam.

Two subspecies recognized.

**Subspecies and Distribution.**

*G. m. sweeti* (J. C. Eames, 2002) – SE Laos and C Vietnam (C Annam).

*G. m. milleti* (Robinson & Kloss, 1919) – S Annam, in S Vietnam.

**Descriptive notes.** 28–30 cm. Large black, grey and white laughingthrush. Nominant race has head to nape, ear-coverts and breast glossy blackish, feathers of forehead and above eye pointed, area behind ear-coverts white, shading into pale grey border around clear-cut black of hood, on mantle turning to dark olive-brown of upperparts; upperwings slatier and tail even darker; on belly grey shades darker, into dull olive-brown on flanks, thighs and vent; iris brown to crimson, triangular postorbital patch pale blue; bill black; legs blackish or dull plumbeous. Sexes similar. Juvenile apparently undescribed. Race *sweeti* has greyer, less

brown-tinged, body and darker wings and tail than nominate. Voice. Very loud outbursts of extended rapid cackling laughter, incorporating prolonged, rapid rattling calls, also ticking notes; very like that of *G. strepitans*.

**Habitat.** Broadleaf evergreen forest, at 800–1650 m.

**Food and Feeding.** No information on diet. Found in flocks of 3–10 individuals, sometimes in association with other species, particularly other laughingthrushes, in bird waves. Forages mostly on ground in dense undergrowth, but also ascends trees to middle storey and lower canopy.

**Breeding.** Season May–Jun. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Da Lat Plateau EBA and Kontum Plateau Secondary Area (latter now becomes a full EBA with discovery of *Trochalopteron ngoclinhense* and *Actinodura sodangorum*). Confined to the Da Lat and Di Linh Plateaux in Vietnam, where locally common, and the Central Highlands of Vietnam, where fairly common around Ngoc Linh, and in Xe Kong and Attapu provinces, in Laos. As this species occurs at relatively low altitudes, it is vulnerable to habitat destruction through agricultural encroachment, charcoal-burning and fuelwood collection, particularly as the human population of the area is increasing because of government resettlement programmes. It occurs in a few protected areas, including Dong Ampham National Biodiversity Conservation Area, in Laos, and Ngoc Linh, Kon Ka Kinh, Kon Cha Rang, Thuong Da Nhim and Chu Yang Sin Nature Reserves, in Vietnam; at last-mentioned site, estimated density 0.7 birds/ha, yielding total population for the reserve of 7690.

**Bibliography.** Anon. (2006d), Berlioz (1930), Brunel (1978), Butchart & Stattersfield (2004), Collar (2006), Collar *et al.* (2001), Davidson *et al.* (1997), Delacour & Jabouille (1931a), Eames (1995, 2001, 2002), Eames *et al.* (1992), Hill *et al.* (2001), Robinson & Kloss (1919a), Robson (2000), Robson *et al.* (1993b), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Thewlis *et al.* (1998), Tordoff *et al.* (2000).

## 209. Cambodian Laughingthrush

### *Garrulax ferrarius*

**French:** Garrulaxe du Cambodge **Spanish:** Charlatán de Camboya  
**German:** Kardamomhäherling

**Taxonomy.** *Garrulax ferrarius* Riley, 1930, Khao Kuap [12°25' N 102°50' E], Cambodia. Formerly treated as conspecific with *G. strepitans*, but more closely related to *G. milleti*. Monotypic.

**Distribution.** SW Cambodia.

grey and flanks to vent dull olive-brown; iris dark reddish-brown, orbital skin pale blue; bill black; legs dark grey-horn. Differs from similar *G. milleti* in having hood and breast chocolate-brown (not black), white neck-side patch but no continuous white collar from nape to lower breast, darker upper mantle and lower breast darker, olive-tinged wings and flanks, marginally shorter tail. Sexes similar. Juvenile undescribed. Voice. Utters rapid cackling laughter, very similar to that delivered by *G. milleti*.

**Habitat.** Inhabits broadleaf evergreen forest, occurring from 800 m up to at least 1250 m in Cardamom Mts.

**Food and Feeding.** No information available on diet. Found in flocks of up to ten individuals, sometimes in association with other species in bird waves. Forages mostly on ground in dense undergrowth.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Status under review. Scarce to uncommon in very limited range.

**Bibliography.** Collar (2006), Eames *et al.* (2002), Riley (1940), Robson (2000), Round & Robson (2001), Thomas & Poole (2003).

## 210. White-necked Laughingthrush

### *Garrulax strepitans*

**French:** Garrulaxe bruyant **German:** Weißhalshäherling **Spanish:** Charlatán Cuelliblanco  
**Other common names:** Tickell's/Brown-breasted Laughingthrush

**Taxonomy.** *Garrulax strepitans* Blyth, 1855, "the mountainous interior of the Tenasserim provinces", Myanmar.

Often treated as conspecific with *G. ferrarius*, but that species is now known to be closer to *G. milleti*. Monotypic.

**Distribution.** E Myanmar (including N Tenasserim), N & NW Thailand, adjacent N Laos and S China (S Yunnan).

**Descriptive notes.** 28.5–31.5 cm; 121–142 g. Large dark laughingthrush with rich olive-brown crown, dull dark rufous ear-coverts, blackish-brown face and breast and greyish-white neck sides. Forehead, crown and nape are deep warm olive-brown (forehead sometimes darker), upper mantle greyish, shading to drab olive on back, rump and wing-coverts; upperwing drab olive-slate, tail blackish-grey; bristly lores, preocular supercilium, basal ear-coverts, area under eye to chin and upper throat blackish, shading to blackish-brown on lower throat and breast; white neck side behind ear-coverts merging into pale grey lower half-collar, this sharply offsetting breast-line but merging into dark ochrous-grey underparts, sootier on flanks and vent; iris brown to reddish-chestnut, orbital skin (fairly large patch behind eye) dark slate to black; bill black; legs blackish-maroon. Sexes similar. Juvenile apparently undescribed.

VOICE. Flocks emit sudden, very loud outbursts of cackling laughter, typically combining rapid chattering and repetitive double-note phrases, like that of *G. leucolophus* but faster, incorporating more prolonged, rapid rattling calls; outbursts preceded and interspersed with clicking "tick" or "tek" notes, which serve also as contact calls.

**Habitat.** Broadleaf evergreen forest, at 500–1800 m.

**Food and Feeding.** Few data on diet; presumably largely invertebrates, but pair seen to feed on nectar 9–12 m above ground at top of silk-cotton (*Bombax*) or coral tree (*Erythrina*). Found in large parties, in undergrowth, on ground or in middle storey. Forages mainly in leaf litter, where flocks often join large bird waves. Noisy but shy.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally fairly common in SE Asian range. Present in Doi Chiang Dao and Huai Kha Khaeng Wildlife Sanctuaries and Kaeng Krachan National Park, in Thailand. Apparently rare in China, where on edge of its range in Xishuangbanna prefecture (S Yunnan).

**Bibliography.** Berlioz (1930), Collar (2006), Deignan (1963), Delacour & Jabouille (1931a), Gyldestolpe (1916), Hume & Davison (1878), Lekagul & Round (1991), Lowe (1933), Mace (1991), Meyer de Schauensee (1946, 1984), Peng Yanzhang *et al.* (1979), Riley (1930, 1938), Robson (2000), Smythies (1986), Tizard *et al.* (1997).

ssp pectoralis

ssp munileger

## 211. White-crested Laughingthrush

### *Garrulax leucolophus*

French: Garrulaxe à huppe blanche

Spanish: Charlatán Crestiblanco

German: Weißhaubenhäherling

**Taxonomy.** *Corvus leucolophus* Hardwicke, 1815, mountains above Hardwar, Saharanpur, Uttar Pradesh, India.

Often treated as conspecific with *G. bicolor*. Races form two groups, differing in plumage pattern: W nominate and *patkaicus*, with olive-brown posterior upperparts and clear-cut breast-line, and *E. belangeri* and *diardi*, with chestnut upperparts and more extensive, less well-demarcated white underparts. Four subspecies recognized.

#### Subspecies and Distribution.

*G. l. leucolophus* (Hardwicke, 1815) – S Himachal Pradesh and Nepal E to NE India (Arunachal Pradesh except SE) and adjacent S China (SE Xizang).

*G. l. patkaicus* Reichenow, 1913 – SE Arunachal Pradesh and NE Indian hill states (S of S Brahmaputra), E Bangladesh, Myanmar (except SC, E & SE) and S China (W & SW Yunnan).

*G. l. belangeri* Lesson, 1831 – SC & S Myanmar (including Tenasserim) and W Thailand.

*G. l. diardi* (Lesson, 1831) – SE Myanmar, NW, NE & SE Thailand, Indochina and S China (S & SE Yunnan).

**Descriptive notes.** 26–31 cm; 108–131 g. Large chestnut-and-brown laughingthrush with white hood, crest and breast and broad black mask; long erectile crown feathers frequently raised to form crest. Nominative race has crown white, nape mid-grey (forming grey band when crest lowered), lores, cheek and ear-coverts black (forming broad elongate mask); mantle and back dull rufous-chestnut, shading into olive-brown posteriorly and on upperwing, slatier tail; throat and upper breast white, tinged pale grey at breast side, chestnut of mantle extending across lower breast and merging on upper belly into rufescent olive-brown rest of

underparts; iris brown to dark crimson, orbital skin pale bluish-slate; bill slate-black or horn-black; legs dark slate-lead to blackish-green. Sexes similar, but male may be brighter rufous above. Juvenile has shorter crest and more ashy-brown nape; may be more rufescent above, particularly on wing fringes. Race *patkaicus* is like nominate, but generally has more extensive and slightly darker chestnut on mantle; *belangeri* has entire upperparts below nape rufous-chestnut, black of lores extends narrowly across lower forehead, white of throat and upper breast extends onto belly and merges with rufous-chestnut of flanks and lower belly (rather than being sharply delineated below upper breast), remaining underparts chestnut; *diardi* is like last, but slightly stronger rufous-chestnut above, with pale grey hindcollar, still more extensive white below, to lower belly, with dull rufous-brown on flanks, thighs and vent. VOICES. Very vociferous. Varied sounds from different flock-members combine to produce sudden, very loud outbursts of extended cackling laughter, typically involving rapid chattering and repetitive double-note phrases; outbursts often introduced by a few subdued "ow" or "u-ow" or "u-ah" notes, and often fade out, a single individual continuing to mutter subdued low notes such as staccato, hoarse "ker-wick-erwick". Sometimes less coordinated choruses spring up and peter out in seeming disorder.

**Habitat.** Broadleaf evergreen forest and mixed deciduous forest, disturbed, secondary and regenerating forest, scrub, bamboo-jungle, overgrown abandoned cultivation, plantations and gardens near forest; lowlands to 2135 m, typically below 1600 m.

**Food and Feeding.** Mainly insects, including beetles (of families Buprestidae, Elateridae, Rutelidae, Passalidae and Cerambycidae), and spiders (Araneae), berries and seeds; also small reptiles and flower nectar. Generally in lower to middle storeys. Forages mostly on ground, hacking at earth and tossing aside leaves in search of invertebrates; changes place in bounding hops. Noisy and gregarious at all seasons, in flocks of 6–12, sometimes up to 40, individuals, often associating with other (notably necklaced) laughingthrushes in bird waves; in Bhutan flocks of up to 20 occur Dec–Feb, but generally only up to five Mar–Jul and then up to ten Aug–Nov.

**Breeding.** Feb–Sept throughout main range; multi-brooded. Co-operative breeder. Nest reportedly a large, shallow, rough cup, made of coarse grasses, bamboo or other dead leaves, twigs, roots, moss, creeper, plant twigs, stems and tendrils, lined with rootlets (often black), coarse roots, plant flower stems and leaf stalks, placed c. 1–8–6 m above ground in shrub, bush or low tree. Clutch 2–6 eggs (usually 4–5 in India, 3 in S Myanmar), white or china-white; incubation by both sexes, period c. 14 days; nestlings fed by all group-members, may leave nest long before fully grown; no information on fledging period. Brood parasitism by Chestnut-winged Cuckoo (*Clamator coromandus*), Jacobin Cuckoo (*Clamator jacobinus*) and Large Hawk-cuckoo (*Cuculus sparverioideus*) reported.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally common. Common and widespread in Nepal. In Bhutan abundant in the Sunkosh, C & E valleys, and in foothills, and present in Thrumshingla National Park; probably most abundant at 1000–1600 m, but at 1600–1900 m recorded density of 1 breeding pair/1 km of road. Common and widespread in NE India, where as many as 33–3 birds/km<sup>2</sup> in hill forest in Buxa Tiger Reserve (West Bengal), and present in Eaglenest Wildlife Sanctuary and Namdapha and Mouling National Parks (all Arunachal Pradesh), Kaziranga National Park (Assam), and Nongpui Wildlife Sanctuary and Dampa Tiger Reserve (Mizoram); in W of Indian range, seen intermittently in Rajaji National Park (Uttar Pradesh), disappeared in 1977 from New Forest campus at Dehra Dun, and uncommon in Dehra Dun valley, but common in Corbett National Park (Uttaranchal Pradesh). Locally common in SE Bangladesh. Common across SE Asian range. Common in Khao Yai National Park, in Thailand. Common in Cambodia at least before 1970. Common in Xe Pian National Biodiversity Conservation Area (NBCA), Phou Khaohay, Phou Xang He, Xe Bang Nouan and Dong Hua Sao NBCAs, in Laos, and in various other areas of the country, including part of Nakai-Nam Theun NBCA; and present in Phou Xiang Thong NBCA. In Vietnam, common in Cuc Phuong, Bach Ma and Nam Bai Cat Tien National

Parks, and present in Na Hang Nature Reserve, Chu Yang Sin Nature Reserve, and in twelve protected areas in the Annamese lowlands. Common feral resident in Singapore, originating from escaped captives.

## 212. Black-and-white Laughingthrush

### *Garrulax bicolor*

French: Garrulaxe bicolore

German: Schwarzweißhäherling

Spanish: Charlatán de Sumatra

Other common names: Sumatran Laughingthrush

**Taxonomy.** *G[arrulax]. bicolor* Hartlaub, 1844, western Sumatra.

Formerly treated as conspecific with *G. leucolophus*. Monotypic.

**Distribution.** Sumatra.

**Descriptive notes.** 24–28 cm. Head to breast, including upper lores, is white, with glossy black on forehead and over nares and joining, via lower lores, with black "goggles" and lower ear-coverts; entire rest of plumage sooty brown-black; iris reddish; bill black; legs black, greenish-black or slaty black. Differs from similar *G. leucolophus* (of nominate race) in smaller size, proportionately shorter tail, blackish colour of upperparts and lower underparts, differently shaped black mask with high black forehead, white of crown projecting down in front of eye, and black on ear-coverts much narrower. Sexes similar. Juvenile

is like adult, but with much white admixed on black underparts. Voice. No information.

**Habitat.** Broadleaf evergreen forest, at 750–2000 m; possibly slightly more montane than *G. leucolophus*.

**Food and Feeding.** No information. Probably much as for *G. leucolophus*.

**Breeding.** Dec–Apr. No further information.

**Movements.** Resident.

**Status and Conservation.** VULNERABLE. Avidly persecuted by bird-traders; easily removed from an area by means of trapping with the use of decoys. On Mt Kerinci the species has all but disappeared since 1985, and around the year 2000 the species could be found only at Sipurak, two days' hard walk from nearest road. Evidence that it may be in very serious trouble is that many individuals supposedly of this species now on sale in markets in Sumatra are, in fact, of the continental *G. leucolophus*, rather than of this endemic species. Present in Gunung Leuser National Park.

**Bibliography.** Berlioz (1930), Buij *et al.* (2006), Chasen & Hoogerwerf (1941), Collar (2006), Kloss (1931), van Marle & Voous (1988), Meyer de Schauensee & Ripley (1940a), O'Brien & Kinnaird (1996), Parrot (1907), Robinson & Kloss (1919b, 1920, 1924b), Snouckaert van Schaumburg (1922).

## 213. Lesser Necklaced Laughingthrush

### *Garrulax monileger*

French: Garrulaxe à collier

German: Lätzchenhäherling

Spanish: Charlatán Acollarado Chico

Other common names: Necklaced/Black-necklaced Laughingthrush

**Taxonomy.** *Cinc[losoma]. Monilegera* [sic] Hodgson, 1836, Nepal.

Ten subspecies recognized.

#### Subspecies and Distribution.

*G. m. monileger* (Hodgson, 1836) – WC Nepal E to Bhutan, NE Indian states (except E Arunachal Pradesh and adjacent NE Assam), E Bangladesh, W & C Myanmar and S China (W Yunnan).

*G. m. badius* Ripley, 1948 – NE India (E & SE Arunachal Pradesh and Patkai Range, in E Assam) and extreme N Myanmar.

*G. m. stuarti* Meyer de Schauensee, 1955 – SE Myanmar (including extreme N Tenasserim) and NW Thailand.

*G. m. fuscatus* Stuart Baker, 1918 – NC & C Tenasserim (S Myanmar) and adjacent W Thailand.

*G. m. schauensei* Delacour & Greenway, 1939 – extreme E Myanmar, N Thailand, N Laos and S China (S Yunnan).

On following pages: 214. Greater Necklaced Laughingthrush (*Garrulax pectoralis*); 215. White-throated Laughingthrush (*Garrulax albobularis*); 216. Rufous-crowned Laughingthrush (*Garrulax ruficeps*); 217. Masked Laughingthrush (*Garrulax perspicillatus*); 218. Rufous-fronted Laughingthrush (*Garrulax rufifrons*); 219. Ashy-headed Laughingthrush (*Garrulax cinereifrons*); 220. Sunda Laughingthrush (*Garrulax palliatus*); 221. Black Laughingthrush (*Melanocichla lugubris*); 222. Bare-headed Laughingthrush (*Melanocichla calva*); 223. Spectacled Laughingthrush (*Rhinocichla mitrata*); 224. Chestnut-hooded Laughingthrush (*Rhinocichla treacheri*); 225. Chinese Babax (*Babax lanceolatus*); 226. Giant Babax (*Babax waddelli*); 227. Tibetan Babax (*Babax koslowi*).

## 214. Greater Necklaced Laughingthrush

*Garrulax pectoralis*

**Other common names:** Necklaced/Gorgeted/Black-gorgeted Laughingthrush

*G. n. semitorquatus* Ogilvie-Grant, 1900 – Hainan I.

Very like *G. monileger*, but larger, eye dark, necklace often bolder, dark primary coverts. Nominate race has crown and upperparts olive-tinged mid-brown, hindcollar and upper mantle rufescent, wing fringes and central tail feathers as upperparts but outer primaries fringed greyer, primary coverts darker than rest of wing, outer tail feathers blackish-brown distally with broad white tips; lores and side of forehead whitish to buff, narrow whitish postocular supercilium from eye to above rear of ear-coverts; ear-coverts whitish, variably

**Status and Conservation.** Not globally threatened. Local and uncommon in Nepal, becoming more frequent farther E. Occasionally recorded resident in foothills and C & E valleys in Bhutan, and present in Thrumshingla National Park. Frequent in India, where common in Nameri National Park (Assam), and present elsewhere in NE India in (at least) Buxa Tiger Reserve, in West Bengal, where as many as 25 birds/km<sup>2</sup> in monoculture plantation, also Eaglenest Wildlife Sanctuary and Namdapha and Mouling National Parks, all in Arunachal Pradesh, Balphakram National Park, in Meghalaya, Barail Reserve Forest and Kaziranga National Park (common in latter), in Assam, and Ngengpui Wildlife Sanctuary and Dampa Tiger Reserve, in Mizoram. Fairly common and sometimes abundant in S China, where recorded in 19 (35%) of 54 surveyed sites (of which 52 are nature reserves); widespread but sparse population in Hong Kong of captive origin. Generally uncommon to common in SE Asian range. Present in Kaeng Krachan National Park, in Thailand. Present in the Nakai-Nam Theun National Biodiversity Conservation Area (NBCA) and in Phou

Dendin NBCA, in Laos. Fairly common in Tam Dao National Park, and present in three protected areas in the Annamese lowlands, in Vietnam.

**Bibliography.** Ali & Ripley (1948, 1971), Ali *et al.* (1996), Allen *et al.* (1997), Anon. ## 215. White-throated Laughingthrush

### *Garrulax albogularis*

**French:** Garrulaxe à gorge blanche **Spanish:** Charlatán Gorjiblanco  
**German:** Weißkehhlhäherling  
**Other common names:** Collared Laughingthrush

**Taxonomy.** *Ianthocincla albogularis*. Gould, 1836, Nepal. Closely related to and often treated as conspecific with *G. ruficeps*. Birds from NW Himalayas described as race *whistleri*, those from SW Sichuan (SC China) as *aetus* and those in rest of China as *eous*; distinguishing characters (including mensural differences), however, extremely weak, and naming of geographical races considered unwarranted. Treated as monotypic.

**Distribution.** NE Pakistan (Murree Hills, at least formerly) E to Uttarakhand Pradesh, Nepal, Bhutan and NE India (C Arunachal Pradesh), adjacent S & SE Xizang, SC & S China (W, S & extreme NE Yunnan E through C & NE Sichuan to S Gansu, S Shaanxi and W Hubei; reportedly also in Xining region of E Qinghai, in NC China) and extreme NW Vietnam (W Tonkin).

**Descriptive notes.** 28–30.5 cm; 78–150 g. Rather large, dull brown laughingthrush with white breast, rufescent-buff lower underparts and broad white tail tips. Has lower forehead to eye dull rufous, crown and upperparts rufescent-tinged olive-brown, upperwing and central tail similar but inner primaries fringed olive-greyish, outer primaries fringed pale grey, outer tail feathers with increasingly bold white tips and darker subterminally; lores to cheek blackish, ear-coverts as crown; chin black, throat to upper breast white, band across breast brownish-grey, continuous with but slightly paler and greyer than upperparts,

broadly at breast side, sharply divided from white but shading to ochraceous buff on rest of underparts; iris dull white through blue-grey to dark brown, orbital/facial skin lead-grey; bill horn-brown to black, sometimes paler tip; legs slaty blue to dirty slate. Sexes similar. Juvenile is rather warmer above than adult, with little rufous on forehead, orbital skin greenish-yellow or greenish-olive, less pronounced breastband and whitish mid-belly, bill blackish-olive, darker above, mouth orange-yellow, gape yellow. Voice. Thin shrill wheezy whistles, e.g. "tsu'ueeeee", "hiuuuu", "huiiii" and "hsiii"; gentle "chrrrr", soft "teh" notes and subdued chattering when foraging; harsh forced "chrrr-chrrr-chrrr..." when alarmed. Alternatively, calls described as loud, jarring, squeezed-out, rich, clear, whistled "kleéééééé" (falls slowly and dies away), sometimes ending with purring, and dry hissing "hséééééé". Also, an irregular, nervous chattering, "chit, chit it it it" (usually interspersed quickly among other notes), sometimes run together very rapidly in excited, spluttering purr, "chrrr'r'r'r'r'r'r'r, chrrr'r'r'r". Flock calls become higher and shriller with excitement.

**Habitat.** Broadleaf evergreen forest, deciduous forest and coniferous forest, open secondary growth, scrub and light jungle, occasionally entering fields, at 300–3800 m; breeding mainly above 1200 m, with some descent from highest levels during spells of harsh weather. In Bhutan, replaced at lower elevations by *G. leucolophus*.

**Food and Feeding.** Mainly insects; outside breeding season also berries and seeds. Gregarious, even in breeding season, occurring in flocks of 6–15 individuals; flocks of up to 150 in non-breeding season (mean winter flock size in Bhutan 60, falling to 20 in Mar–Apr); often in association with other species (including other laughingthrushes) in bird waves. Often feeds on ground; also in middle storey, where searches crevices of bark and tears off lumps of moss.

**Breeding.** Mar–Jul. Nest a broad shallow saucer to moderately deep cup, made of coarse dry grasses, dead bamboo or other leaves, ivy twigs with leaves attached, orchid leaves, creepers, twigs, roots, moss and lichen fibres, often well lined with rootlets, moss roots, red and black fern roots and fibres (but sometimes unlined), placed 1–4 m, occasionally up to 6 m, above ground in bush, shrub, sapling or horizontal tree branch. Clutch 2–4 eggs (usually 3 in India), deep dull blue to deep intense greenish-blue; nestlings may leave nest long before full grown. No other information.

**Movements.** Resident and minor partial altitudinal migrant. In Bhutan moves from 1400–3200 m in summer to below 2800 m, occasionally down to 800 m, in winter.

**Status and Conservation.** Not globally threatened. In Pakistan, rare and local, possibly now extinct. Common and widespread in Nepal. Abundant in Bhutan, where present in Thrumshingla National Park. Locally frequent in India, including in Corbett National Park, in Uttarakhand Pradesh, but uncommon in Dehra Dun valley (also Uttarakhand), and seen intermittently in Rajaji National Park, in Uttar Pradesh; although generally very rare in NE hills, very common in vicinity of Eaglenest Wildlife Sanctuary, in Arunachal Pradesh. Fairly common to locally common in China. Uncommon in W Tonkin, in Vietnam.

**Bibliography.** Ali & Ripley (1972), Ali *et al.* (1996), Anon. ## 216. Rufous-crowned Laughingthrush

### *Garrulax ruficeps*

**French:** Garrulaxe à calotte rousse **Spanish:** Charlatán Coronirrufo  
**German:** Rotkappenhäherling

**Taxonomy.** *Garrulax ruficeps* Gould, 1863, Taiwan.

Closely related to and often treated as conspecific with *G. albigularis*. Monotypic.

**Distribution.** Taiwan.

**Descriptive notes.** 27–29 cm. Has crown to nape dull orange-tinged rufous, slightly less intense on nape, where shifting to milky buff-brown, with milky-brown upperwing and tail, outer primary fringes pale brown, tail with large white tips on all except central feathers; small loreal area and upper cheek sparsely feathered blackish, lower cheek and ear-coverts milky buff-brown; chin black, submoustachial area, throat, upper breast and neck sides white, cutting neatly to narrow milky-brown breastband, shading to buffy white on mid-belly to vent and to grey-tinged buffy ochre on flanks and thighs; iris brown or brownish-red, orbital

skin dark grey; bill dusky grey, paler edges and tip. Differs from very similar *G. albigularis* mainly in having forehead to nape dull orange-rufous, upperparts slightly more buff-tinged, breastband much narrower, lower underparts whitish with grey-buff flanks, bill slightly longer, wing and tail shorter, much larger white tail tips. Sexes similar. Juvenile apparently undescribed. Voice. Very similar to that of *G. albigularis*. Weak twittering contact notes and occasional thin, penetrating, shrill, rising "tsuuiiii", "tsuuiii" or "dzuiii".

**Habitat.** Primary forest of oak, fir and cedar, open secondary growth, scrub, occasionally entering fields; at 850–2300 m.

**Food and Feeding.** No information on diet; presumably invertebrates and some vegetable matter. Typically in pairs or in flocks of 15–20 individuals; often in association with Eurasian Jay (*Garrulus glandarius*). Forages in lower to middle strata.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Sparse to fairly common, although habitat relatively restricted. Listed as "Near-threatened" in a national red list.

**Bibliography.** Anon. (2004d), Berlioz (1930), Cheng Tsohsin (1987), Collar (2004, 2006), Hachisuka & Udagawa (1950, 1951), Meyer de Schauensee (1984), Severinghaus & Blackshaw (1976), Yen Chungwei (1990)

## 217. Masked Laughingthrush

### *Garrulax perspicillatus*

**French:** Garrulaxe masqué **German:** Maskenhäherling **Spanish:** Charlatán Enmascarado  
**Other common names:** Black-faced/Spectacled Laughingthrush, Masked Jay-thrush

**Taxonomy.** [*Turdus*] *perspicillatus* J. F. Gmelin, 1789, Amoy, Fujian, China.

Has sometimes been placed in genus *Dryonastes*. Monotypic.

**Distribution.** E & SE China in S Shaanxi, S Shaanxi and N Henan, and from SC Sichuan E to Shanghai, and SE Yunnan E to Fujian and Guangdong; also Vietnam (S to C Annam).

**Descriptive notes.** 28–31.5 cm; 100–132 g. Large laughingthrush, dull plain grey-brown above and greyish-buff below, with greyish head and large blackish mask. Forehead, lores, area above and below eye and ear-coverts are blackish, forehead ochrous mid-grey, shading to mid-grey on rest of crown and drab mouse-brown on upperparts, with rump and uppertail-coverts tinged ochrous; upperwing and tail mid-brown, latter slightly rufescent and with outer feathers shading blackish-brown distally; chin, throat and upper breast pale brownish-grey with vague sooty-brown mottling, mid-breast plain dirty buff, becoming

warmer on belly and rufescent buff on vent, dusky on flanks; iris dark brown to rufous-brown; bill dark horn, blackish-brown or dusky, paler towards tip; legs pale greyish-brown to reddish-brown. Sexes similar. Juvenile has fainter mask, crown and nape browner-tinged, lower mantle and back warmer, throat and breast browner, and wings warmer overall. Voice. Song a noisy set of grunting, chuckling and babbling notes. Typical calls include loud "jhew" or "jhow" notes (often doubled) and harsh chattering.

**Habitat.** Scrub and woodland, cultivated areas, often near villages, thickets, bamboo, reeds, hedgerows; lowlands to 1000 m. Not particularly linked with forest, and in Hong Kong associated with built-up urban areas, parks, villages, farmland and degraded open storage areas.

**Food and Feeding.** Invertebrates, including grasshoppers (Orthoptera), grubs, and snails, also seeds and fruit; group once observed attempting to kill frog. Found in parties, often families, of 6–12 individuals; rather skulking, but often quite noisy. Forages mainly on ground and under thick growth.

**Breeding.** Mar–Aug; multi-brooded. May be co-operative breeder. Nest a large, crude, untidy cup, made of sticks, weed and grass stems, bamboo and other leaves, leaf skeletons, strips of bark, creeper stems, shreds of paper and poultry feathers, lined with mud, roots, twigs, grass and pine needles, placed 1–9 m above ground in thick hedge or bush, brambles (*Rubus*), briars (*Rosa*), bamboo, tall grass, reeds or tree. Clutch 2–4 eggs (usually 3–4 in China), pale buff, suffused with greenish-white or greyish-tan. Sometimes with (and reddish-brown) blotches, sometimes with a blunt end (Guizhou); one nest in China said to contain 3 eggs of this species and 2 of *Pterorhinus saminio*. No other information available.

**Movements.** Resident. Minor altitudinal movements reported require substantiation.

**Status and Conservation.** Not globally threatened. Locally common. In China, at least formerly abundant in Yangtze Valley, and abundant and widespread in Hong Kong. Present in Maershan Nature Reserve, in Guangxi. Generally fairly common in Vietnam, where present in Na Hang Nature Reserve, and in seven protected areas in the Annamese lowlands, occurs also on the outskirts of Bach Ma National Park.

**Bibliography.** Anon. (2004c), Berlioz (1930), Caldwell & Caldwell (1931), Carey *et al.* (2001), Chalmers (1988), Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paolai (1960), Corlett (1998), Cox *et al.* (1992), Eames & Ericson (1996), Eames *et al.* (2001), Herklots (1974), Hill (2000), Jirle & Kjellén (1987), Kaiser (1983), King (1987), Kinnear (1929), La Touche (1906, 1925–1930), Lee Kwok Shing *et al.* (2006), Lewthwaite (1996), Liu Kezhi *et al.* (1994), Liu Rong *et al.* (2002), Meyer de Schauensee (1984), Robson (2000), Robson, Eames, Nguyễn Cu & Truong Van La (1993a), Robson, Eames, Wolstencroft *et al.* (1989), Vaurie (1954b), Viney *et al.* (1994), Vo Quy (1971), Wu Zhikang *et al.* (1986), Yealland (1965), Yen Kwokying (1934a, 1934b), Zhao Xiubi (1994), Zheng Zuoxin & Qian Yanwen (1973).

## 218. Rufous-fronted Laughingthrush

### *Garrulax rufifrons*

**French:** Garrulaxe à front roux **German:** Rotstirnhäherling **Spanish:** Charlatán Frentirrufo  
**Other common names:** Red-fronted Laughingthrush

**Taxonomy.** *Garrulax rufifrons* Lesson, 1831, Mount Salak, west Java.

Two subspecies recognized.

**Subspecies and Distribution.**

*G. r. rufifrons* Lesson, 1831 – W Java.

*G. r. slamatensis* Siebers, 1929 – Mt Selamat, in C Java.

**Descriptive notes.** 27 cm. Fairly large, featureless laughingthrush, greyish-brown with dull chestnut forehead and lores. Nominative race has forehead, lores and area above and below eye dull chestnut, upperparts greyish mid-brown, warmer and darker lower down and on upperwing and tail, with chestnut bases of primaries (visible in flight); uppermost chin dull chestnut, rest of chin, throat and breast pale buffy grey, with faint rufous-chestnut markings on chin and upper throat (sometimes forming faint malar lines), underparts rufescent buff-tinged mid-brown, becoming darker and duller on flanks, lower belly and vent; iris pale

yellow-orange to whitish-yellow, orbital skin dull yellowish-green; bill black, paler tip; legs dark greyish-brown or greenish-brown. Sexes similar. Juvenile apparently undescribed. Race *slamatensis* is slightly rufous-tinged above, strongly washed dull chestnut below and on ear-coverts. **VOICE.** Calls include subdued but harsh “kheh” or “queek” notes, quickly repeated, stressed “hii” and “tii” notes in quick combinations, “hii-tii-hii-hii-tii...”, and, when agitated, nervous chuckling, tinkling “hi-tu-tu-tu-tu-tu...”, or “hihi-hu-hu-hu-hu-hu-hu...” (15–30 or more notes).

**Habitat.** Broadleaf evergreen forest, at 900–2500 m.  
**Food and Feeding.** Berries and insects; insects mostly beetles (Coleoptera, of many families), also mantids, caterpillars, etc. Forages typically in noisy groups of up to 15 individuals; associates also with bird waves.

**Breeding.** May–Jun and Sept in W Java. Nest reportedly a solid cup, placed in horizontal branch fork not far above ground. Clutch 2–3 eggs, blue-green. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Java and Bali Forests EBA. Uncommon. Fairly heavily exploited as a cagebird, which has rendered it uncommon in otherwise moderately secure habitat. Formerly common in Gunung Gede-Pangrango National Park, in W Java, but now rare along main trail, reportedly as a consequence of trapping.

**Bibliography.** Andrew (1985), Anon. (2006d), van Balen (1992), Berlioz (1930), Butchart & Stattersfield (2004), Collar *et al.* (2001), Hoogerwerf (1950a), MacKinnon (1988), Sody (1956), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Voous (1948).

## 219. Ashy-headed Laughingthrush

### *Garrulax cinereifrons*

**French:** Garrulaxe à tête cendrée **German:** Graustirnhäherling **Spanish:** Charlatán Cabecigris

**Taxonomy.** *Garrulax cinereifrons* Blyth, 1851, Sri Lanka.

Monotypic.

**Distribution.** SC & SW Sri Lanka.

**Descriptive notes.** 24–25 cm; 70 g. Rather featureless medium-sized laughingthrush, dull chestnut-brown above and buffy brown below, with dull grey head and pale eye. Lores, crown and neck side are slightly bluish mid-grey, shading on nape to dull chestnut-brown of upperparts, upperwing and tail; wing with pale brown fringes; ear-coverts slightly paler and shinier grey than crown; chin and mid-throat pale buff, shading on lower throat to warm buff, underparts buffy chestnut-brown, slight grey wash on breast, mid-belly paler; iris white, sometimes with greyish, yellowish or reddish tinge; bill black, lower mandible sometimes

paler; legs lead-brown. Sexes similar. Juvenile is warmer overall than adult, with less extensive grey on crown, dull grey iris with dark outer ring. **VOICE.** Continuous, rather high-pitched squeaky notes and harsher churring sounds, harsh “cherrrr” or “chraaaa” or “cheererrrr”, interspersed with sharper “chit” notes and occasionally a higher-pitched “pieu pieu”. Calls described also as very low, “moo, shuffline ‘bur’-rrr” like the snorting of a horse, which may be combined with selection of hoarse, croaked, short staccato squeaks, guffaws, short titters, chuckles, whinnies, sharp metallic notes, and harsh nasal or wheezy mew. Flocks call almost constantly while on the move.

**Habitat.** Shaded understorey of undisturbed broadleaf evergreen forest, bamboo; usually keeps to interior and away from forest edge, although at one site a few were seen in abandoned “chena” cultivation. Found at up to 1200 m, locally 1525 m.

**Food and Feeding.** Caterpillars, bugs (Hemiptera), beetles (Coleoptera), grubs, small snails, fruit and seeds. Food delivered to nest mostly insects, including small caterpillars, moths (Lepidoptera) and grasshoppers (Orthoptera). Forages in monospecific flocks of 4–20 individuals or in bird waves, which often include *Turdoides rufescens*. Foraging flocks often fan out to feed on or near ground in low vegetation and among leaf litter, but also explore mossy fallen tree trunks; main technique is gleaning from leaves.

**Breeding.** Probably mainly Mar–Aug, but male gonadal development recorded in Sept and Nov, and three nests found Nov–Dec, so that all-year breeding likely. Partly social breeder. Nest a large, outwardly untidy mass of twigs and leaves with neat internal cup, externally made of dead leaves and twigs, internally of pliable twigs, rootlets and horsehair lichen, placed up to 5 m above ground in bush or fork of small tree. Clutch 3–4 eggs, turquoise-blue; incubation period 14–15 days; at one nest, full clutch (3 eggs) was laid within 24 hours, suggesting that more than one female was responsible, at least two birds incubated while other five group-members remained within a radius of c. 100 m (smaller than usual ranging area) and, at hatching, at least three attended nest, and all group-members fed chicks in sequence, the last one then brooding them; no information available on nestling period. Nest predation evidently frequent; Sri Lanka Blue Magpie (*Urocissa ornata*) is one suspected culprit.

**Movements.** Resident.

**Status and Conservation.** **VULNERABLE.** Restricted-range species: present in Sri Lanka EBA. Global population estimated at 2500–9999 individuals (probably at lower end of this range) and decreasing; occupied range estimated at 15,800 km<sup>2</sup>. Always judged a low-density species; even so, monospecific flocks in 19th century reported to hold 10–20 individuals, whereas in 1997 none was seen to contain more than six (although later study found mean group size of 7.2). Moreover, of 38 recorded localities, only twelve known to be occupied since 1980, in C & S of range; during survey of more than 200 forest sites in 1991–1996, recorded in only six forests. Nevertheless, still a common member of mixed-species flocks, with 91% of records from such flocks and present in 47% of these flocks. Main threat is extensive clearance and degradation of forests, particularly in wet zone, through logging, fuelwood-gathering, conversion to agriculture and tree plantations, gem-mining, settlement and fires. May be particularly vulnerable to habitat loss and fragmentation, as it is confined to interior of forest blocks and is probably unable to move between isolated patches. Some protected forests continue to be degraded and suffer further fragmentation. A moratorium was passed in 1990 to protect wet-zone forests from logging. The species is legally protected in Sri Lanka. It occurs in several national parks and forest reserves, most notably Sinharaja Forest Reserve.

**Bibliography.** Ali & Ripley (1972), Anon. (2006d), Banks & Banks (1986, 1987), Butchart & Stattersfield (2004), Collar *et al.* (2001), Fleming (1977), Grimmett *et al.* (1998), Harrison (1999), Henry (1998), Hoffmann (1984), Jayarathna *et al.* (2005), Jayasekara *et al.* (2003), Jones *et al.* (1998), Kotagama & Fernando (1994), Kotagama & Goodale (2004), Legge (1880), Phillips (1978), Rasmussen & Anderton (2005), Siriwardhene (2004), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Warakagoda (2003).

## 220. Sunda Laughingthrush

### *Garrulax palliatus*

**French:** Garrulaxe mantelé **German:** Schieferhäherling **Spanish:** Charlatán de la Sonda  
**Other common names:** Grey-and-brown/Catbird Laughingthrush

**Taxonomy.** [*Janthocincla*] *palliatus* Bonaparte, 1850, Sumatra.

Two subspecies recognized.

**Subspecies and Distribution.**

*G. p. palliatus* (Bonaparte, 1850) – Sumatra.

*G. p. schistochlamys* Sharpe, 1888 – N & NC Borneo.

**Descriptive notes.** 24–25 cm. Dull slate-grey medium-sized laughingthrush with black face and dull chestnut back and wings. Nominative race has crown to mantle dull slate-grey, lower mantle, back and scapulars dull chestnut-brown, wing fringes and tail dark brown; bristly lores and cheek black, rear ear-coverts and neck side as mantle; chin to submoustachial area as mantle with sooty-blackish streaks radiating in narrow lines onto mid-grey throat, which shades back to slate-grey on upper breast to lower belly; flanks, thighs and vent dull rufescent-tinged darkish brown; iris deep dull red to brown or grey, fairly large eyering pale

silvery blue; bill black; legs brownish-black or greyish-black. Sexes similar. Juvenile has grey of mantle and back mixed with brown, no streaking on throat, flanks to vent duller, iris dark grey. Race *schistochlamys* has back slate-grey, wing fringes and tail darker than nominate, less black on face and ear-coverts, richer chestnut-tinged flanks to vent. **VOICE.** Flock “songs” start gently with “yieu, yieu” (sometimes interspersed with “ydidit” or “yirdrt”), speeding up into raucous, bubbling, tumbling chaos of sound (screeching, chattering laughter), then easing into either “wikachwakachwikadiwik”, 4–30 quickly repeated “wiku” notes, or flowing “wipuwipuwipuw” etc. Grating, rattling, churring sounds also given, as well as sibilant soft, yelping, contact calls, e.g. “yo, yo, yo...”, “jieu, jieu”, “yuk, yuk”, “jup, jup”, “jip”.

**Habitat.** Broadleaf evergreen forest, sometimes secondary growth but with preference for primary forest; at 850–2200 m in Sumatra, 305–2010 m in Borneo.

**Food and Feeding.** Insects, including beetles (Coleoptera), moths and caterpillars (Lepidoptera), mantids; also seeds and other vegetable matter, including fruits of *Macaranga* and *Mallotus*. Found in flocks of up to twelve or more individuals, sometimes in association with other species, including *Melanerchia calva*. Forages in low vegetation and on ground, flicking over big leaves with bill, and will drop to ground to pick up invertebrates disturbed by tree-shrews (*Tupaia*); generally forages lower than does *Rhinocichla treacheri*. In Mount Kinabalu National Park (N Borneo) hunts moths around lights at dawn.

**Breeding.** Mar–Apr in Sumatra and Dec–Mar in N Borneo (Sabah). Evidence from playback of recorded song suggests group territoriality. Nest a well-made cup of fibres with finer lining material. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Bornean Mountains EBA and Sumatra and Peninsular Malaysia EBA. Fairly common. Occurs in Mount

Kinabalu National Park (Sabah) and Kayan Mentarang National Park (E Kalimantan), in Borneo, and in Gunung Leuser National Park, in Sumatra.

**Bibliography.** Berlioz (1930), Buij *et al.* (2006), Chasen & Hoogerwerf (1941), Davison (1992), Holmes (1997), Kloss (1931), MacKinnon & Phillips (1993), van Marle & Voous (1988), Parrot (1907), Robinson & Kloss (1918, 1924b), Sharpe (1889), Sheldon *et al.* (2001), Smythies & Davison (1999), Stattersfield *et al.* (1998).

## Genus *MELANOCICHLA* Sharpe, 1883

### 221. Black Laughingthrush

#### *Melanocichla lugubris*

French: Garrulaxe noir

German: Trauerh herling

Spanish: Charlat n Negro

**Taxonomy.** *Timalia lugubris* S. M ller, 1836, Sumatra.

Genus traditionally subsumed in *Garrulax*, but exhibits some morphological and vocal differences. Forms a superspecies with *M. calva*, and formerly treated as conspecific. Monotypic.

**Distribution.** Extreme S Thailand, Peninsular Malaysia and Sumatra.

duller than adult, particularly on mantle and wing-coverts, with neck skin dark blue. Voice. Song, typically by at least two birds at once, consists of amazing loud hollow whooping "huup-huup-huup..." and rapid loud "okk-okk-okk-okk...", accompanied by harsh "awh" or "aak" notes; very similar to that of *M. calva*.

**Habitat.** Broadleaf evergreen forest, disturbed forest, forest edge, treefall light-gaps, secondary growth, at 500–1600 m; above 800 m in Peninsular Malaysia.

**Food and Feeding.** Insects, including curculionid and other beetles, ants (Formicidae), grasshoppers and crickets (Orthoptera), and caterpillars; also spiders (Araneae), and some seeds. Forages in pairs or small flocks, sometimes in association with bird waves. Usually close to ground, sometimes up to 9 m in trees. Chisels away at rotten branches to locate food.

**Breeding.** Oct–Apr. One nest was a bulky cup made of vegetable fibres and leaves, loose and ragged outer layer decorated with green moss and bound with roots, epiphyte stems and coarse fibres, and clearly defined, neater inner core and lining of interlaced dried bamboo leaves and blackish fibres probably from dudok palm (*Caryota aequatorialis*), placed c. 2.5 m up in fork of slender sapling on steep bank by jungle stream. Clutch 2 eggs, pale blue with small irregular charcoal spots and smudges. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Sumatra and Peninsular Malaysia EBA. Generally uncommon in S Thailand and Peninsular Malaysia; fairly common at Bukit Fraser (Peninsular Malaysia). Present in Gunung Leuser National Park, in Sumatra.

**Bibliography.** Buij *et al.* (2006), Chasen & Hoogerwerf (1941), Collar (2006), Davison (1992), Gibson-Hill (1950), Harrap (1992), Madoc & Allen (1952), van Marle & Voous (1988), Medway (1972), Medway & Wells (1976), O'Brien & Kinnaird (1996), Robinson (1928), Robson (2000), Sheldon *et al.* (2001), Stattersfield *et al.* (1998).

### 222. Bare-headed Laughingthrush

#### *Melanocichla calva*

French: Garrulaxe chauve

German: Kahlkopfh herling

Spanish: Charlat n Calvo

**Taxonomy.** *Alloctops calvus* Sharpe, 1888, Kinabalu, north Borneo.

Genus traditionally subsumed in *Garrulax*, but exhibits some morphological and vocal differences. Forms a superspecies with *M. lugubris*, and formerly treated as conspecific. Monotypic.

**Distribution.** N Borneo.

yellow. Sexes similar. Juvenile has crown feathered to bill base. Voice. Song a series of 5–22 quite deep, flat-toned, resonant "ooh" notes, fairly evenly delivered but sometimes faltering a little (varied spaces between notes), "ooh-ooh-ooh-ooh-ooh-ooh...", each series repeated after short interval. In duet, "ooh" notes (of presumed male) are combined with strange, comical repeated "yow-yow" or "woh-woh" (from presumed females), the notes being loud and stressed, with high-pitched yelping quavering "ooh-yow-yow-ooh, yow-yow-ooh, yow-yow..."; another accompanying call (from presumed females) is low, harsh, mewling "weeah" given in combination with "ooh" or "ooh" and "yow-yow" notes, e.g. "ooh-yow-yow ooh-yow-yow... weeah-weeah..." or "ooh-ooh-ooh-ooh... weeah-weeah". In flocks constantly gives single bleat as contact. Vocally very similar to *M. lugubris*.

**Descriptive notes.** 25.5–27 cm. Medium-sized blackish laughingthrush with bare bluish-white postocular patch and heavy orange-red bill. Crown, face and upper throat are glossy black, feathers around bill base bristly and those on mid-crown rather sparse; entire rest of plumage dull blackish-grey, tail and inner webs of wing feathers blacker; iris brown to hazel, or blue with brown edge, orbital skin bluish-slate to violet, postocular skin bluish-white; bill orange to reddish-orange; legs brownish-grey to dirty dark green; blue to violet skin on side of throat/neck sometimes visible when vocalizing. Sexes similar. Juvenile is browner and

**Habitat.** Broadleaf evergreen forest, and secondary and disturbed forest, at 800–1800 m.

**Food and Feeding.** Crickets (Orthoptera), cicadas (Cicadidae) and other insects. Found in pairs or small parties, sometimes associating with other species in bird waves. In lower and middle storeys. Creeps about in trees rather sluggishly, foraging especially in columns of vegetation formed by dense vertical creepers around tree trunks, and able almost to free-fall through creepers, using feet to grasp occasionally at perch, in pursuit of falling insects; can hang upside-down like a giant titmouse (Paridae). Gleans ants (Formicidae) from bamboo twigs and larger insects from bamboo leaves.

**Breeding.** Juv in Oct and possible juv in Aug. Evidence from playback of recorded song suggests group territoriality. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Bornean Mountains EBA. Local and uncommon on Mt Kinabalu, and scarce in Kelabit Highlands; common on Mt Dulit.

**Bibliography.** Banks (1937b), Collar (2006), Gore (1968), Harrap (1992), MacKinnon & Phillips (1993), Sharpe (1889), Sheldon *et al.* (2001), Smythies & Davison (1999), Stattersfield *et al.* (1998).

## Genus *RHINOCICHLA* Sharpe, 1883

### 223. Spectacled Laughingthrush

#### *Rhinocichla mitrata*

French: Garrulaxe mitr 

German: Spiegelh herling

Spanish: Charlat n Mitrado

**Other common names:** Chestnut-capped Laughingthrush

**Taxonomy.** *Timalia mitrata* S. M ller, 1836, Sumatra.

Genus traditionally subsumed in *Garrulax*, but exhibits some morphological differences. Forms a superspecies with *R. treacheri*, and hitherto treated as conspecific. Two subspecies recognized.

**Subspecies and Distribution.**

*R. m. major* Robinson & Kloss, 1919 – extreme S Thailand and Peninsular Malaysia.

*R. m. mitrata* (S. M ller, 1836) – Sumatra.

**Descriptive notes.** 22–24 cm. Medium-sized dull grey laughingthrush with yellow bill and legs, white eyering, chestnut on head and vent and bold white wing flash. Nominant race has lores, narial feathering, supercilium and crown chestnut, pointed feathers of forecrown whitish-grey, variable extent of blackish on forehead of face; ear-coverts, neck side, nape and upperparts slightly ochraceous mid-grey, upperwing and tail slightly darker, long white wingpanel on outer primaries, tail with blackish tip; area under white eyering, upper submoustachial area and chin blackish, throat to upper belly mid-grey with ochre tinge

(slightly stronger tinge than on upperparts), flanks darker, lower belly, thighs and vent rufous-chestnut; iris usually red, often red-brown or chestnut, sometimes brown or dark brown, orbital skin white, often with slight grey-blue tinge; bill deep yellow to orange; legs pale yellow to dark orange. Sexes similar. Juvenile is duller and browner than adult, with reduced white streaking on forehead. Race *major* is larger, larger-billed and more strongly ochraceous, notably below, than nominate. Voice. Song fairly subdued but clear and quite shrill, phrases consisting of 3–5 notes, "wi, wu-wi-wu-wi" and "wi, wu-wi" with stressed first note, "wi-wu-wu-wu-wi" with stressed middle note, and "wiu-wu-wu-wi" with rather sharp last note. Calls include sibilant "ju-ju-ju-ju-ju" and "wi-jujujujuju", rapid harsh squirrel-like cackling "wikakakaka", and other low, harsh sounds.

**Habitat.** Broadleaf evergreen forest, forest edge, disturbed and secondary forests and adjoining cultivation, low growth in old rice fields, generally at 900–3200 m; locally down to 500 m in Sumatra.

**Food and Feeding.** Insects, including cassidid and tenebrionid beetles, cockroaches (Blattodea), grasshoppers and crickets (Orthoptera), earwigs (Dermaptera), ants (Formicidae) and caterpillars; also small snails; in addition, fruit, berries and seeds, including chilli (*Capsicum*). Found in pairs or in parties of 4–5 individuals, or in larger flocks, sometimes in association with other species, including other laughingthrushes (and other babblers), in bird waves. Forages in lower and middle storeys, actively working through creepers and thicker foliage, sometimes ascending into taller trees.

**Breeding.** Mar–May in Peninsular Malaysia and Feb–Mar in Sumatra. Nest in one instance a shallow but solid cup of roots and fibres, placed c. 5 m up in tangle of fern fronds hanging from small tree. Clutch 2 eggs, white to deep greenish-blue. No information on incubation and nesting periods. Brood parasitism by Large Hawk-cuckoo (*Cuculus sparveriioides*) occurs in Peninsular Malaysia.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Common in Peninsular Malaysia, where present in Cameron Highlands, Bukit Fraser and Taman Negara National Park. Present in Gunung Leuser National Park, in Sumatra, and common on Mt Kerinci.

**Bibliography.** Buij *et al.* (2006), Chasen & Hoogerwerf (1941), King *et al.* (1975), Madoc (1956), van Marle & Voous (1988), Medway (1972), Medway & Wells (1976), Robinson (1928), Robinson & Kloss (1918, 1924b), Robson (2000).

### 224. Chestnut-hooded Laughingthrush

#### *Rhinocichla treacheri*

French: Garrulaxe de Treacher

German: Kastanienkappenh herling

Spanish: Charlat n de Treacher

**Other common names:** Chestnut-capped Laughingthrush

**Taxonomy.** *Ianthocincla treacheri* Sharpe, 1879, Kinabalu, north Borneo.

Genus traditionally subsumed in *Garrulax*, but exhibits some morphological differences. Forms a superspecies with *R. mitrata*, and hitherto treated as conspecific. Individuals of this species re-

corded in W & SE Borneo (SW Sarawak and SE Kalimantan) apparently not yet assigned to race.

Three subspecies recognized.

#### Subspecies and Distribution.

*R. t. treacheri* (Sharpe, 1879) – N Borneo (Sabah).

*R. t. damnata* Harrison & Hartley, 1934 – NC Borneo (E Sarawak and adjacent NE Kalimantan).

*R. t. griswoldi* J. L. Peters, 1940 – Mt Batu Tibang (Sarawak–Kalimantan border), in C Borneo.

**Descriptive notes.** 22–24 cm. Nominate race has chin, area around bill base, lores, narial feathering and supercilium chestnut, forehead, forecrown and area from chin to below eye darker chestnut, pointed feathers of forecrown greyish-white; neck side and upperparts slightly ochraceous mid-grey, upperwing and tail slightly darker, long white wingpanel on outer primaries, tail with blackish tip; throat, breast and upper belly dull greyish-tinged buffy ochre with dull buffy shaft streaks, flanks greyer, lower belly, thighs and vent rufous-chestnut; iris red to reddish-brown, bright yellow orbital skin below and behind eye; bill yellowish-brown to dull orange; legs dirty yellow to yellow. Differs from very similar *R. mitrata* in having narial feathering, lores and supercilium area slightly paler, clearer chestnut, eyering only on lower and rear edge of eye and bright yellow (not white), chestnut of ear-coverts extending up towards nape, feathers of forecrown greyer, upper malar and chin chestnut, upperparts purer grey, underparts paler ochrous with vague pale shaft streaks. Sexes similar. Juvenile presumably duller than adult. Race *damnata* is like nominate, but breast less streaked and less tinged ochre; *griswoldi* has richer-coloured vent. Voice. Song a fluty, sometimes quite high-noted series of phrases with lower, slightly clicky introductory notes, e.g. "chu-wu, chwi-wi-wi-wi-wiee-wiu-wu" or "ch-wu, ch-wu, chwi-wi-wi-wi-wu" and "ch-wu, chwi-wi"; also "wiu-wu-wu-wi-wi-wee-wu" (rising "wi" notes and descending last 2 notes), and even-pitched "wi, wi-wi-wi-wi" or "wu-tuu-tuu" or "ri-ri-ri-ri" interspersed with "to-we-oh to-we-oh". Has low, harsh, hoarse scolding call notes; contact call within flock a soft, complaining, descending "ah-ah-ah-ah", these notes sometimes given singly.

**Habitat.** Broadleaf evergreen forest, forest edge, disturbed and secondary forests and adjoining cultivation, low growth in old rice fields; generally at 200–2800 m, but reaching 3350 m.

**Food and Feeding.** Grasshoppers and crickets (Orthoptera), ants (Formicidae), earwigs (Dermaptera), caterpillars, moths (Lepidoptera), leafhoppers (Cicadellidae), larval bugs taken and shaken from "spittle", small black beetles (Coleoptera), muscid and non-muscid flies; also small millipedes (Diplopoda); also flowers and fruits of *Rhodamnia*, fruits of *Medinilla* and other melastomes, *Glochidion* and *Mucaranga*, *Trema cannabina*, *Embelia ribes*, *Sambucus*, petals and sepals of introduced *Passiflora edulis*. Creeps and hops within a few metres of ground, but sometimes enters canopy. Forages in parties of 4–5 or more individuals; forms mixed foraging flocks with *Garrulax palliatus* and other birds, tree-shrews (*Tupaia*) and ground-squirrels (*Dremomys*) on ground and with *Sundasciurus* squirrels in canopy. Hops up sloping boughs in manner of a woodpecker (Picidae), but not using tail for support, and picks insects off surface; clings to vertical substrates such as tree-fern trunks. Will forage on forest floor and lawns in manner of *Turdus* thrush, tail held cocked; takes grounded flying ants, and exploits road-killed or vehicle-damaged insects.

**Breeding.** Feb–Apr and Oct. Nest a loose cup of grass stems, tendrils, dead leaves and roots with no inner lining, with outer layer of leaf skeletons, fern leaves and a few feathers, placed c. 3–9 m above ground in long mass of creepers or tangle of ferns hanging from small tree. Clutch 2 eggs, bright greenish-blue or blue. No other information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Abundant in mountains of Borneo. Common in Sabah, including in Mount Kinabalu National Park; present in Kayan Mentarang National Park, in E Kalimantan.

**Bibliography.** Banks (1937b), Davison (1992, 1997a), Finsch (1905), Gore (1968), Holmes (1997), MacKinnon & Phillips (1993), Sharpe (1889), Sheldon *et al.* (2001), Smythies & Davison (1999).

## Genus BABAX David, 1875

### 225. Chinese Babax

#### *Babax lanceolatus*

French: Babaxe lanceolé

German: Streifenbabax

Spanish: Babax Chino

Other common names. Common Babax. Streaked Hill-babbler

**Taxonomy.** *Pterorhinus lanceolatus* J. Verreaux, 1870, "les montagnes du Thibet chinois" = Muping (Paohing), south-east Xizang, China.

Geographically isolated race *woodi* recently suggested to be sufficiently distinctive to warrant species status, but characters appear to be doubtfully strong enough and vocal evidence requires further study; rigorous review required. Four subspecies recognized.

#### Subspecies and Distribution

*B. l. bonvaloti* Oustalet, 1892 – S China (WC Sichuan S to SE Xizang and NW Yunnan).

*B. l. lanceolatus* (J. Verreaux, 1870) – C & S China (S Gansu, S Shaanxi and W Hubei, S to C & N Yunnan, C & E Sichuan and N Guizhou) and NE & C Myanmar.

*B. l. latouchi* Stresemann, 1929 – SE China (S Guizhou, N & C Guangxi, Guangdong, C Fujian).

*B. l. woodi* Finn, 1902 – NE India (SE Mizoram) and W Myanmar (Chin Hills).

**Descriptive notes.** 22–29 cm. 56–105 g. Relatively large, plumaged babax with bold brown and grey streaks above, creamy white with long brown flank streaks below. Nominate race has crown brown with narrow grey edgings, shading on nape, postocular supercilium area, neck side and upperparts to form line of brown streaks with vague pale buffy grey fringes, upperwing and tail dull buffy ochre, and ear-coverts buffy white, bordered below by strong brown submoustachial (rather darker than other breeds), chin to vent creamy off-white, flanks having long mid-brown streaks with darker brown centres, sometimes meeting across belly; iris white to bright orange or pale yellow; bill horn, brown or black; legs horn-grey to grey. Sexes similar. Juvenile is buffier overall than adult, with less prominent streaking (prominent only on nape, mantle and breast), plainer crown, paler ear-coverts, and brown (rather than greyish) outer fringes of wing feathers.

Race *latouchi* is smaller and darker red-brown than nominate, with blackish submoustachial stripe; *bonvaloti* is larger, and darker above; *woodi* has black submoustachial stripe, bolder pattern above, and dark shaft streaks on throat. Voice. Race *woodi* sings with loud full clear whistled "pu-i" or "tchu-wi" phrases, "pu-i, pu-i, pu-i, pu-i, pu-i, pu-i", sometimes hurried to "pu-i-pui-pui-pui...", also as a short, clear, musical, whistled "fiyüwhéé!" ("whéé" higher and louder), sometimes shortened slightly to "fiyüwhéé!" or lengthened to "fiyüwhééah". Calls with quiet chuntering "witchawitcha-witcha-wit" and single "whit" notes when on the move; also, a grouchy "jhu-wit!", and short, excited, chattering rattles, "jwitiitiiti", of variable tempo. Songs of nominate race include clear, quite jolly "wee-wer-choh, whi" or "phi-phu-chu, whi" (first 3 notes clearly spaced and descending, fourth higher or omitted); and calls are harsh thin grating buzzing sounds, and sibilant tittering "jerrt, jerrt, jerrt, chit it it it it..." etc.

**Habitat.** Open broadleaf evergreen forest, forest edge, secondary growth, thin forest and more open hillsides covered with bracken, brambles, grass etc.; scrub and grass, bamboo, sometimes tea plantations. In China occupies wide altitudinal range, 350–4265 m (lowest altitude at Tai Mo Shan, in Hong Kong); recorded only at 1200–2800 m in India and Myanmar (race *woodi*).

**Food and Feeding.** Insects and seeds. Found in pairs or family parties. Forages typically on ground or in low vegetation, occasionally ascending trees to 2–4 m; sometimes even in treetops, especially during mornings and evenings. Shy.

**Breeding.** Mar–Aug. Nest reportedly a loose but well-defined open cup, made of fir, dead bamboo and other leaves, grass stems, weed stalks and bits of fern, lined with rootlets, fine root fibres, tendrils, grass stems and moss, placed 0.6–1.2 m above ground in low thorn or other bush (including tea), brambles or sapling. Clutch 2–6 eggs (usually 3–4 in India and Myanmar, 4–5 in China), dark or deep blue to pure turquoise-blue. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Generally common in China, where recently recorded in Cenwangaoshan Nature Reserve, in Guangxi; apparently rather local in Guangdong, where only recent documented records are from Babaoshan; sparse population in Hong Kong, of captive origin. Status in Mizoram (India) uncertain; no recent published records, but reliable sight records from Phawngpui (Blue Mountain) National Park. Uncommon in Myanmar, but distinctive race *woodi* common in Natmataung National Park.

**Bibliography.** Ali & Ripley (1971), Anon. (2004c), Bangs (1921, 1932), Berlioz (1930), Caldwell & Caldwell (1931), Carey *et al.* (2001), Cheng Tsohsin (1987), Cheng Tsohsin *et al.* (1963), Collar (2006), Deditius (1997), Dowell *et al.* (1997), Grimmer *et al.* (1998), Harington (1909, 1914a), Huang Qiang *et al.* (1993), King (1989a, 1989c), Koelz (1954), La Touche (1923, 1925–1930), Lee Kwok Shing *et al.* (2006), Lewthwaite (1996), Li Dehao (1981), Li Guiyuan *et al.* (1994), Liu Kezhi *et al.* (1994), Meyer de Schauensee (1984), Oustalet (1893), Rasmussen & Anderson (2005), Riley (1926), Robson (2000), Schäfer & Meyer de Schauensee (1938), Smythies (1940, 1949), Stanford & Mayr (1941), Stanford & Ticehurst (1938), Stresemann & Heinrich (1940a), Tan Yaokuang & Cheng Tsohsin (1964), Thet Zaw Naing (2003), Traylor (1967), Vaurie (1972), Venning (1912), Viney *et al.* (1994), Wang Zhijun & Wei Tianhao (1983), Wu Zhikang *et al.* (1986), Yu Zhiwei *et al.* (1986), Zhang Quntan *et al.* (1994), Zheng Zuoxin & Qian Yanwen (1973), Zheng Zuoxin *et al.* (1983).

### 226. Giant Babax

#### *Babax waddelli*

French: Babaxe de Waddell

German: Riesenbabax

Spanish: Babax Gigante

Other common names. Giant Tibetan Babax

**Taxonomy.** *Babax waddelli* Dresser, 1905, Tsangpo Valley, Xizang (Tibet), China.

Proposed race *lumsdeni*, described from Le La, on SE Xizang border with Arunachal Pradesh (NE India), is merged with nominate. Two subspecies recognized.

#### Subspecies and Distribution

*B. w. jomo* Vaurie, 1955 – Gyangze region (N of E Nepal–W Bhutan), in S Xizang (China).

*B. w. waddelli* Dresser, 1905 – Lhasa region and Lhünzhub E to R Yi'ong Zangbo and S to Lhünze (on upper R Subansiri), in SE Xizang.

**Descriptive notes.** 31–33.5 cm; 131–160 g. Nominate race has crown pale grey with narrow rufous-edged brown centres, continuing on postocular supercilium area, neck side and upperparts as long, broad brown and buffy-grey streaks, rather irregular in arrangement and almost all grey on rump; upperwing and tail dull pale brown, wing feathers with broad grey fringes on outer webs; face (lores, supercilium area, cheek and ear-coverts) streaked dirty buff-grey and brown, with slight indication of brown moustachial; chin and submoustachial area to upper breast pale greyish-buff, with dark brown shaft streaks on upper breast, shading on lower breast to belly to rufous-edged dark brown streaks on buff background, fading to plainer, dirtier buffish-grey on lower flanks, thighs and vent; iris greyish-white or silvery to brown, or black (breeding male); bill and legs blackish-brown. Differs from similar *B. lanceolatus* in much larger size, relatively longer bill and longer tail, much paler and greyer base colour above with darker streaks, duller grey-buff and streakier underparts, plain blackish-brown tail, no obvious submoustachial patch. Sexes similar. Juvenile is plainer-headed and warmer-tinted than adult, with dark iris. Race *jomo* is larger, larger-billed and somewhat paler above than nominate, with whitish-grey base colour and with streaks slightly more brownish-black. Voice. Pleasant song a rapid series of quavering whistling notes, similar to that of a *Turdus* thrush. Very loud, harsh and grating, raucous calls.

**Habitat.** Adapted to scrub habitats, in forest edge, bushy deciduous upper edges of coniferous and mixed coniferous broadleaf forests; extensive patches of alpine vegetation consisting of tall bushes and dry scrub over 1.5 m high, especially stands of willow (*Salix*) and thickets of sea-buckthorn (*Hippophae rhamnoides*), prickly oak (*Quercus*), often along watercourses and in valleys; also, more rarely, thorny scrub on rocky slopes, avoids woodland plantations. Found at 2800–4600 m.

**Food and Feeding.** Buckthorn fruit, seeds and small insects. Forages singly, in pairs or in small parties of up to eight individuals; mean group size in forest 5.5 and in scrub 5.4. Sometimes joins

mixed-species feeding flocks, which may include *Ianthocincla maxima*. Forages mainly on ground, often digging in soil, but also ascends to tops of bushes. Typically rather shy and skulking. Lives in groups of 3–8 individuals all year.

**Breeding.** Mar–Jul, sometimes later; but period short, and one brood per year assumed. Co-operative breeder in some cases, with nest attended by all group-members; others attended only by breeding pair. Nest a large, rather rough cup, exterior woven with thicker twigs and peeled bark, interior with thinner twigs and roots of plants, placed 1.8–2.1 m above ground, sometimes lower, between branches in thorn bush, willow tree or sapling; main plants used are *Rosa sericea*, *Berberis hemleyana*, *Cotoneaster divaricatus*, *Sibiraea angustata* and *Salix sclerophylla*. Clutch 2–4 eggs, usually 3 (mean 2.9), deep turquoise-blue; male known to incubate; incubation and nestling periods each 16–18 days. In one study, 75% of clutches produce at least one fledged young; egg predation by Common Magpie (*Pica pica*) recorded.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Southern Tibet EBA. Has been described variously as locally common and rare. Global population currently estimated at 120,000 individuals. Population density of 0.04 birds/ha in forest-edge habitats and of 0.03 birds/ha in bushy-scrub habitats; home ranges of two closely followed family groups were 19.9 ha and 14.8 ha, respectively. Judged presumably declining because of deforestation, although extensive pine and mixed coniferous forests with prickly oak and rhododendron still survive in regions E of Lhasa. Strong dependence on high bushes for nesting leaves species susceptible to vegetation degradation, especially through removal of scrub for firewood around middle R Yalong Zangbo (an area of rapid human development and expansion, and the species' core range). Occurs in Dongjiu Nature Reserve.

**Bibliography.** Ali & Ripley (1971), Anon. (2006d), Berlioz (1930), Butchart & Stattersfield (2004), Cheng Tsohsin (1987), Collar *et al.* (2001), Dresser (1906), Grimmett *et al.* (1998), Lu Xin (2004), Ludlow (1928, 1951), Ludlow & Kinnear (1944), Meinertzhagen (1948), Meyer de Schauensee (1984), Rasmussen & Anderton (2005), Robson (1986), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stuart Baker (1922), Zheng Zuoxin *et al.* (1983).

## 227. Tibetan Babax

### *Babax koslowi*

**French:** Babaxe de Koslov      **German:** Koslowbabax      **Spanish:** Babax de Koslov  
**Other common names:** Koslov's Babax

**Taxonomy.** *Kaznakowia koslowi* Bianchi, 1905. Bar Chu and Dzer Chu, tributaries of the Mekong near Chamdo, northern sector of south-east Xizang, China.

Two subspecies recognized.

**Subspecies and Distribution.**

*B. k. koslowi* (Bianchi, 1905) – SC China (SE Qinghai, E Xizang).

*B. k. yuquensis* Li Dehao & Wang Zuxiang, 1979 – southern sector of SE Xizang.

**Descriptive notes.** 27.5–30 cm; 100–125 g. Dull rufous-streaked babax, in size between *B. lanceolatus* and *B. waddelli*, with greyish throat. Nominate race has crown and upperparts rufous-brown with slightly reflective greyish feather edgings, upperwing and tail pale rufous; lores sooty grey, this colour extending vaguely to above eye; throat pale buffish-grey, underparts rufous-brown, with vague grey streaks on breast, buffish-grey streaks on belly, flanks and vent; iris pale greyish to yellowish; bill blackish; legs dark grey. Sexes similar. Juvenile presumably resembles adult. Race *yuquensis* is completely chestnut-

rufous above and rufous-chestnut below, with uppertail and undertail, and inner and outer webs of primaries, all chestnut-rufous, but feathers of chin, throat and centre of abdomen have pale edges. **VOICE.** Call (perhaps in alarm) a dry scolding rattle.

**Habitat** Juniper forest and scrub, including bush cinquefoil (*Potentilla arbuscula*) and hispid honeysuckle (*Lonicera hispida*), and mixed fir–juniper forest and scrub bordering agricultural land, at c. 3650–4500 m.

**Food and Feeding.** No information on diet. Has been observed in pairs or small parties, feeding on ground and among low vegetation. Typically rather wary. Cocks tail in manner of a thrasher (*Toxostoma*).

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Currently considered Near-threatened. Restricted-range species: present in Eastern Tibet EBA. Very little-known species, occurring in an inaccessible and seldom visited area, but appears to be genuinely rather scarce and localized. Some logging of forest within its range, but the species does not appear to be immediately threatened by habitat loss.

**Bibliography.** Anon. (2006d), Berlioz (1930), Butchart & Stattersfield (2004), Cheng Tsohsin (1987), Collar *et al.* (2001), Lee Tehhow *et al.* (1965), Li Dehao & Wang Zuxiang (1979b), Meyer de Schauensee (1984), Rasmussen & Anderton (2005), Robson (1986, 1993), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Zheng Zuoxin *et al.* (1983).

PLATE 17

inches 5  
cm 13

## Genus GRAMMATOPTILA

Reichenbach, 1850

### 228. Striated Laughingthrush

#### *Grammatoptila striata*

French: Garrulaxe strié German: Streifenhäherling Spanish: Charlatán Estriado

**Taxonomy.** *Garrulus* [sic] *striatus* Vigors, 1831, Naini Tal, Kumaon, Uttar Pradesh, India. Commonly placed in genus *Garrulax*. Five subspecies recognized.

#### Subspecies and Distribution.

*G. s. striata* (Vigors, 1831) – Himachal Pradesh and Uttaranchal Pradesh, in N India.  
*G. s. vibex* (Ripley, 1950) – W & EC Nepal.  
*G. s. sikkimensis* Ticehurst, 1924 – E Nepal E to EC Bhutan.  
*G. s. brahmputra* (Hachisuka, 1953) – E Bhutan, NE India (Arunachal Pradesh), and adjacent S China (SE Xizang) and N Myanmar.  
*G. s. cranbrookii* Kinnear, 1932 – N & NE Myanmar and adjacent S China (NW Yunnan).

**Descriptive notes.** 29.5–34 cm; 123–148 g. Large, bulky laughingthrush, brown with thin white streaks, bushy crest and stout bill. Nominant race has crown chestnut, with feathers long, broad and erectile in floppy crest; upperparts dull rufescent brown with bold white shaft streaks, wing fringes and tail dull rufescent brown; head side from above eye to chin and throat chestnut-chocolate with bold whitish shaft streaks, upper breast and neck side similar but paler, mid-breast to lower underparts buffy with long white streaks, dirty ochrous on lower flanks, thighs and vent; iris brownish-pink to dull brick, orbital skin

plumbeous; bill blackish-brown or dark horn, lower mandible paler; legs dull bluish-slate to greyish-brown. Sexes similar. Juvenile is warmer above than adult, streaks on underparts narrower and fainter. Race *vibex* has upperparts very slightly darker than nominate, underparts darker, shaft streaks on breast and belly narrower; *sikkimensis* is darker still, with less contrast between crown and upperparts, wing fringes and tail more chestnut, shaft streaks below narrower; *brahmputra* is duller-crowned than previous, crown less streaked and with broad blackish-brown lateral crownstripe, paler upperparts with more obvious paler dull rufous-brown to olive-brown fringing, less pronounced streaking, more contrasting breast-feather pattern, less pronounced streaking below; *cranbrookii* is like last, but with broader blackish lateral crownstripe, less obvious streaking on forehead and above eye, duller streaking on rest of head. **Voice.** Song a repeated loud, vibrant, rolling “prrit-you, prrit-pri-pri-u”, described also as “whit, whit, duwhich-whéet-whéewwhu-shitick!” (“duwhich” burry, other main notes steeply slurred), with variants including “krrrrwhit!, kwit-kwit-wheeuw!” (“krrrrwhit!” very burry and upslurred, next 2 notes upslurred, last downslurred). When agitated, emits low grumbling “aawh, aawh, aawh’o aawh, aawh...”. Calls include soft, nervous, quite high-pitched “wer-wer-wer-wer-wer”; “wuh-wuh-wuh-wuh”; “wuh-wuh-wuh-wuh-wuh-wuh”; and gentle, rising “wu-wiw”; also, an emphasized, harsh, upslurred short grumbling “gréip-gréip-gréip...”. **Habitat.** Broadleaf evergreen forest, secondary forest, scrub-jungle, thickets, bamboo and wooded patches around villages; found at 600–3060 m (mostly above c. 1000), upper limit coinciding with that of cool broadleaf forest.

**Food and Feeding.** Insects, including beetles (Coleoptera); berries and seeds, including bramble (*Rubus lineatus*), aromatic wintergreens (*Gaultheria*), *Maesa* and *Embelia*, flowers of certain vervains (*Clerodendron*) and rhododendron, and gelatinous lichen. More arboreal than most laughingthrushes, foraging mainly in middle storey to lower canopy, feeding in canopy of tall trees as well as in lower branches and undergrowth. Found singly, in pairs or in parties of 5–8 individuals, often in association with other laughingthrushes and often at fruiting trees (where up to 50 recorded together).

**Breeding.** Apr–Aug. Nest a broad, usually shallow, strongly made cup, of coarse grasses, twigs, creeper stems, rootlets, dead leaves, green moss and green fern fronds, lined with coarse roots, fine black roots and dry grasses, placed 1–6 m above ground in sapling, branches of larger tree or among climbing plants. Clutch 2–3 eggs (usually 2 in India), very pale greenish-blue or bluish-green, sometimes almost white, usually unmarked but sometimes a few very dark brownish-red specks; incubation by both sexes. No other information.

**Movements.** Resident; alleged altitudinal movements in winter near Dehra Dun (N India) require substantiation.

**Status and Conservation.** Not globally threatened. Locally common in Nepal. Abundant and widespread in Bhutan, where density of 5 territories/km of road recorded at 1600–1900 m, and present in Thrumshingla National Park. Locally common in India, where present on New Forest campus at Dehra Dun and uncommon in Dehra Dun valley (Uttaranchal), in Buxa Tiger Reserve (West Bengal), and in Eaglenest Wildlife Sanctuary and Mouling National Park (Arunachal Pradesh). Uncommon to locally common in Myanmar. In China, apparently rare in Gaoligongshan range, in Yunnan.

**Bibliography.** Ali & Ripley (1972), Ali *et al.* (1996), Allen *et al.* (1997), Birand & Pawar (2004), Cai Qikai *et al.* (1977), Cheng Tsohsin (1987), Gaston (1989), Gaston *et al.* (1994), Grimmett *et al.* (1998), Hopwood & Mackenzie (1917), Hume & Oates (1889), Inskipp & Inskipp (1991, 1993b), Inskipp *et al.* (2000), Islam (1993), Katti *et al.* (1992), King *et al.* (2001), Kinnear (1934), Ludlow (1951), Ludlow & Kinnear (1944), Martens & Eck (1995), Meyer de Schauensee (1984), Mohan (1997), Rasmussen & Anderson (2005), Ripley (1961), Robson (1986, 2000), Singh, A.P. (2000), Singh, P. (1995), Smythies (1940, 1949), Stanford (1941), Stanford & Mayr (1941), Stanford & Ticehurst (1938), Stevens (1914, 1923), Ticehurst (1939), Zheng Zuoxin *et al.* (1983).

## Genus STACTOCICHLA Sharpe, 1883

### 229. Spot-breasted Laughingthrush

#### *Stactocichla merulina*

French: Garrulaxe à poitrine tachetée German: Fleckenhäherling Spanish: Charlatán Pechipinto  
Other common names: Spotted-breasted Laughingthrush

**Taxonomy.** *Garrulax merulinus* Blyth, 1851, Cherrapunji, Khasi Hills, Assam [= Meghalaya], India.

Genus usually merged into *Garrulax*. Until recently regarded as conspecific with *S. annamensis*. Proposed race *toxostomina* (from Manipur, in NE India) considered inseparable from nominate. Three subspecies recognized.

#### Subspecies and Distribution.

*S. m. merulina* (Blyth, 1851) – NE India (SE Arunachal Pradesh S to Meghalaya, Mizoram and Manipur), W & N Myanmar and S China (W Yunnan).  
*S. m. laoensis* (Meyer de Schauensee, 1938) – NW Thailand.  
*S. m. obscura* (Delacour & Jabouille, 1930) – SE Yunnan (China), N Laos and N Vietnam (N Tonkin).

**Descriptive notes.** 25–26 cm. Medium-sized brown laughingthrush with pronounced blackish-brown spots on buffish-white throat and breast. Nominant race has crown and upperparts, including head side (lower submoustachial area, cheek, ear-coverts), neck side, upwiring and tail, rich olive-toned brown, narrow buff postocular streak; lores and upper submoustachial stripe dark brown, malar line of dark brown streaks; chin to breast buff with broad dark brown streaks (tending to align as longer stripes), buff continuing to lower belly but shading to plain brown with slight ochre tinge on flanks, vent rusty; iris pale yellowish to pale reddish-brown, orbital skin pale leaden-grey; bill dark horn-brown, greyish on lower mandible; legs pale brown to dark brown. Sexes similar. Juvenile is more rufous above and on flanks, wings and tail than adult, iris brown. Race *laoensis* is like nominate, but streaks on underparts blacker and more separate, buff ground colour paler; *obscura* is slightly darker above and on face, richer buff below, with heavier, blacker spotting on breast. **Voice.** Song loud, rich and melodious, a remarkable, prolonged, rambling series of rich musical phrases, with much mimicry; recalls that of *Dryonastes chinensis* but much richer and more varied, lacking harsh notes and squeaky whistles. Many phrases consist of clear, human-like whistles in slightly off-key melody.

**Habitat.** Understorey shrubbery and edge of broadleaf evergreen forest, bamboo, densely overgrown abandoned cultivation, dense secondary growth and scrub; at 800–2000 m.

**Food and Feeding.** No information on diet. Found singly, in pairs or in family groups. Forages on or near ground; unobtrusive, shy and very skulking.

**Breeding.** Apr–Jul. Nest described as a fairly strong and compact, rather shallow cup, made of moss, roots, grass, leaves and fern fronds, lined with rootlets of ferns, moss and other plants, occasionally fine creeper stems, fine twigs and tendrils, placed low down (often only slightly above ground) in undergrowth of ferns or brambles (*Rubus*), in thick shrub or deep inside bamboo clump. Clutch 2–3 eggs, generally 2, pale blue to green-tinged blue; incubation by both sexes. No other information.

#### Movements. Resident.

**Status and Conservation.** Not globally threatened. Rather uncommon to scarce. Generally uncommon in India, but locally not uncommon in Assam; rare in Namdapha National Park, in Arunachal Pradesh. Rare in marginal range in China. Generally scarce to uncommon in SE Asian range. Rare in Fan Si Pan National Park and present in Pu Mat Nature Reserve, in Vietnam.

**Bibliography.** Ali & Ripley (1972), Berlioz (1930), Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paolai (1960), Choudhury (2000), Collar (2006), David-Beaulieu (1944), Davidson (1998), Deignan (1963), Delacour & Jabouille (1930, 1931a), Eames (1995), Eames *et al.* (2001), Godwin-Austen (1874), Grimmett *et al.* (1998), Hopwood & Mackenzie (1917), Hume (1888), King *et al.* (2001), Koelz (1954), Lekagul & Round (1991), Mayr (1938), Meyer de Schauensee (1984), Rasmussen & Anderson (2005), Robson (2000), Showler, Davidson, Khounme Saliwong & Khamkhoun Khounhohline (1998), Singh (1995), Smythies (1986), Stanford & Ticehurst (1935), Thevlis *et al.* (1998), Vogel *et al.* (2003).

### 230. Orange-breasted Laughingthrush

#### *Stactocichla annamensis*

French: Garrulaxe du Langbian German: Orangebrusthäherling Spanish: Charlatán Pechinaranja

**Taxonomy.** *Stactocichla merulina annamensis* Robinson and Kloss, 1919, Dran [11°49' N, 108°38' E], Annam, Vietnam.

Genus usually merged into *Garrulax*. Until recently regarded as conspecific with *S. merulina*. Monotypic.

#### Distribution. S Annam, in S Vietnam.

**Descriptive notes.** 24–25 cm. Medium-sized laughingthrush with brown upperparts and flanks, blackish throat, orange-rufous supercilium and underparts with neatly black-streaked breast. Has crown to scapulars and rump, including ear-coverts and neck side, rich olive-toned brown, uppertail-coverts a shade paler, upwiring and tail a shade darker (but light-dependent); bristly lores and forehead black, this colour extending just above and below eye and contiguous with blackish

On following pages: 231. Chinese Hwamei (*Leucodioptron canorum*); 232. Taiwan Hwamei (*Leucodioptron taewanum*); 233. Kerala Laughingthrush (*Strophocincla fairbanki*); 234. Black-chinned Laughingthrush (*Strophocincla caehimans*); 235. Bhutan Laughingthrush (*Strophocincla imbricata*); 236. Streaked Laughingthrush (*Strophocincla lineata*); 237. Striped Laughingthrush (*Strophocincla virgata*); 238. White-browed Laughingthrush (*Pterorhinus sannyio*); 239. Plain Laughingthrush (*Pterorhinus davidi*); 240. Snowy-cheeked Laughingthrush (*Ianthocincla sukatschewi*); 241. Moustached Laughingthrush (*Ianthocincla cineracea*); 242. Rufous-chinned Laughingthrush (*Ianthocincla rufogularis*); 243. Chestnut-eared Laughingthrush (*Ianthocincla konkakinhensis*); 244. Barred Laughingthrush (*Ianthocincla lunulata*); 245. White-speckled Laughingthrush (*Ianthocincla bieti*); 246. Giant Laughingthrush (*Ianthocincla maxima*); 247. Spotted Laughingthrush (*Ianthocincla ocellata*).

submoustachial area, chin and throat; pale orange-rufous area on forehead (immediately above black) and extending as postocular supercilium; breast orange-rufous with neat black streaks (narrower and clearer than in *S. merulina*), mid-belly plain orange-rufous, becoming paler on vent, with flanks and thighs rufous-brown; iris brown, orbital skin black; upper mandible blackish, lower mandible dark grey; legs dark brown to bluish-grey. Sexes similar. Juvenile apparently undescribed. Voice. Song loud, rich and melodious, of rich musical phrases in prolonged rambling series, with much mimicry; very like that of *S. merulina*.

**Habitat.** Undergrowth and edge of broadleaf evergreen forest, bamboo clumps, densely overgrown abandoned cultivation, treefall light-gaps in closed-canopy evergreen forest, dense secondary growth and scrub; at 915–1510 m.

**Food and Feeding.** No information on diet. Forages singly, in pairs or in family groups, on or near ground, unobtrusive, shy and very skulking.

**Breeding.** Three specimens with regressing gonads in Mar. No other information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Uncommon to locally common within very small range. Present in Thuong Da Nhim and Chu Yang Sin Nature Reserves.

**Bibliography.** Berlioz (1930), Collar (2006), David-Beaulieu (1944), Delacour & Jabouille (1927, 1930, 1931a), Farnes (1995), Robinson & Kloss (1919a), Robson (2000), Robson *et al.* (1993b).

## Genus *LEUCODIOPTRON* Bonaparte, 1854

### 231. Chinese Hwamei

#### *Leucodioptron canorum*

**French:** Garrulaxe hoamy **German:** China-Augenbrauenhäherling **Spanish:** Charlatán Canoro  
**Other common names:** Melodious Laughingthrush, Chinese Thrush, Spectacled Jay-thrush

**Taxonomy.** [*Turdus*] *Canorus* Linnaeus, 1758, Amoy, Fujian, China.

Genus previously subsumed into *Garrulax*. Formerly treated as conspecific with *L. taewanum*, but differs significantly in plumage, morphometrics and genetics, and to some degree in voice. Two subspecies recognized.

**Subspecies and Distribution.**

*L. c. canorum* (Linnaeus, 1758) – SE China from S Gansu, S Shaanxi, Hubei, SE Henan and S Jiangsu to Yunnan (except NW), Guangxi and Guangdong, also E Laos and Vietnam (S to NC Annam).

*L. c. owstoni* (Rothschild, 1903) – Hainan I.

**Descriptive notes.** 21–24 cm: 49–75 g. Relatively plain medium-sized laughingthrush, warm brown with darker streaking on head and breast, and with bold white eyering and postocular stripe. Crown is warm ochre-tinged brown with vague darker brown streaks, upperparts similar but streaking very diffuse, fringes of wing feathers warm ochre-tinged brown, tail darkish brown; bold white eyering and postocular streak, ear-coverts plain dull ochreous-brown; lores, cheek, neck side and chin to upper breast warm brownish-ochre with narrow dark brown streaks, lower breast, flanks, thighs and vent warm brownish-ochre, mid-belly dull grey; iris brown to pale greenish-yellow; bill dusky yellow; legs dusky yellowish to dark flesh. Sexes similar. Juvenile has less streaking on head and breast than adult. Races very similar: *owstoni* is marginally more olive above and on ear-coverts than nominate. Voice. Song by male rich, varied, quite high-pitched, including regular repetition and some mimicry; usually starts slowly, then increases in volume and pitch (may repeat this during single outburst); faster and higher-pitched than song of *Dryonastes chinensis*, reminiscent of that of *Pellorneum albiventre*. Female has series of monotonous calls which, given in earshot of male, prompt song from him.

**Habitat.** Shrublands, open woodland, thickets, scrub, bamboo, reeds, tall grass, gardens, vacant lots in urban areas; up to 1800 m in China, to 1450 m in SE Asia.

**Food and Feeding.** Mainly insects, including locust eggs (Locustidae) and ants (Formicidae); also fruit, seeds and sometimes cultivated maize (*Zea*) and other grain. In Hong Kong study, in Aug–May, 86% of 72 faecal samples contained insects and 81% contained fruit (of 14 plant taxa, with a further two seen being eaten). Found singly, in pairs or in small parties. Searches for food on ground.

**Breeding.** Mar–Aug; multi-brooded. Nest is reported to be a large cup, outwardly rough but with well-defined walls, made of leaves (including oak and bamboo), grasses, stems, ferns, creepers, roots and tendrils, lined with tendrils, rootlets, grass, leaves, thin twigs, pieces of vine and moss, placed in grass, bush (including holly and tea), small tree or on tree stump, from ground to 2 m up. Clutch 2–5 eggs, usually 3–4, pale blue to deep bluish-green, reportedly occasionally with large white spots; incubation mainly by female, period 12 days; no information available on fledging period.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. CITES II. Relatively common in Chinese range. In recent fieldwork in S China found at 36 sites (67% of those visited), including Shiwandashan National Nature Reserve (Guangxi), where rare, common and widespread in Hong Kong, where population has recovered strongly with reduction in trapping, and possibly with spread of shrublands. Commonly fairly common in SE Asian range. Few records from Laos, but possibly largely under-recorded owing to low interest in scrub habitat. Under very heavy trapping pressure in Vietnam, where present in Ba Be National Park and Na Hang Nature Reserve, and in five protected areas in the Annamese Lowlands (BA). Local population also in Singapore (uncommon), established outside natural range also in Taiwan and Japan (three main centres of population).

**Bibliography.** Andersson (2001), Anon. (2004d), Bangs & Peters (1928), Berlioz (1930), Caldwell & Caldwell (1931), Carey *et al.* (2001), Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paolai (1960, 1962), Cheng Tsohsin *et al.* (1963), Collar (2006), Corlett (1998), Cox *et al.* (1992), David-Beaulieu (1944, 1950), Davidson (1998), Delacour & Jabouille (1931a), Dowell *et al.* (1997), Duckworth *et al.* (2002), Eames *et al.* (2001), Fang Woeihong (2005), Fischer (1995), Herklots (1974), Hill (2000), Huang Qiang, Deng Heli & Mao Ke (1995), Huang Qiang, Huang Yongzhao & Deng Heli (1993), Kawakami & Yamaguchi (2004), King (1987), King & Liao Weiping (1989), King & Zheng Guangmei (1988), Kinnear (1929), Koh Chaonien & Lee Peifen (2003), La Touche (1899, 1906, 1923, 1925–1930), Lê Manh Hùng *et al.* (2002), Lee Kwok Shing *et al.* (2006), Li Guiyuan, Liu Liangcai *et al.* (1976), Li Guiyuan, Zhang Qingmao, Luo Jiaye *et al.* (1994), Li Guiyuan, Zhang Qingmao & Wen Anxiang (1993), Li Shoushien *et al.* (2006), Liu Kezhi *et al.* (1994), McCarthy (2006), Meyer de Schauensee (1984), Nguyễn Đức Tu *et al.* (2001), Robbins *et al.* (2006), Robson (2000), Robson, Eames, Nguyễn Cu & Truong Van La (1993a), Robson, Eames, Wolstencroft *et al.* (1989), Round (1999), Sato (2000), Schleussner (1983), Stresemann (1923c), Traylor (1967), Tu Hsiao-wei (2003), Tu Hsiao-wei & Severinghaus (2004), Wu Zhikang *et al.* (1986), Yeo (1969), Yu Zhiwei *et al.* (1986), Zhang Keyin *et al.* (2003), Zhang Quntan *et al.* (1994), Zhao Xiubi (1994), Zheng Zuoxin & Qian Yanwen (1973), Zheng Zuoxin *et al.* (1983), Zhu Xi & Fan Houde (1995).

### 232. Taiwan Hwamei

#### *Leucodioptron taewanum*

**French:** Garrulaxe de Taiwan

**German:** Taiwan-Augenbrauenhäherling

**Spanish:** Charlatán de Formosa

**Taxonomy.** *Garrulax taewanus* Swinhoe, 1859, Taiwan.

Genus previously subsumed into *Garrulax*. Formerly treated as conspecific with *L. canorum*, but differs significantly in plumage, morphometrics and genetics, and to some degree in voice. Monotypic.

**Distribution.** Taiwan.

**Descriptive notes.** 21–24 cm. Crown is cold ochre-tinged buff with dark brown streaks, shading on mantle to buffish-grey with soft-edged irregular streaking; rest of upperparts greyish-tinged mid-brown, upperwing warmer ochre-tinged brown, tail darkish brown with vague darker barring; lores, cheek and ear-coverts buffy brown with slight dappled effect; chin to upper breast dull ochreous-buff with narrow dark brown streaks, shading on lower breast, flanks, thighs and vent to plain greyish-buff and on belly to vague pale grey; iris greyish, orbital skin yellowish; bill and legs yellowish. Differs from very similar *L.*

*canorum* in having narrower eyering, no postocular streak, coloration above greyer with broader, darker streaking, below pale dirty buff with duller flanks and vent, tail slightly longer. Sexes similar. Juvenile has less streaking on head and breast than adult. Voice. Songs rich and varied, quite high-pitched, resemble those of *L. canorum* but less complex, containing significantly fewer syllable types, fewer syllable changes, smaller syntax combinations and more syllable repeats per song.

**Habitat.** Secondary vegetation, upper undergrowth and lower tree strata in foothill and submontane *Ficus–Machilus* and *Machilus–Castanopsis* zones, to 1200 m.

**Food and Feeding.** Insects and seeds found in stomachs. Forages singly, in pairs or in small parties, on ground.

**Breeding.** Mar–Aug. Nest a rough cup of leaves (including *Miscanthus* and bamboo), twigs, roots and coarse grasses, rather loosely bound together with tendrils and sometimes with lining of pine needles, placed up to 2 m above ground in bush (including *Acacia* and *Miscanthus*). Clutch 2–3 eggs, turquoise to greenish-blue; incubation mainly by female, period 12 days; no information on fledging period.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Fairly common to common. Formerly abundant, but has suffered from extensive habitat clearance in lower parts of elevational zone, coupled with considerable hunting and trapping pressure. Categorized as “Endangered” in a national red list. Now threatened by interbreeding with *L. canorum*; latter being imported in high volume into Taiwan for its singing abilities, and individuals, once discovered to be female, are usually released, thereby becoming available to breed with males of present species.

**Bibliography.** Berlioz (1930), Cheng Tsohsin (1987), Collar (2006), Fang Woeihong (2005), Hachisuka & Udagawa (1950, 1951), Li Shoushien *et al.* (2006), McCarthy (2006), Meyer de Schauensee (1984), Severinghaus & Blackshaw (1976), Smith & Yu Honsen (1992), Tu Hsiao-wei (2003), Yen Chungwei (1990).

## Genus *STROPHOCINCLA* Wolters, 1980

### 233. Kerala Laughingthrush

#### *Strophocincla fairbanki*

**French:** Garrulaxe de Fairbank **German:** Graubrusthäherling **Spanish:** Charlatán de Kerala

**Other common names:** Grey-breasted Laughingthrush (when combined in a species with race *jerdoni* of *S. cachinnans*)

**Taxonomy.** *Trochalopteron Fairbanki* Blanford, 1869, Palni Hills, southern India.

Genus usually subsumed in *Garrulax*. Species sometimes placed in genus *Trochalopteron*. Has until recently often been combined in a species with race *jerdoni* of *S. cachinnans*; further study required. Two subspecies currently recognized.

**Subspecies and Distribution.**

*S. f. fairbanki* (Blanford, 1869) – SE Kerala and SW Tamil Nadu (N of c. 9° N), in SW India.

*S. f. meridionalis* (Blanford, 1880) – S Kerala and S Tamil Nadu (S of c. 9° N).

**Descriptive notes.** 20.5 cm. Small laughingthrush, dull olive-brown above with white supercilium, grey-streaked whitish breast and rufous-chestnut lower underparts. Nominative race has crown dark brown, upperparts shading from brown-tinged dark olive on nape to ochre-tinged dark olive on rump, with upperwing and tail olive-brown; white supercilium, pale greyish-brown lores and

of nominate race consists of short, mellow, clear, slurred notes, starting with 1–2 steeply ascending, hesitant questioning “quweét” notes, joined in duet by slightly descending series of more abrupt notes “kweer-kweer (kweer, kweer)”; also a more complex “kleer-eeet”, perhaps duetted, the first note strongly downslurred, the second level. Calls include irregularly uttered, very short, subdued, dry, musical, nervous “ptr’tr’tr” or slightly longer “ptr’tr’tr’tr’tr”. Vocalizations of race *meridionalis* apparently unrecorded.

**Habitat.** Thickets lining streams through tea and cardamom plantations, scrub and secondary forest, occasionally gardens, edges of broadleaf evergreen forest, range apparently coinciding with occurrence of wild raspberry (*Rubus*); recorded at 800–2135 m.

**Food and Feeding.** Insects, berries and fruit, including brambles (*Rubus*), *Maesa*, *Luvunga*, and *Trema*. Forages in parties of 6–14 individuals, sometimes up to 30, and may join bird waves. Forages in undergrowth and low bushes, occasionally descending to ground to search among leaf litter.

**Breeding.** Dec–Jun. Nest, built by both sexes, a cup made of coarse grasses, moss and bracken leaves, lined with fine grasses, placed up to 3 m above ground in bush or among tall bracken. Clutch 2 eggs, pale greenish-blue to pale blue, rather thinly marked with spots, small blotches, lines and scrawls of brownish and reddish-purple to bright claret (very similar/identical to those of *S. cassiniana*); incubation by both sexes, nestlings fed by both sexes; no information on duration of incubation and nestling periods.

**Movements.** Resident.

**Status and Conservation.** Not assessed. At best, Near-threatened, as hitherto considered, but re-evaluation required, in light of removal of race *jerdoni* to *S. cassiniana*. Restricted-range species: present in Western Ghats EBA. Although this species’ range is small, its tolerance for disturbed habitats suggests that it is not immediately threatened by habitat modification. Increasing human population, however, has led to increased illegal encroachment into Western Ghat forests, livestock grazing and the harvesting of fuelwood and huge quantities of forest products, such as bamboo and canes. Furthermore, hydropower development and road-building are causing reductions in forest cover in some areas.

**Bibliography.** Ali & Ripley (1972), Bates (1931, 1935), Berlioz (1930), Collar *et al.* (2001), Grimmett *et al.* (1998), Hume & Oates (1889), Rasmussen & Anderton (2005), Stattersfield *et al.* (1998), Stuart Baker (1922).

## 234. Black-chinned Laughingthrush

### *Strophocincla cassiniana*

**French:** Garrulaxe des Nilgiri **German:** Zimtbrusthäherling **Spanish:** Charlatán de los Nilgiris  
**Other common names:** Rufous-breasted Laughingthrush, Nilgiri Laughingthrush (*cassiniana*); Grey-breasted/White-breasted/Jerdon’s Laughingthrush (*jerdoni*)

**Taxonomy.** [*Crateropus*]. *cassiniana* [sic] Jerdon, 1839, Nilgiri Hills, India.

Genus usually subsumed in *Garrulax*. Species sometimes placed in genus *Trochalopteron*. Race *jerdoni* has until recently often been combined in a separate species with *S. fairbanki*; further study required. Two subspecies recognized.

**Subspecies and Distribution.**

*S. c. jerdoni* (Blyth, 1851) – SW Karnataka (Brahmagiri Hills, Banasore Peak) and NE Kerala (Coorg, Wynad), in SW India.

*S. c. cassiniana* (Jerdon, 1839) – Nilgiri Hills (W Tamil Nadu and adjacent NE Kerala).

**Descriptive notes.** 20–5 cm. Small laughingthrush, dull bronzy brown above, dull rufous below, with blackish face and throat and bold white supercilium. Nominative race has crown dark brownish-grey with slight bronzy sheen, shading paler to slightly bronzy grey-brown on neck side and upperparts, less grey lower down, upperwing and tail ochrous-brown; white supercilium, dull rufous ear-coverts; blackish lores, short postocular eyestripe, chin and upper throat, shifting abruptly (but not clear-cut) to rich rufous lower throat to belly, with rich ochrous-brown flanks, thighs and vent; iris crimson or reddish-brown; bill dull

black or horn-brown; legs plumbeous brown. Sexes similar. Juvenile apparently undescribed. Race *jerdoni* differs from nominate in greyer-shaded crown, greyer mantle and back; silvery-grey ear-coverts shading to whitish-grey neck side, lower throat and breast, breast with indistinct greyish (sometimes rufous-tan) streaking. **Voice.** Songs of several types: one a long, rising, crescendoing series of short, worried-sounding, nasal “aingk” notes, perhaps falling away after several seconds, then rising again and ending suddenly; another a comical-sounding, rather cackling, rising, very nasal “onk-ur-whur-whéenk” (first notes hoarse, last 2 whistled and successively longer and stressed), followed by low hoarse laughing “urg-urg-urg...”; third a curious, halting, very nasal “whur-wháink, whur-wháink”, which may be followed by rising, rapid sequence of very nasal “aingk” notes. Song also said to be a rather nasal “u wi-yu, wi-yu wi”, accompanied antiphonally (perhaps from females) by low “dhu-dhu-dhu”. Calls include irregularly repeated, short, gravelly, nasal, staccato, grunting “grnk” or “grmnk”, a more rattled version, and rapid nasal, hard, chattering “chink-chink-chink...”. Also, harsh “jho” notes mixed with high-pitched “pititit” notes.

**Habitat.** Broadleaf evergreen and semi-evergreen forest, especially “shola” forest (formations in ravines or upland depressions) with dense undergrowth and fringes; also forest edge, wooded gardens, patches of thick scrub (including *Lantana camara*, and “hill guava” *Rhodomyrtus tomentosa*); only occasionally to rarely in eucalypts (*Eucalyptus*), acacia (*Acacia*) and tea plantations. At 1220–2285 m.

**Food and Feeding.** Invertebrates; also nectar, flowers, fruits and berries, including those of brambles (*Rubus*) and *Rhodomyrtus tomentosa* and introduced Peruvian cherry or cape gooseberry (*Physalis peruviana*). Forages on ground and among low vegetation, in pairs or in flocks of twelve or more individuals, sometimes in association with other species in bird waves.

**Breeding.** Jan–Jul. Nest a bulky but compact, sometimes externally untidy, usually deep cup, made of roots, dead leaves, leaf skeletons, small twigs, coarse grasses, moss, lichen, withered fibrous coverings of *Physalis peruviana* and cobwebs, lined with fine grasses, plant fibres, moss roots, fur, feathers and “cotton-wool”, placed on ground or up to 4 m above ground in bush or small tree, often in relatively open area of forest edge; in one study of 39 nests, 28 were in indigenous and nine in exotic plants, most being built near stream, road or cattle trail, and most in outer branches of tree. Clutch 2–3 eggs, pale blue to greenish-blue, with blotches, streaks and specks of pale reddish-brown, ash, purplish-brown or blackish-brown; incubation and nestling periods each 16 days. Commonly parasitized by Jacobin Cuckoo (*Clamator jacobinus*), which lays up to two eggs per nest. Rates of nest predation fairly high; in one study of 39 nests, 72 eggs laid, 52 hatched and 40 nestlings successfully fledged, giving success of 57%; success 60% in another study.

**Movements.** Resident.

**Status and Conservation.** ENDANGERED (nominative race only; taxonomic rearrangement, with *jerdoni* now included in present species, necessitates new assessment, which would probably reduce threat status to Vulnerable). Restricted-range species: present in Western Ghats EBA. Population of nominate race estimated at 2500–9999 individuals and decreasing, within geographical range of 1620 km<sup>2</sup>; generally common or abundant within this range at start of 20th century, and recent observations indicate it to be only locally common. Large-scale conversion of habitat to plantations, reservoirs and crops and human settlement pose main threats. Commercial plantations of tea, eucalypts and acacias have been increasing in size across range. Between 1961 and 1988, 47% of evergreen/semi-evergreen forest was lost in Kerala portion of Western Ghats, with increases in plantation and deciduous forest cover of 6% and 7.5%, respectively. Nominative race occurs in Mukurti National Park, in Tamil Nadu, and small part of range encompassed by upper reaches of Silent Valley National Park, in Kerala. Some sholas in Nilgiri Hills afforded partial protection as reserve forests and included in Nilgiri Biosphere Reserve, but these receive considerably less protection than do national parks. Race *jerdoni* fairly common locally.

**Bibliography.** Ali & Ripley (1972), Anon. (2006d), Bates (1931), Berlioz (1930), Betham (1902), Butchart & Stattersfield (2004), Collar *et al.* (2001), Davison (1883), Grimmett *et al.* (1998), Hume & Oates (1889), Islam (1987, 1989, 1990, 1994, 1995), Khan (1978), Rane (1982), Rasmussen & Anderton (2005), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stuart Baker (1922), Zacharias & Gaston (1993).

## 235. Bhutan Laughingthrush

### *Strophocincla imbricata*

**French:** Garrulaxe du Bhoutan

**German:** Braunnäherling

**Spanish:** Charlatán de Bután

**Taxonomy.** *Garrulax*]. *imbricata* Blyth, 1843, Bhutan.

Genus usually subsumed in *Garrulax*. Species sometimes placed in genus *Trochalopteron*. Until recently considered conspecific with *S. lineata*, but distinct in many features, with no intergradation despite close geographical proximity; also, most vocalizations differ considerably, and playback of recordings has apparently elicited no response. Monotypic.

**Distribution.** Bhutan, NE India (W Arunachal Pradesh) and adjacent S China (S & SE Xizang).

**Descriptive notes.** 19–20 cm; 40–55 g. Small laughingthrush, streaky warm brown with grey ear-coverts. Has crown to mantle and back warm mid-brown with long glossy shafts, these becoming white on back but all fading to plain dirty greyish-brown on rump and uppertail-coverts; wing fringes warm mid-brown, fringes pale grey on outermost primaries and pale olive on adjacent ones, tail dull rufescent brown with narrow dull buffy-white tips; face (lores, submoustachial area, cheek, ear-coverts and superciliary area) and neck side pale greyish-brown with narrow white shaft streaks; chin to belly slightly pinkish-tinged greyish-brown

with whitish shafts, shading to plainer, darker, dirtier rufous-brown on flanks, thighs and vent; iris bright reddish-brown to brown; upper mandible dark horn, lower mandible pale horn; legs horn-brown to brownish-black. Distinguished from very similar *S. lineata* by unstreaked rich brown crown, lack of rusty ear-coverts, more extensive white shaft streaks from moustachial region and ear-coverts to side of neck, richer brown upperparts and tail, absence of rufous wingpanel and of background grey in plumage above or below (making for a richer, darker lower belly), considerably longer tail with greatly reduced pale tips. Sexes similar. Juvenile apparently undescribed. **Voice.** Songs recall those of *S. lineata* but shorter, with introductory notes greatly reduced and jumbled (probably often inaudible): “(fz)-ééyééw” (main strophe strongly downslurred), “(fwer)fwééyééw” (almost inaudible introductory notes, then quickly upslurred and downslurred thin whistle), and “(fst)-kléééééé” (prolonged end note); also a quick, uninitiated 3-note “kip-ká-wéér”, which may be duetted with chittery-prefaced songs more like those of *S. lineata*, or similar version prefaced by buzzy, excited, squealing “schléé”. First song type sometimes duetted with more slurred “tuuwhéééééé”. Songs may also be mixed with buzzy chittering and trills in continuous sequence or burry triplets (which are also sometimes given alone), which have each note descending (but all on same pitch), the first the longest but the other two louder. Calls include short, buzzy, excited upturned “bzrrt-bzrrt...”, irregularly repeated.

**Habitat.** Bushes and long grass, thick scrub bordering cultivation, scrub and thickets in open and secondary forest, including in areas opened up by tree-felling; found at 1400–2400 m, but occasionally down to 900 m and up to 2900 m, and one record in W Bhutan at 3800 m.

**Food and Feeding.** No information on diet; presumably small invertebrates and some vegetable matter. Occurs in pairs or in small flocks of up to six individuals, and of 10–20 or more birds during winter. Forages primarily on ground, generally rather confiding.

**Breeding.** Apr–Jun. Nest-building pair in Bhutan (in Apr), disappearing into bracken thicket. No other information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Common in Bhutan: near Zhemgang, density of 0.8 breeding pairs/km of road at 1600–1900 m (probably in suboptimal habitat). Present in and/or near Eaglenest Wildlife Sanctuary (Arunachal Pradesh), in India.

**Bibliography.** Ali *et al.* (1996), Chatterjee & Saxena (1996), Collar *et al.* (1998), Grimmett *et al.* (1998), Jullien & Kinnear (1937, 1944), Meyer de Schauensee (1984), Rasmussen & Anderton (2005), Singh (1995), Spierenburg (2005), Vaurie (1954b), Zheng Zuoxin *et al.* (1983).

## 236. Streaked Laughingthrush

### *Strophocincla lineata*

**French:** Garrulaxe barré **German:** Borstenhäherling **Spanish:** Charlatán Barrado  
**Other common names:** Himalayan Laughingthrush

**Taxonomy.** *Cinclosoma lineatum* Vigors, 1831, Simla–Almora district, north-west Himalayas, India. Genus usually subsumed in *Garrulax*. Species sometimes placed in genus *Trochalopteron*. Until recently considered conspecific with *S. imbricata*, but distinct in many features, with no intergradation despite close geographical proximity; also, most vocalizations differ considerably. Five subspecies recognized.

#### Subspecies and Distribution.

*S. l. schachdarensis* Stepanyan, 1998 – SE Uzbekistan E to SE Tajikistan.  
*S. l. bilkevitchi* (Zarudny, 1910) – SW Tajikistan and adjacent SE Uzbekistan, NE & SE Afghanistan and W Pakistan.  
*S. l. gilgit* (E. J. O. Hartert, 1909) – N Pakistan (Chitral E to Hunza, Skardu and Astor, N of Burzil Pass) and adjacent N part of E Afghanistan.  
*S. l. lineata* (Vigors, 1831) – NE Pakistan (S of R Indus) E to N India (Uttaranchal Pradesh).  
*S. l. setafer* (Hodgson, 1836) – Nepal E to Sikkim and N West Bengal (India), and adjacent S China (S Xizang).

**Descriptive notes.** 18–20 cm; 35–46 g. Small laughingthrush, streaky-brown and grey with dull rufous ear-coverts. Nominant race has crown, neck side and mantle streaked dull rufous-brown and grey (grey dominant), shifting on scapulars and back to dull rufous-brown with sparse long whitish shaft streaks, rump dull pale olive-grey; upperwing and tail rufescent pale grey-brown, former with strong rufescent wingpanel, latter with dark-bordered dirty greyish tips; ear-coverts dull rufous, face (lores, supercilium, cheek and submoustachial area) streaked dull rufous and grey (grey subordinate); chin to lower underparts similar with

narrow buff shaft streaks, flanks, thighs and vent dark ochraceous olive-brown; iris reddish-brown to brown; bill dark brown, paler below; legs flesh-brown or pale horn-brown. Sexes similar. Juvenile is somewhat warmer and less distinctly streaked than adult, crown showing vague dark striations, mantle and breast with thin pale shaft streaks. Race *setafer* is like nominate but centres of streaks on crown and mantle blacker, posterior upperparts darker olive, base colour of underparts warmer and browner, and broader blackish subterminal tailband; *bilkevitchi* is much paler and greyer above than nominate, grey rump and uppertail-coverts, grey (rather than grey-brown) belly, paler, buffier underpart markings, paler rusty ear-coverts; *gilgit* is similar to previous but somewhat colder, darker grey; *schachdarensis* is palest. Voice. Apparent songs of 2–3 types. First (perhaps from male) a very thin, high-pitched whistle followed by clear note, “siiii-chu...siiii-chu...” or “siiii-siiii-chu”; second (perhaps from female) a fast, liquid, tinkling trill ending with clear note, “trrrrititit-chu”, also described as loud chattering notes immediately followed by clear, thin, elastic whistle (falling steeply and ending at low pitch), e.g. “chichichichi-chéwéw”, or similar with additional air, rising and then falling note (e.g. “chittitititichééter-whéééé!”), chittery notes fairly evenly spaced, and often ascending and crescendoing. Both types of song may be given on own or antiphonally, and are repeated every few seconds. Often given in duet with song is a loud, steeply falling, sibilant “pseeuu, pseeu-pseeu” (last note shortest, clearest); variants may be mixed with single higher, shorter falling note followed by 3 short, thin, wheezy, progressively shorter notes on same pitch, e.g. “seer-pseep-seep-sip”. Third song type short, syncopated, apparently different from first type above, comprises mostly dry, burry trills, e.g. “(ka-)krrrcheequerrrrr” (last note prolonged, strongly descending and diminishing), often in duet with loud, steeply falling, sibilant “pseeuu, pseeu-pseeu”, last note shortest and clearest. Calls include low, harsh grumbling, mixed with short high-pitched notes; very high-pitched, buzzy short notes continuously in alarm, “tsip, tsip, tsip, tsip...”.

**Habitat.** Bushes and scrub, including brambles (*Rubus*), the witch-hazel *Parrotiopsis jaquemontiana* (Hamamelidaceae), Lindley’s spiraea (*Spiraea lindleyana*), hopseed bush (*Dodonaea viscosa*) and dwarf willow (*Salix*), on hill slopes and ravine slopes; also barberry (*Berberis*) and rose (*Rosa*) shrubbery, scrub and bushes in open forest, at forest edge, and around human habitation, field borders, gardens, thick scrub and stone walls near cultivation; also juniper forest and chilgoza pine (*Pinus gerardiana*) scrub-forest in Baluchistan (Pakistan). Found at 1400–3905 m (mostly 1800–3000 m), some descending as low as 600 m during harsh winter weather.

**Food and Feeding.** Insects, including moths and caterpillars (Lepidoptera), small flies (Diptera), and ants (Formicidae); also spiders (Araneae), and berries, fruits and seeds; occasionally breadcrumbs. Found in pairs or in small parties of 3–6 individuals, depending on season. Keeps to ground. A “garden bird” in W Himalayan towns and villages, feeding in open, as well as under bushes.

**Breeding.** Mar–Oct; multi-brooded. Nest reportedly an outwardly loose, untidy, thick-walled, deep cup (sometimes rather massive), made of coarse dry grasses, fine plant stems, dead leaves, fibrous plant bark, creepers, dry twigs, ferns and moss, lined with fine grass roots, fine grasses, rootlets, pine needles and hair, placed in thick bush, on low tree branch, in pollard tree, thick grass or on bank among overhanging grass, rarely in honeysuckle on house verandah, from ground level to 2–4 m up. Clutch 2–4 eggs, usually 3, pale greenish-blue to pure pale blue; incubation by both sexes; no information on duration of incubation and nestling periods. Nests apparently often parasitized by Jacobin Cuckoo (*Clamator jacobinus*), Large Hawk-cuckoo (*Cuculus sparveriioides*) and Indian Cuckoo (*Cuculus microgaster*).

**Movements.** Resident; some minor altitudinal movements associated with hard winter weather.  
**Status and Conservation.** Not globally threatened. Generally the commonest and most conspicuous laughingthrush in W Himalayas. Widespread and common in Pakistan, including in Palas Valley, in North-West Frontier Province. Locally common in Shey-Phoksundo National Park, in Nepal. In India, common in Nanda Devi Biosphere Reserve (Uttaranchal), common (mainly in terraced fields) in Mahatma Harsang Wildlife Sanctuary (Himachal Pradesh), and present in Buxa Tiger Reserve (West Bengal). Common in small range in China.

**Bibliography.** Ali & Ripley (1972), Allen *et al.* (1997), Bates & Lovther (1952), Berlioz (1930), Cheng Tsohsin (1987), Choudhury (2003), Collar (2006), Gaston *et al.* (1994), Grimmett & Robson (1986), Grimmett *et al.* (1998), Hume & Oates (1889), Inskipp & Inskipp (1991, 1993b), Inskipp *et al.* (2000), Islam (1993), Leonovich (1962), Martens & Eck (1995), Meyer de Schauensee (1984), Mishra (1997), Priemé & Øksnebjerg (1994), Raja *et al.* (1995), Rasmussen & Anderson (2005), Rasmussen (1992), Rasmussen (2004), Tattersall (1983), Ziswiler (1954), Ziswiler (1972), Zheng Zuoxin *et al.* (1983).

## 237. Striped Laughingthrush

### *Strophocincla virgata*

**French:** Garrulaxe flammé **German:** Strichelhäherling **Spanish:** Charlatán Rayado  
**Other common names:** Manipur (Streaked) Laughingthrush

**Taxonomy.** *Trochalopteron virgatum* Godwin-Austen, 1874, Razami, Naga Hills, Nagaland, India. Genus usually subsumed in *Garrulax*. Species sometimes placed in genus *Trochalopteron*. Monotypic.

**Distribution.** S Assam (N Cachar), Nagaland, Manipur and Mizoram, in NE India, and adjacent W Myanmar.

**Descriptive notes.** 23 cm. Fairly small, slim laughingthrush, brown with narrow whitish streaks above, with chestnut wings, buffy-white and rufous face, chestnut throat and whitish-streaked rufous-buff belly. Has crown to nape dull chestnut-brown, shading to more olive grey-brown on mantle, back and scapulars, all with long whitish shaft streaks, rump, uppertail-coverts and tail plain olive grey-brown; greater upwing-coverts whitish-tipped rich chestnut, with pale greyish outer primaries and chestnut wingpanel; supercilium from bill base buffy white, turning white posteriorly, lores rufous, upper ear-coverts dull chestnut-brown with

buffy streaks, submoustachial streak, cheek and lower ear-coverts buffy; chin, malar and upper throat rich chestnut, shading to rufous-chestnut and acquiring narrow whitish shaft streaks on lower throat and breast, streaks continuing onto pale rufous-buff belly and fading out on more richly rufescent lower underparts; iris brown to pale brown, sometimes yellowish, orbital skin dusky plumbeous; bill black to blackish-brown; legs flesh to pinkish-grey. Sexes similar. Juvenile is paler, more rufescent above than adult, with paler throat, no streaking on lower underparts. Voice. Song of two types, territorial in function, often given antiphonally by pairs. First type (probably by male) a clear, hurried “chwi-pieu”, “pi-pweu” or “wiwi-wew”, repeated every few seconds, alternatively as thin, sweet, quick, anxious-sounding whistle with short downslurred and then upslurred introductory note, “tui’téééé” (“ééé” strongly downslurred and ending abruptly at low point), or longer version with more and higher-pitched introductory notes. Second type (probably by female) a loud staccato rattling trill, usually with shorter introductory note, “cho-prrrrrr” or “chrrru-prrrrrr”, repeated after slightly longer intervals. Calls with mixed harsh “chit” and “chrrrrr” notes.

**Habitat.** Thick scrub, fern and grass cover near broadleaf evergreen forest, secondary growth, forest edge, abandoned cultivation; at 900–2400 m.

**Food and Feeding.** Mainly insects. Generally found singly or in pairs; not so gregarious as some laughingthrushes. Skulking.

**Breeding.** Apr–Jul. Nest reportedly a deep, rather neat, stoutly built cup, made of tendrils, creeper stems, dead bamboo and other leaves, grasses, roots, fine bents, bracken and moss, lined with fern roots and stalks, moss and grass roots, rootlets, fine grasses and feathery grass-tails, placed from near ground to 2–4 m up in thick bush, small tree or grass. Clutch 2–3 eggs, clear pale blue to pale blue-green. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Eastern Himalayas EBA. In India, locally not uncommon in Assam and common resident in Nagaland in 1990s, although exploited by cagebird trade; seen near Phawngpui (Blue Mountain) and in Murlen National Parks, in Mizoram. Common and evidently distributed throughout the Chin Hills in Myanmar, where fairly common in Natmataung National Park.

**Bibliography.** Ali & Ripley (1972), Berlioz (1930), Choudhury (2000, 2001, 2006), Godwin-Austen (1874), Grimmett *et al.* (1998), Hopwood & Mackenzie (1917), Rasmussen & Anderson (2005), Robson (2000), Robson *et al.* (1998), Smythies (1986), Stattersfield *et al.* (1998), Stresemann & Heinrich (1940a), Stuart Baker (1893), Venning (1912).

## Genus *PTERORHINUS* Swinhoe, 1868

## 238. White-browed Laughingthrush

### *Pterorhinus sannio*

**French:** Garrulaxe à sourcils blancs **German:** Weißwangenhäherling **Spanish:** Charlatán Payaso  
**Other common names:** White-cheeked Laughingthrush(l)

**Taxonomy.** *Garrulax sannio* Swinhoe, 1867, interior of Fujian, China. Genus normally subsumed into *Garrulax*; present species has recently been treated in *Dryonastes*. Four subspecies recognized.

#### Subspecies and Distribution.

*P. s. albosuperciliaris* (Godwin-Austen, 1874) – S Assam (N Cachar), Nagaland and Manipur, in NE India.  
*P. s. comis* (Deignan, 1952) – NE & E Myanmar, NW Thailand, N Laos, NW Vietnam (W Tonkin) and S China (W & C Yunnan).  
*P. s. oblectans* (Deignan, 1952) – SC China (SE Gansu and S Shaanxi S to SW Sichuan and E to W Hubei and N Guizhou).  
*P. s. sannio* (Swinhoe, 1867) – NE Vietnam (E Tonkin), and SE China from E Yunnan and Guizhou (except N) E to NE Jiangxi and Fujian.

**Descriptive notes.** 22–24 cm; 52–83 g. Rather small, dull brown laughingthrush with dark brown crown and area behind eye contrasting with white supercilium looping in front of eye to meet broad buffish-white cheek patch. Nominant race has crown rich dark brown, upperparts dull mid-brown with very vague darker streaks or lines, shading slightly olive lower down and on wing fringes, tail as crown, though sometimes paler, long supercilium, lores, cheek and moustachial area to lower ear-coverts whitish, upper ear-coverts bronzy dark brown, chin to breast warm mid-brown, paler and pinker on neck side and shading to buffish-olive on mid-belly and dull greyish olive-brown on flanks and thighs, vent cinnamon-buff; iris dull brownish-maroon to rufous-chestnut, orbital skin pale flesh-grey; bill blackish or horn-brown; legs grey to flesh-brown. Sexes similar. Juvenile has

harsh buzzy "dzwee" notes when agitated.

**Habitat.** Scrub and grass, secondary growth, bamboo thickets, open hillsides covered with bracken and wild bramble (*Rubus*) patches, open grasslands, cultivation borders. In Sichuan and Yunnan (China) occupies extensively modified habitats, even city parks and gardens, frequenting shrubs and flowerbeds. Found at 75–2600 m, but generally only 600–1830 m in India and SE Asia, though locally as low as 215 m in SE Asia.

**Food and Feeding.** Small molluscs, also grasshoppers and crickets (Orthoptera); also berries, seeds, rice, oats, and other vegetable matter. Forged singly or in pairs; usually in small noisy parties outside breeding season. Forages in undergrowth and on ground, searching through leaf litter. Less shy than most laughingthrushes.

**Breeding.** Mar–Aug; multi-brooded. Nest reportedly a fairly compact, thick-walled cup, made of grass, ferns, roots, bamboo and other leaves, rice and wheat straw, vines, and pine twigs, bound together with weed stems and tendrils, lined with fern roots and stems, tendrils, rootlets, fine grass, conifer twigs and needles, and bamboo leaves (some nests made almost entirely of bamboo leaves and grass), placed 0.6–6 m above ground in thick bush, brambles, mass of overhanging grass, reeds, bamboo, small sapling, tree, occasionally in roof of building. Clutch 3–4 eggs (usually 3 in Myanmar, 4 in China), pale blue or beautiful soft blue-green to delicate greenish-white, or white; incubation by both sexes, period 14–17 days; nestlings fed by both sexes, nestling period 12 days.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Current status in NE India uncertain, with no recent information. Moderately common to very numerous in S China, where recorded in 12 (22%) of 54 surveyed sites (of which 52 are nature reserves); abundant c. 90 years ago in SE Yunnan. Population in Hong Kong (of captive origin) scarce, local and much reduced; decline may reflect occupation of preferred habitats by *Leucodioptron canorum* and *Garrulax perspicillatus*. Generally locally common to common in SE Asian range. Reputed to be a pest in crops and fruit orchards.

**Bibliography.** Ali & Ripley (1972), Anon. (2004c), Berlioz (1930), Bingham (1903), Caldwell & Caldwell (1931), Carey *et al.* (2001), Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paoli (1960, 1962), Cheng Tsohsin *et al.* (1963), Cook (1913), Corlett (1998), Cox *et al.* (1992), David-Beaulieu (1944), Davidson (1998), Deditius (1897), Delacour & Jabouille (1931a), Godwin-Austen (1874), Grimmett *et al.* (1998), Harrington (1914a), Hewson (1983), Huang Qiang, Deng Heli & Mao Ke (1995), Huang Qiang, Huang Yongzhao & Deng Heli (1993), Hume (1888), King (1987, 1989a), Kinnear (1929), La Touche (1923, 1925–1930), Lee Kwok Shing *et al.* (2006), Lekagul & Round (1991), Lewthwaite (1996), Liu Kezhi *et al.* (1994), Meyer de Schauensee (1984), Nguyen Duc Tu *et al.* (2001), Rasmussen & Anderton (2005), Riley (1926), Riley (1952), Robson (2000), Round (1983), Smythies (1986), Stanford & Mayr (1941), Stanford & Ticehurst (1938), Stuart Baker (1893), Tan Yaokuang & Cheng Tsohsin (1964), Tizard *et al.* (1997), Traylor (1967), Vaurie (1954b), Viney *et al.* (1994), Vo Quy (1971), Wang Zhijun & Wei Tianhao (1983), Wickham (1929), Wu Zhikang *et al.* (1986), Yu Zhiwei *et al.* (1986), Zhang Quntan *et al.* (1994), Zhao Xiubi (1994), Zheng Zuoxin & Qian Yanwen (1973).

## 239. Plain Laughingthrush

### *Pterorhinus davidi*

**French:** Garrulaxe de David **German:** Davidhäherling **Spanish:** Charlatán de David  
**Other common names:** (Père) David's Laughingthrush, Peking Laughingthrush, David's Babbler

**Taxonomy.** *Pterorhinus davidi* Swinhoe, 1868, Peking (Beijing), Hebei, China. Genus normally subsumed into *Garrulax*. Several further races proposed, including *funehris* (from NE Qinghai), *exspectatus* (NW Gansu) and *chinganicus* (N Hebei E to NW Manchuria), but differences negligible or undetectable in larger samples. Two subspecies recognized.

**Subspecies and Distribution.**

*P. d. davidi* Swinhoe, 1868 – NC & NS China from NE Qinghai (Qinghai Hu region and Lenglong Ling) E to NE Hebei, extreme SW Liaoning and N Henan (Taihang Shan); also, apparently disjunctly, in NE Nei Mongol.

*P. d. concolor* (Stresemann, 1923) – N Sichuan (Songpan region S to Baoxing) and adjacent E Qinghai (Baima region), in SC China.

**Descriptive notes.** 23–25 cm; 52–69 g. A medium-sized featureless laughingthrush, plain grey-brown with curved yellow bill, grey wingpanel and mostly blackish tail. Nominate race has crown and upperparts uniform brownish mid-grey with faint pinkish-lavender tinge, upperside slightly darker with grey edges of inner primaries, tail as wing basally but becoming blackish on distal third; long narrow bristles overlap nostril, lores and feathers above and below eye mottled blackish and thinly whitish (especially over eye), supercilium from eye to over ear-coverts paler and buffier than upperparts, ear-coverts as upperparts; bristly chin blackish-brown, submoustachial area and upper throat pale brownish-grey with dark brown shaft streaks, underparts pale brownish-grey, slightly darker on flanks and vent; iris greyish-brown to light brown; bill bright yellow, culmen and tip dull yellowish-green; legs dark reddish-grey. Sexes similar. Juvenile is slightly browner than adult. Race *concolor* is slightly greyer and less brown overall than nominate. Voice, Song loud, sweet and warbling, varied and melodious, "wiau wa-wikwikwik woiwoitwoitwoit". Usual call a musical "di dio dio", and for contact and alarm a series of "wiau" notes.

**Habitat.** Scrub-forest, thickets and low bushes, often along streams, willows and bushes along rivers and on hills near rivers, moor-like terrain, mountain slopes, brushwood and scrub oak on dry hillsides; at 1600–3300 m, occasionally down to 800 m.

brown parts noticeably more rufescent, and lacks vague mantle streaks. Race *oblectans* is like nominate, but without shift to buffish-olive on lower upperparts; *comis* has head markings more buffy white; *albosuperciliaris* has crown and upper ear-coverts paler, colder brown. Voice, Harsh, shrill, explosive "tcheu" or "tchow" notes, "tcheu...tcheu...tcheu..."; pair-members may call antiphonally. Alarm call a harsh "tcheurrrr" or "chrrrrrik", sometimes a continuous grumbling "chrrreerraow", interspersed with shrill, sharp "chrrr-ik...chrrr-ik..."; also described as repeated loud, harsh, emphatic, downslurred "jhéw" and "jhéw-jhu";

**Food and Feeding.** Insects, including scaly-winged insects, grubs, also fruit and various seeds, including cultivated millet (*Pennisetum glaucum*); mostly vegetable matter and seeds in winter. Forages in pairs or in small parties of 3–7 individuals.

**Breeding.** Apr–Sept; multi-brooded. Nest an untidy, shallow cup, made of dry grass blades and stems, dead leaves, small twigs and roots, lined with very fine rootlets and fibres or grass stems and feathers, placed in low bush. Clutch 3–6 eggs, plain turquoise-blue. No other information available.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Considered to be relatively uncommon throughout large range.

**Bibliography.** Bangs & Peters (1928), Berlioz (1930), Cheng Tsohsin (1987), Deditius (1897), Hornskov (1991), La Touche (1925–1930), Lönnberg (1924), Meyer de Schauensee (1984), Shaw Tsenhwang (1936), Sien Yaohua *et al.* (1964), Stone (1933), Stresemann (1923c), Vaurie (1954b), Wilder & Hubbard (1938), Yang Guisheng & Xing Lianlian (1995), Zheng Zuoxin & Qian Yanwen (1973).

## Genus *IANTHOCINCLA* Gould, 1835

## 240. Snowy-cheeked Laughingthrush

### *Ianthocincla sukatschewi*

**French:** Garrulaxe de Sukatschew **German:** Kansuhäherling **Spanish:** Charlatán de Sukatschew  
**Other common names:** Sukatschew's Laughingthrush

**Taxonomy.** *Trochalopteron Sukatschewi* Berezowski and Bianchi, 1891, Hsiku and Minchow districts, southern Gansu, China.

Genus traditionally subsumed in *Garrulax*. Monotypic.

**Distribution.** S Gansu and N Sichuan, in C China.

**Descriptive notes.** 27–31 cm. Medium-sized laughingthrush, dull olive-grey above, dull pinkish-brown with rufous-ochre "trousers" below, white cheek outlined in blackish, grey wingpanel, white tips of tertials and tail. Has crown to back and scapulars medium olive-grey with faint pinkish-brown tinge, becoming warmer, tinged ochrous-olive, on lower back, with fluffy pale buffy rump and dull rufous-ochre uppertail-coverts; upperside and tail brownish-grey, fringes of primaries grey and olive and tips of tertials white, central tail feathers olive, next pair grey basally, outer rectrices with white tips; lores and eyestripe

to above rear ear-coverts sooty brown to blackish, topped by pale greyish-brown tinge on forehead and supercilium; cheek and basal ear-coverts white, distal ear-coverts sooty brown and linking with eyestripe and sooty-brown submoustachial stripe; chin to belly pale pinkish-brown, richer behind rear ear-coverts, lower belly, flanks, thighs and vent rufous-ochre; iris reddish-brown; bill dark horn, yellowish-green base; legs pale rose-grey. Sexes similar. Juvenile apparently undescribed. Voice, Song a repeated, shrill "hwii-u, hwii-u" or "h'wi-i, h'wi-i" etc. Also utters grating, scratchy chattering.

**Habitat.** Bushy understorey, scrub and bamboo thickets in coniferous and mixed broadleaf-coniferous forests, dense roadside secondary growth, stunted broadleaf forest at treeline, spruce and willow scrub in river valleys; at 2000–3500 m.

**Food and Feeding.** Insects, seeds and berries; earthworms, strawberries, small red berries and green insect larva seen fed to nestlings. Forages mostly on or close to ground, digging among moss and dry leaf litter, but occasionally ascends trees to c. 3–5 m.

**Breeding.** May–Jun. One nest was a cup of grass and stems, lined with thin twigs, placed 2.5 m above ground in pine tree; five others were 1.2–2.8 m up in branches of spruce tree or willow shrub. Clutch 3 eggs, pale greenish-blue. No other information.

**Movements.** Resident.

**Status and Conservation.** VULNERABLE. Restricted-range species: present in Central Sichuan Mountains EBA. Population estimated at 2500–9999 individuals; geographical range estimated at 29,000 km<sup>2</sup>. Records indicate that this species may occur at moderate densities in suitable habitat, but localized distribution and small number of known localities (eleven; five known to be occupied since 1980) suggest that it could have a small population which is likely to be declining. Main threat likely to be rapid loss and fragmentation of forest since late 1960s through exploitation for timber and clearance for cultivation and pasture; substantial areas of temperate forest must have been lost. Recorded from Jiuzhaigou, Wanglang and Baihe Nature Reserves, in Sichuan, and Lianhuashan Nature Reserve, in Gansu. Several protected areas established for giant panda (*Ailuropoda melanoleuca*) contain habitat suitable for this laughingthrush, but its distribution and abundance in these is poorly known.

**Bibliography.** Anon. (2006d), Bangs & Peters (1928), Berlioz (1930), Bi Zhongli *et al.* (2003), Butcher & Stattersfield (2004), Collar *et al.* (2001), Deditius (1897), Dresser & Delmar-Morgan (1899), Li Guizuan *et al.* (1993), Lönnberg (1924), Meyer de Schauensee (1984), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Zheng Zuoxin *et al.* (1987).

## 241. Moustached Laughingthrush

### *Ianthocincla cineracea*

**French:** Garrulaxe cendré **German:** Grauhäherling **Spanish:** Charlatán Cenicento  
**Other common names:** Ashy/Black-capped Laughingthrush

**Taxonomy.** *Trochalopteron cineraceum* Godwin-Austen, 1874, no locality = Thobal Valley, Manipur, India.

Genus traditionally subsumed in *Garrulax*. Race *cinereiceps* highly distinctive, and possibly a separate species, but intergrades with *strenua* in S China; study needed in order to determine width and length of zone of intergradation, and hence to decide whether or not species status warranted. Individuals of this species in SC & SW Sichuan have not been assigned to race. Three subspecies currently recognized.

**Subspecies and Distribution.**

*I. c. cineracea* (Godwin-Austen, 1874) – NE India (Nagaland, Manipur, Mizoram) and W Myanmar (Chin Hills).

*I. c. strenua* (Deignan, 1957) – NE Myanmar and S China (N & W Yunnan).

*I. c. cinereiceps* (Styan, 1887) – C & E China from S Gansu E to W Shanghai, NW Fujian and N Guangdong, and N & E Sichuan S to S & SE Yunnan and Guizhou; also, apparently disjunctly, in NW & W Shanxi.

**Descriptive notes.** 21–24 cm; 43–55 g. Sandy-brown laughingthrush with black crown, moustache and tail tips and greyish-white head side. Nominative race has black on crown to nape extending in point onto mantle, upperparts buffy grey-brown, becoming slightly paler on rump and uppertail-coverts; upperside with black primary coverts and grey wingpanel, flight-feathers mostly with broad black tips, tertials with black subterminal marks and narrow white tips, tail rufescent grey-brown with broad blackish subterminal and whitish tips; face (lores, broad supercilium, cheek and ear-coverts) grey-tinged buffy-whitish and bisected by

narrow blackish postocular eyestripe; moustachial stripe blackish, submoustachial area pinkish-buff, both breaking into blackish streaks adjoining buffy-white chin and upper throat; lower throat and breast pinkish-buff, belly buff, lower flanks, thighs and vent dull ochre; iris creamy yellow to pink-orange-buff, orbital skin dusky, bill blackish to dull yellowish-brown, paler on lower mandible; legs pale fleshy or greyish-brown. Sexes similar. Juvenile is much more rufescent overall than nominate, lacks head pattern except for postocular stripe. Race *strenua* is like nominate, but has supercilium darker and more buff brown, deeper vinous-pinkish wash on breast; *cinereiceps* has very different head pattern, with dull grey on crown merging into colour of (warmer, darker) upperparts, dull chestnut supercilium and ear-coverts with no postocular streak, dark brown flecking on pale vinous moustachial and submoustachial area, also pale vinous chin to breast. Voice. Song not certainly documented. Calls include brash, rather high-pitched, quickly repeated upslurred short chirrs “pr’r’r’r’ip”, sometimes interspersed with hard chuckling staccato notes.

**Habitat.** Thickets and brambles at edges of broadleaf evergreen forest and mixed broadleaf-coniferous forest, secondary growth, abandoned cultivation, scrub and grass, bamboo, sometimes close to villages; avoids primary forest. At 1280–1830 m in India, 1220–2500 m in Myanmar, 200–1750 m in China, but said to occur at 2135–2745 m in NW Yunnan.

**Food and Feeding.** Small beetles (Coleoptera) and other insects, also seeds, berries and small fruits. Keeps in pairs in breeding season; otherwise in small parties, associating with *Leucodioptron canorum* in S China. Forages mostly on ground. Observed to turn over heaps of buffalo dung in search of food.

**Breeding.** Mar–Oct. Nest reportedly a compact but often flimsy cup, made of moss, leaves, rootlets, grasses and fine twigs, lined with rootlets or fine black and brown stems, tendrils, grasses and moss roots, placed 1–2 m above ground in thick bush or fork of bamboo. Clutch 2–4 eggs (often 2 in Myanmar), blue or plain greenish turquoise-blue; in captivity, incubation by both sexes, period 14 days, chicks left nest at 13–17 days. Brood parasitism by Common Hawk-cuckoo (*Cuculus varius*) reported in India.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Status uncertain in India, with few recent records suggesting scarcity. Uncommon in Myanmar. Fairly common across large range in China, including at Emei Shan Protected Scenic Area, in Sichuan.

**Bibliography.** Ali & Ripley (1972), Bangs (1921), Berlioz (1930), Caldwell & Caldwell (1931), Cheng Tsohsin (1987), Cheng Tsohsin *et al.* (1963), Deditius (1897), Godwin-Austen (1874), Grimmett *et al.* (1998), Hopwood & Mackenzie (1917), Huang Qiang, Deng Heli & Mao Ke (1995), Huang Qiang, Huang Yongzhao & Deng Heli (1993), Kaspar (2005), King (1987, 1989a), King & Zheng Guangmei (1988), La Touche (1899, 1925–1930), Lewthwaite (1996), Liu Kezhi *et al.* (1994), Meyer de Schauensee (1984), Rasmussen & Anderson (2005), Riley (1926), Ripley (1952), Robson (2000), Smythies (1986), Stresemann (1923c), Stresemann & Heinrich (1940a), Stuart Baker (1893), Uchida & Kuroda (1916), Vaurie (1954b, 1959), Wang Zhijun & Wei Tianhao (1983), Wickham (1929), Wu Zhikang, Lin Qiwei *et al.* (1986), Wu Zhikang, Yang Jiongli & Xu Weishu (1981), Yu Zhiwei *et al.* (1986), Zheng Zuoxin & Qian Yanwen (1973).

## 242. Rufous-chinned Laughingthrush

*Ianthocincla rufogularis*

French: Garrulaxe à gorge rousse German: Rostkinnhärherling Spanish: Charlatán Golirrufo

**Taxonomy.** *Ianthocincla rufogularis* Gould, 1835, Sikkim, Himalayas, India.

Genus traditionally subsumed in *Garrulax*. Proposed race *grosvenori* (from W Nepal) synonymized with *grosvenori*. Six subspecies recognized.

**Subspecies and Distribution.**

*I. r. occidentalis* E. J. O. Hartert, 1909 – NE Pakistan (Murree Hills) E in Himalayas to W Nepal.

*I. r. rufogularis* Gould, 1835 – C Nepal F to Bhutan and NE India (C Arunachal Pradesh).

*I. r. rufogularis* Koele, 1952 – Meghalaya, in NE India.

*I. r. rufiberbis* Koele, 1954 – NE India (SE Arunachal Pradesh), N & NE Myanmar and S China (W Yunnan).

*I. r. assamensis* E. J. O. Hartert, 1909 – NE Indian hill states S of R Brahmaputra (except Meghalaya), and NW Myanmar.

*I. r. intensior* (Delacour & Jabouille, 1930) – NW Vietnam (W Tonkin).

**Descriptive notes.** 23–25.5 cm; 58–73 g. Fairly large, dark-faced laughingthrush, olive-brown with black scales above, greyish-white with black spots below, with rufous chin and tail tips. Nominative race has crown black, postocular supercilium, neck side, nape and upperparts warm ochraceous to rufescent olive-brown with black tips (creating effect of stripes, scales), warmer on uppertail-coverts; tail yellowish-brown with broad blackish subterminal band and broad chestnut tips; greater and median uppertail-coverts broadly tipped black, primary coverts blackish, tertials and secondaries as upperparts with broad sub-

terminal black and narrow terminal white tips, primaries sometimes fringed pale grey; loreal area buff (forming buff lateral fan in front of eye), area around eye sooty grey, narrow postocular eyestripe black, ear-coverts blackish-rufous, cheek and broad submoustachial area to behind lower ear-coverts blackish with sparse buff flecks and breaking up into black spots down breast side; chin variably rufous, this colour sometimes extending to upper throat, throat usually whitish, breast and mid-belly pale greyish, variably tinged buffy brown, mid-belly often paler, flanks greyish to warm mid-brown, breast, upper belly and flanks tipped with variably shaped black marks, vent rufous-chestnut; iris dark crimson-brown to purple-red, large orbital ring grey; bill horn-brown, paler on lower mandible; legs greyish-horn to pale horn. Sexes similar. Juvenile has reduced dark markings, particularly on crown and upperparts, with rufous edgings on secondaries and tertials, and more extensive rufous wash below; subadult female said to lack full black cap and to be more rufescent below. Race *occidentalis* is paler above and buffier below than nominate, ear-coverts warmer, rufous on chin paler and more extensive; *rufiberbis* is like previous above, fringes of wingpanel more buffy grey, ear-coverts paler rufous, whole throat and lores pale rufous, submoustachial black reduced and mixed with throat colour, underparts darker and more washed warm buff, black spots reduced; *rufiberbis* is more uniform grey, rufous of chin pale but restricted, upperparts brighter, larger black scaling; *assamensis* has chin and part of ear-coverts pale rust, black on throat side more extensive, upperparts generally more saturated; *intensior* is generally more contrastful, with lores as chin but not fan-like, more broadly blackish around eye, white tips on rear ear-coverts, faint scaling above, uppertail-coverts and tail deeper chestnut, submoustachial area more solidly black, underparts darker and greyer, tail with broader black subterminal band. Voice. Song a repeated loud, measured, clear, slightly husky “whi-whi-whu-whi” or “whi-whi-whi-whi”, with slightly higher penultimate or end note; has been described also as an anxious, strident, clear, highly modulated, whistled “fwhickit! ffwéér, fwer-fwéér” (first note highest, others mellower); or of 2–4 notes with first much burrier than others and last one lowest. Alarm an irregular series of harsh low notes run into short grating rattles; also, a curious low buzzing “jzzzzz”, otherwise described as a strangely jarring, steeply upslurred and then level-pitched twangy “gshwéé!”.

**Habitat.** Rather dense undergrowth in broadleaf evergreen forest (including oak and rhododendron forest), forest edge, secondary growth, scrub (including *Lantana camara*) and dense thickets (including those bordering hill cultivation); favours forest edge and regrowth on abandoned fields in Bhutan, where regularly found in areas with shifting cultivation. At 610–1980 m; locally to 2200 m in Bhutan and Nepal.

**Food and Feeding.** Insects, including wasps (Hymenoptera), also berries and seeds. Found in pairs or in small (family) parties. Forages mostly on ground and among low bushes.

**Breeding.** Apr–Sept in India and Bhutan; multi-brooded. Nest reportedly a fairly deep cup, made of creeper tendrils (these seem to be important), twigs, roots, scraps of bracken, sometimes dead leaves and grasses, lined with rootlets, fine black lichen fibres, black moss roots and scraps of dead leaves, placed 0.6–6 m above ground, usually in fork, in bush or tree. Clutch 2–4 eggs (usually 3 in India), pure white; incubation by both sexes, no information on duration; nestling period in captivity c. 12 days. Brood parasitism by Chestnut-winged Cuckoo (*Clamator coromandus*) and Large Hawk-cuckoo (*Cuculus sparverioideus*) reported.

**Movements.** Resident. In Bhutan, all records below 1000 m are during winter, suggesting some altitudinal dispersal, but this doubtful in view of relatively low elevational range of species.

**Status and Conservation.** Not globally threatened. Presumed extinct in Pakistan; no records since 19th century (1873). Local and frequent in Nepal. In Bhutan status somewhat difficult to assess, as species is less gregarious than most laughingthrushes and easily overlooked by observers; near Zhemgang, density of 1 territory/km of road at 1600–1900 m. Uncommon in India, where rare on New Forest campus at Dehra Dun and uncommon in Dehra Dun valley (Uttaranchal); present in Buxa Tiger Reserve (West Bengal). Generally uncommon in SE Asian range. Scarce in Fan Si Pan National Park, in Vietnam, with no recent records.

**Bibliography.** Ali & Ripley (1972), Ali *et al.* (1996), Allen *et al.* (1997), Berlioz (1930), Delacour & Jabouille (1930, 1931a), Dymond & Thompson (2000), Gaston (1989), Grimmett *et al.* (1998), Harrison (1962), Hume & Oates (1889), Inskipp & Inskipp (1991), Inskipp *et al.* (2000), King *et al.* (2001), Koele (1954), Ludlow & Kinnear (1937, 1944), Mayr (1938), Mohan (1997), Rasmussen & Anderson (2005), Ripley (1952, 1961), Roberts (1992), Robson (2000), Simmons (1962), Singh, A.P. (2000), Singh, P. (1995), Smythies (1986), Spierenburg (2005), Stanford (1941), Stanford & Mayr (1941), Stanford & Ticehurst (1935, 1938), Stevens (1923), Stuart Baker (1893), Ward (1975).

## 243. Chestnut-eared Laughingthrush

*Ianthocincla konkakinhensis*

French: Garrulaxe du Kon Ka Kinh Spanish: Charlatán Orejicastaño  
German: Kastanienohrhärherling

**Taxonomy.** *Garrulax konkakinhensis* J. C. Eames and C. Eames, 2001, Mount Kon Ka Kinh (14° 19' N, 108° 24' E), Gia Lai province, Vietnam.

Genus traditionally subsumed in *Garrulax*. Monotypic.

**Distribution.** C highlands of Vietnam, and adjacent S Laos.

**Descriptive notes.** 24 cm. Forehead, crown and nape are grey with broad black tips, becoming mostly black on hindcrown and nape; mantle and upperside-coverts olive-buff, becoming warmer on scapulars to rump but all with heavy black scaling, uppertail-coverts rufous-brown, tail yellow-tinged rufous-brown with broad black subterminal band and white tips; primary coverts blackish, outer primaries fringed bluish-white, grading to olive-brown on inner primaries, and secondaries and tertials very broadly tipped black with pronounced white terminal fringes; lores and cheek buff, postocular supercilium grey, ear-coverts rufous-chestnut, black submoustachial stripe merging with black on throat side; chin and throat off-white, faintly buff-tinged and with irregular faint blackish conical or anchor-shaped marks that extend more heavily onto olive-buff neck side and breast side, mid-breast grey-washed buff, belly and flanks pale buffy rufous with vague sparse black bars, becoming paler and more rufescent on vent, iris brown to dark brown, upper mandible dark horn, lower mandible pale horn; legs flesh-horn. Distinguished from *I. rufogularis* by having all tail feathers tipped white, bluish-grey remiges with no black band, black-streaked grey forecrown and grey supercilium, and rich buff lower belly and vent, also all-chestnut ear-coverts, off-white throat, and extensive black tips on scapulars and tertials. Sexes similar. Juvenile has only little grey on rear supercilium. Voice. Song a sweet *Turdus*-like rambling series of fairly well-spaced and stressed notes, and some mimicry.

lasting c. 4–6 seconds; very different from that of *I. rufogularis*. Calls include low grumbling “rrreek, rrreek, rrreek...”.

**Habitat.** Broadleaf forest (including the bamboos *Arundinaria* and *Schizostachyum*), forest edge, secondary growth; recorded at 1350–1750 m.

**Food and Feeding.** Presumably invertebrates and some vegetable matter. Occurs singly, in pairs or in small (perhaps family) groups. Forages in understorey. Can be very skulking.

**Breeding.** Mar–Apr. No other information.

**Movements.** Resident.

**Status and Conservation.** VULNERABLE. The species occurs in three protected areas: Dong Ampham National Biodiversity Conservation Area, in Laos, and Ngoc Linh and Kon Ka Kinh Nature Reserves, in Vietnam. Its occurrence in logged forest and secondary habitats suggests that, unlike *I. rufogularis*, it is not a species requiring closed primary forest.

**Bibliography.** Anon. (2006d), Butchart & Stattersfield (2004), Collar *et al.* (2001), Eames & Eames (2001).

## 244. Barred Laughingthrush

### *Ianthocincla lunulata*

**French:** Garrulaxe à lunules **German:** Wellenhäherling **Spanish:** Charlatán Lunado  
**Other common names:** Bar-backed Laughingthrush

**Taxonomy.** *Ianthocincla lunulata* J. Verreaux, 1870, “les montagnes du Thibet chinois” = western Sichuan, China.

Genus traditionally subsumed in *Garrulax*. Forms a superspecies with *S. bieti*, and has been treated as conspecific. Two subspecies recognized.

**Subspecies and Distribution.**

*I. l. lunulata* J. Verreaux, 1870 – S Gansu, S Shaanxi, WC, N & NE Sichuan and W Hubei, in EC China.

*I. l. liangshanensis* (Li Guiyuan *et al.*, 1979) – SC Sichuan, in SC China.

**Descriptive notes.** 24–25 cm; 82 g. Medium-sized, soft-coloured laughingthrush, barred black and buff above, scaled white below, with tail tipped black and white. Nominant race has crown and nape grey-tinged milky brown, upperparts buffy brown with equally broad buff and blackish bars, primary coverts blackish-brown with white tips, pale grey wingpanel; central tail dirty buff-brown with blackish subterminal band and small white tip, outer feathers with stronger black and white tips and some adjacent grey; lores and area around eye whitish, this extending as short broad wedge behind eye (combination of whitish supercilium and upper ear-coverts), lower ear-coverts pale silky buff-brown; submoustachial stripe slightly darker than crown, but merging to pinky-greyish-tinged milky brown of throat and breast, breaking up through short white bars on breast to whitish belly; lower flanks and undertail-coverts generally warm buff with scattered dark bars; iris yellowish-white to white; bill greenish-yellow; legs flesh-coloured. Sexes similar. Juvenile apparently undescribed. Race *liangshanensis* has forehead, crown and nape blackish-brown, head side and chin to upper breast pale blackish-brown, neck side and lower breast also darker. **Voice.** Song a loud, clear and rather fluty “chu-wi”u-wu-whu”u”, repeated every 3–7 seconds; second bird, presumably female, adds quavering “tchrr-tchrr-tchrr-tchrr”. Song transcribed also as “wi-chu...wi-chu-chewee-chu”, with stressed “wi” notes.

**Habitat.** More open broadleaf and mixed broadleaf–coniferous forests, secondary forest, bamboo thickets, at 1200–3080 m, occasionally to 3660 m.

**Food and Feeding.** Presumably invertebrates and some vegetable matter; moths (Lepidoptera) reported. Rather quiet and unobtrusive, feeding mostly on ground.

**Breeding.** Jun. No other information.

**Movements.** Resident.

**Status and Distribution.** Not globally threatened. Formerly considered Near-threatened. Restricted-range species: present in Central Sichuan Mountains EBA. Relatively uncommon.

**Bibliography.** Anon. (2004c), Bangs (1932), Berlioz (1930), Deditius (1897), Li Guiyuan, Liu Liangxi *et al.* (1976), Li Guiyuan, Zhang Qingmao, Luo Jiaze *et al.* (1994), Li Guiyuan, Zhang Qingmao & Zhang Ruiyun (1979), Liu Rusun *et al.* (1998), Meyer de Schauensee (1984), Stattersfield *et al.* (1998), Yu Zhiwei *et al.* (1986), Zhang Quntan *et al.* (1994), Zheng Zuoxin & Qian Yanwen (1973).

## 245. White-speckled Laughingthrush

### *Ianthocincla bieti*

**French:** Garrulaxe de Biet **German:** Perlenhäherling **Spanish:** Charlatán de Biet  
**Other common names:** Biet’s Laughingthrush

**Taxonomy.** *Ianthocincla Bieti* Oustalet, 1897, Tzoku, north-western Yunnan, China.

Genus traditionally subsumed in *Garrulax*. Forms a superspecies with *I. lunulata*, and has been treated as conspecific. Monotypic.

**Distribution.** NW Yunnan and SW Sichuan, in S China.

**Descriptive notes.** 25.5 cm. Medium-sized, white-spotted yellowish-brown laughingthrush. Has crown to nape rich, dull rufescent mid-brown, tinged olive, upperparts similar but more ochraceous and each feather tip with prominent black band and white spot; tail ochraceous mid-brown with broad blackish-brown subterminal band and white tips; upperwing ochraceous mid-brown with dark and white tips and narrow grey wingpanel; primary coverts blackish-brown with dark and white tips; lores, area around eye, postocular eyestripe and rear ear-coverts whitish, rest of ear-coverts brown. Crown, chin, throat and

submoustachial area blackish-brown, upper breast similar with some yellowish-brown and increasingly large white crescents so that belly whitish; flanks yellowish-brown with dark-edged white

spots, thighs and vent dull yellowish-brown; iris pale yellow; bill dark horn-brown, paler tip and lower mandible; legs dull brown. Sexes similar. Juvenile apparently undescribed. **Voice.** Song a loud, clear, descending “wi, wi-wi-wuu”, less descending “wi, ch’wi, wi ch’wu” and “wi, chiu-wu, wu-wu-wi” (rises towards end); in all cases, “wi” notes are louder and rising, and phrases are repeated 2–3 times.

**Habitat.** Recorded mainly in upper temperate and subalpine zones, in variety of forest habitats including bamboo and thickets in more open mixed coniferous–broadleaf forest, spruce–fir (*Picea–Abies*) and fir–rhododendron forest, at 2500–4270 m.

**Food and Feeding.** Invertebrates and fruit. No documented information on behaviour and habits; probably like those of *I. lunulata*.

**Breeding.** Undocumented.

**Movements.** Resident.

**Status and Conservation.** VULNERABLE. Restricted-range species: present in Yunnan Mountains EBA. Population and range poorly known; former estimated at 2500–10,000 individuals and decreasing, latter estimated at 23,400 km<sup>2</sup>. Can occur at fairly high densities in suitable habitat, but paucity of records suggests a fragmented range and small population, both probably declining of twelve known localities for this species, only two (Ma Huang, in Sichuan; Lijiang–Jadu, in Yunnan) known to hold individuals since 1980. Main threat probably loss and fragmentation of forest. Logging in Yunnan caused decline of forest cover from c. 55% of land area in early 1950s to c. 30% in 1975. Similar rapid forest-cover declines in Sichuan since late 1960s driven by logging for timber and conversion to agriculture and pasture. Substantial areas of forest in upper temperate and subalpine zones must have been lost. Virtually all forest at Kianwu Liangshi, where species present in 1989, has been logged. This species is not recorded in any protected areas, but several reserves in Yunnan probably contain suitable habitat; these include Baima Xue Shan National Nature Reserve, Haba Xue Shan, and Bitahai and Yulong Xue Shan Nature Reserves.

**Bibliography.** Anon. (2006d), Berlioz (1930), Butchart & Stattersfield (2004), Collar *et al.* (2001), King (1989c), Meyer de Schauensee (1984), Riley (1926), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

## 246. Giant Laughingthrush

### *Ianthocincla maxima*

**French:** Garrulaxe géant **German:** Riesenhäherling **Spanish:** Charlatán Gigante

**Taxonomy.** *Pterorhinus maximus* J. Verreaux, 1870, “les montagnes du Thibet chinois” = Muping (Paohing), south-east Xizang, China.

Genus traditionally subsumed in *Garrulax*. Has been treated as conspecific with *I. ocellata*, and the two appear to intergrade between upper R Subansiri (India) and Tsangpo Valley, in SE Xizang (China). Monotypic.

**Distribution.** S Gansu and SE Qinghai S to SE & E Xizang and N Yunnan, in SC China.

**Descriptive notes.** 30.5–35.5 cm; 105–136 g. Very large dark-capped, chestnut-faced laughingthrush with white spotting above, buffy tan below. Crown and nape are blackish-brown, sharply changing to pale greyish buffy-brown on mantle and neck side, feathers with broad blackish subterminal bars and dot-like buffish-white tips, shading to rich dark chestnut on back, scapulars, rump and upper-tail-coverts, these patterned as mantle but with terminal dots mostly white; blackish upperwing-coverts tipped white, narrow grey wingpanel; tail blackish-chestnut with black subterminal bar and white tips; lores dirty

whitish to greyish, shading to rufous-buff supercilium, narrow postocular eyestripe blackish, ear-coverts to chin and throat chestnut-rufous, greyer and mottled around gape, upper breast chestnut-rufous with narrow buff and black scaling, becoming buff on mid-breast and shading to buffy tan on remaining underparts; iris pale grey to yellowish; bill horn-brown, lower mandible paler; legs brownish-flesh to yellowish-grey. Sexes similar in plumage, female slightly smaller than male. Juvenile has fewer, more triangular spots on back, unspotted rump and upper-tail-coverts, unbarred duller rufous on throat and breast, shorter tail. **Voice.** Song a repetition (with slight variations) of a loud, clear, sweet, quite rich and melodious, almost *Turdus*-like phrase, “chwi-chui-chwee-chwi”, with very short pauses, e.g. “chwi-chwi-chwi-chwi-wuu, wi-wiu-wi-wu”, “wuu-wuu, wiu-wuu...wi-wiu-wi-wiu-wiu” or “wi-wiu-wi-wi, chu-chui-chu-chui-chu-chui”; described also as loud rambling “tuhheet, tuhheet, fuoo, fweeo-fweo-fweo-fweeo”, a brief “fuiwit, fuiwit, fuiwéé”, and rhythmically repeated “fuiwit-fuiwit-fuiwéé-fuiwéé-fuiwit-fuiwit-fuiwéé-fuiwéé...”, and so on. Very like that of *I. ocellata*, but notes shorter, more modulated, and tempo faster.

**Habitat.** More open broadleaf and mixed broadleaf–coniferous forests, bamboo scrub in broadleaf evergreen forest, prickly oak (*Quercus*) forest with scattered conifers, relatively open broadleaf evergreen forest with willow-like understorey; at 2135–4115 m.

**Food and Feeding.** No information on diet; presumably invertebrates and some vegetable matter. Secretive. Often associates with other laughingthrushes. Forages mostly on ground, occasionally ascending trees to 5 m.

**Breeding.** May–Aug. Nest a shallow cup of small twigs, lined with dry grass, placed 1–2 m above ground in bamboo clump. Clutch 2 eggs, blue. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Locally common.

**Bibliography.** Ali & Ripley (1972), Bangs & Peters (1928), Berlioz (1930), Cheng Foshin (1987), Deditius (1897), Dowell *et al.* (1997), Eck (1987), King (1989c), King & Peng Jitai (1991), Lee Ichhow *et al.* (1965), Lönngberg (1924), Ludlow (1951), McCarthy (2006), Meyer de Schauensee (1984), Rasmussen & Anderton (2005), Riley (1926), Robson (1986), Schäfer & Meyer de Schauensee (1938), Sien Yachua *et al.* (1964), Stresemann (1923c), Ye Xiaodi & Wang Zuxiang (1993).

## 247. Spotted Laughingthrush

### *Ianthocincla ocellata*

**French:** Garrulaxe ocellé **German:** Waldhäherling **Spanish:** Charlatán Ocelado  
**Other common names:** Ocellated/White/White-spotted Laughingthrush

**Taxonomy.** *Cinclosoma ocellatum* Vigors, 1831, Himalayas = Darjeeling, West Bengal, India.

Genus traditionally subsumed in *Garrulax*. Has been treated as conspecific with *I. maxima*, and the two appear to intergrade between upper R Subansiri (India) and Tsangpo Valley, in SE Xizang

(China). Race *maculipectus* previously listed using older name *similis*; with inclusion of present species and *Trimalopis variegatus* *similis* in genus *Garrulus*, name *similis* became preoccupied, and was replaced by *maculipectus*; this made the name *similis* permanently invalid for the latter now known as *maculipectus*, even though herein the two forms are not treated as congeners. *Leucophaea rufescens*.

#### Subspecies and Distribution

*I. o. griseicauda* (Koele, 1950) – N India (Uttaranchal Pradesh) and W Nepal.

*I. o. ocellata* (Vigors, 1831) – C Nepal E to Bhutan, NE India (W Arunachal Pradesh) and adjacent S China (S & SE Xizang).

*I. o. maculipectus* Hachisuka, 1953 – N Myanmar and S China (W & NW Yunnan).

*I. o. artemisiae* (David, 1871) – EC China (S Gansu S to WC Sichuan and extreme NE Yunnan; W Hubei).

**Descriptive notes.** 30–33 cm; 104–136 g. Very large dark-capped laughingthrush with scaly pattern. Nominative race has crown to nape matt-black, neck side, mantle, back and scapulars greyish-buff with broad black subterminal bars and whitish terminal tips (giving black-and-white spotted effect), posterior upperparts and upperwing-coverts dull rufous-chestnut with same spotting effect; tertials dull rufous-chestnut with blackish-edged white tips, flight-feathers edged pale grey (pale wingpanel); central tail feathers dull rufous-chestnut with black tips, outer tail feathers dull rufous-chestnut basally, dull pale grey on mid-length, black-

ish subterminally and with broad white tips; lores, base of submoustachial area and broad supercilium pale rusty-rufous, ear-coverts, cheek and lower submoustachial area dull rufous-chestnut, neck side buffy tan with underlying black-and-white scaling; chin buffy ochre, throat to upper breast matt-black, upper breast feathers with long dull whitish to buffy tips (creating scaly effect), this pattern contiguous with neck side and continuing weakly down upper flanks, the tips broadening on lower breast so that rest of underparts plain buffy ochre, warmer on flanks; iris yellowish-white to yellowish; upper mandible brown, lower mandible bluish-white; legs flesh-white. Differs from similar *I. maxima* in having crown uniform black, lores chestnut-rufous, ear-coverts dark chestnut, cheek to chin and throat black, breast with black-and-whitish scaling, mantle and neck sides more rufescent, tail more square-ended. Sexes similar. Juvenile has head browner than adult, white spots

on upperparts smaller, absent on rump and uppertail-coverts, throat browner with less sharp edgings. Race *griseicauda* is like nominate but has more grey in tail, *maculipectus* has buffier supercilium and paler, rufous-chestnut ear-coverts, rufous colour extending to submoustachial area, more buff and fewer white spots on upperparts; *artemisiae* is like last, but almost lacks supercilium and has black ear-coverts (joining black on throat) with pale area behind, narrower and more extensive blackish barring below. **VOICE.** Song consists of repeated rich mellow fluty phrases, e.g. "wu-it, wu-u, wu-u, wi-u", "w'you, w'you, uu-i, w'you, uu-i" and "w'you, uu-wi'ii, uwa"; alternatively as mellow, leisurely, descending "fweér-fweér-fwúr-fwúr", and more strongly modulated "fuwéé-fuwéé-füu" or "fuwit-fuwéé, fuwit-fuwéé"; often joined by more jarring, rising "fu'u'wheen!" (first part slightly tremulous, second more nasal) from presumed females during duets. Calls include repeated, strident, screechy, guttural upsturred "schüwéé!".

**Habitat.** Undergrowth in high-elevation forest, light open mixed forest with undergrowth, thick rhododendron scrub and bushes bordering fields; at 2135–3660 m, rarely to 4100 m, and in China down to 1100 m. In Bhutan, mainly 2800–3200 m and favouring fir forest in summer; in winter, uses wider range of conifer habitats, including blue pine forest, down to 2200 m.

**Food and Feeding.** Insects, fruit and seeds; diet appears almost entirely vegetarian, but nestlings fed with insects. Inconspicuous. Keeps in pairs and in small family parties of 3–8 individuals; often associates with *Trochalopteron affine*. Forages on ground and in bushes.

**Breeding.** May–Jun in India and Xizang (S China). Nest reportedly a large, loose cup, made of twigs, dry grasses, bamboo leaves, roots, moss and ferns, lined with rootlets, placed within 2 m of ground in bush, small tree or clump of ferns and grass. Clutch at least 2 eggs, delicate pale blue or deep blue-green, sometimes few chocolate-brown specks. No information on incubation and nestling periods. Nestlings may leave nest long before full-grown.

**Movements.** Resident; winter dispersal to lower elevations reported from Bhutan.

**Status and Conservation.** Not globally threatened. Fairly common in Nepal, including in Langtang National Park. Frequent in Bhutan, but usually singly or with very few together. Fairly common in India, where present in and/or near Eaglenest Wildlife Sanctuary, in Arunachal Pradesh. Fairly common in N Myanmar and in China.

**Bibliography.** Ali & Ripley (1972), Ali *et al.* (1996), Anon. (2004c), Bangs (1932), Berlioz (1930), Cheng Tsohsin (1987), Cheng Tsohsin *et al.* (1963), Choudhury (2003), Dowell *et al.* (1997), Eck (1987), Gaston (1989), Grimmett *et al.* (1998), Huang Qiang, Deng Heli & Mao Ke (1995), Huang Qiang, Huang Yongzhao & Deng Heli (1993), Hume & Oates (1889), Inskipp & Inskipp (1991, 1993b), Inskipp *et al.* (2000), King (1989b), Kleefisch (2004), Li Guiyuan, Liu Liangcai *et al.* (1976), Li Guiyuan, Zhang Qingmao *et al.* (1994), Ludlow & Kinnear (1937, 1944), Martens & Eck (1995), McCarthy (2006), Meyer de Schauensee (1984), Neff (2004), Rasmussen & Anderson (2005), Robson (2000), Rothschild (1926), Singh (1995), Smythies (1940, 1949), Spierenburg (2005), Stanford (1941), Stanford & Mayr (1941), Stevens (1923), Stresemann (1923c), Zhang Quntan *et al.* (1994), Zheng Zuoxin *et al.* (1983).

Songs of first type described also as a striking, rich wolf-whistle, "wheéééééééééé!" (upsturred and then downslurred at very beginning, rest strongly upsturred), with simpler and also more complex variants. Calls include fairly short subdued buzzy "jrrrrr-rrr-rrr..." and harsh, rather liquid, quite buzzy "chee-cher-rrrr" or "jo-jorrrrr"; also as complaining, buzzy "bzze-zrrr-zrrr-zrrr" (downslurred notes), often in short bursts, and sometimes ending with prolonged, descending musical, hollow chirring: "chrr-chrr-rrrr-rrrr".

**Habitat.** Rather dense understorey and undergrowth of more open broadleaf evergreen forest, secondary growth, scrub and bushes bordering forest, bamboo, often near streams, at 900–2440 m; locally is common 500 m in SE Arunachal Pradesh (India).

**Food and Feeding.** Insects, berries and seeds. Usually found in pairs or in small family parties, occasionally singly; in Bhutan, may occur in small flocks of up to ten individuals in Jan–Apr. Known close to ground in dense cover, very skulking.

**Breeding.** Apr–Jul. Nest reportedly a bulky, compact or loose cup, made of dry bamboo or other leaves, creepers, tendrils, fine twigs, grasses, roots and moss, lined with black fibrous roots, black fibres and rootlets, placed 1.2–1.8 m above ground in bush or tangle of creepers. Clutch 2–4 eggs, usually 3, bright pale, somewhat greenish-tinged blue to deep blue. No information on incubation and nesting periods. Brood parasitism by Chestnut-winged Cuckoo (*Clamator coromandus*) occurs.

**Movements.** Resident; some dispersal to lower elevations in mid-winter noted in Bhutan.

**Status and Conservation.** Not globally threatened. Scarce and local in Nepal. Frequently recorded in Bhutan in C & E valleys; near Zhemgang, density of 0.6 territories/km of road noted at 1600–1900 m. In India, uncommon in Himalayas but more frequent in NE hills, with populations present in Buxa Tiger Reserve, in West Bengal, and in Eaglenest Wildlife Sanctuary, Mouling National Park and Namdapha National Park (scarce), in Arunachal Pradesh. Rare in China. Generally uncommon in SE Asian range.

## 251. Brown-cheeked Laughingthrush

### *Trochalopteron henrici*

**French:** Garrulaxe de Henri **German:** Prinzenhäherling **Spanish:** Charlatán de Henri  
**Other common names:** Prince Henri's/Henry's Laughingthrush

**Taxonomy.** *Trochalopteron henrici* Oustalet, 1892, "So", Tibet; error = Aio and Sutu, Xizang, China. Genus traditionally subsumed in *Garrulax*. Has been considered conspecific with *T. elliotii*, although differences considerable, and also with geographically distant *T. morrisonianum*. Form described as "gucenense", from Chayul Valley, in Qamdo (SE Xizang), has been judged to be a hybrid between present species and *T. elliotii*. Monotypic.

**Distribution.** S & SE Xizang (from Mt Everest region E to R Salween), in S China; one record extreme NE India (NE Arunachal Pradesh).

**Descriptive notes.** 24.5–26 cm; 60–70 g. Medium-sized brownish-grey laughingthrush with blue-grey wings and long and heavily graduated white-tipped tail, chocolate-chestnut mask and bold whitish malar. Crown and upperparts are dull brownish-grey, upperwing with black primary coverts, flight-feathers with slate-coloured tips and blue-grey fringes, dull rufous-brown patch on primary bases; tail blue-grey with bold white tips; mask (lores to top of eye, ear-coverts, cheek and upper submoustachial and malar areas) chocolate-chestnut, bordered vaguely above by indistinct white supercilary line (sometimes absent), below by bold whitish

lower submoustachial and malar stripe extending under ear-coverts; chin and throat brownish-grey, becoming paler and greyer on breast and flanks, with very indistinct brownish streaking on breast, mid-belly with rufous tinge, shading to mid-chestnut on lower flanks, thighs and vent; iris crimson; bill pinkish-brown to nut-brown; legs lead-grey to dull pinkish-brown. Sexes similar. Juvenile is browner than adult. **Voice.** Songs clear and repeated every 4–10 seconds, "wichi-pi-choo", "whi-pi-choo" or "whi-choo-it", often given antiphonally with a cheerful "dieu-dieu" or "peu-peu" (presumably from females); song has been described also as a loud, clear, slurred, whistled "fwéééa-tiyúúú".

**Habitat.** Scrub and bushes, including pea trees (*Caragana*), bordering forest and in gulleys, open forest, human habitation and crop fields, in both arid and moister areas; at 1980–4570 m.

**Food and Feeding.** No information on diet; presumably invertebrates and some vegetable matter. Found in pairs during breeding season, otherwise in small parties, sometimes associating with *T. affine*. Forages mostly on ground.

**Breeding.** May–Jul. Nest described as a rather untidy cup made of dried grass, dead leaves, strips of birch bark and moss, lined with dry twisted grass, placed in bush or hedge not far above ground; up to 80% of nests found in same species of plant as that used for nesting by *Babax waddelli*. Clutch 2–3 eggs, pale blue with sparse dark markings, said to be like those of *T. erythrocephalum*. No other information.

**Movements.** Resident. Presumably some minor altitudinal movements.

**Status and Conservation.** Not globally threatened. Locally common in Xizang, where density in excess of 2 birds/ha, much higher than that of *Babax waddelli* (which likewise confined to Tibetan Plateau). In adjacent NE India, probably a rare resident in NE Arunachal Pradesh, where one record (Jan 1995).

**Bibliography.** Ali & Ripley (1972), Berlioz (1930), Grimmett *et al.* (1998), Li Dehao *et al.* (1978), Lu Xin (2004), Ludlow (1951), Ludlow & Kinnear (1944), Meyer de Schauensee (1984), Oustalet (1893), Rasmussen & Anderton (2005), Robson (1986), Zheng Zuoxin *et al.* (1983).

## 252. Elliot's Laughingthrush

### *Trochalopteron elliotii*

**French:** Garrulaxe d'Elliot **German:** Elliotthäherling **Spanish:** Charlatán de Elliot

**Taxonomy.** *Trochalopteron elliotii* J. Verreaux, 1870, "les montagnes du Thibet chinois" = western Sichuan, China.

Genus traditionally subsumed in *Garrulax*. Has been considered conspecific with *T. henrici*, although differences considerable; form described as "gucenense", from Chayul Valley, in Qamdo (SE Xizang), has been judged to be a hybrid between these two. Proposed races *prjevalskii* (from E Qinghai and Gansu E to Hubei, S to N Yunnan and W Guizhou) and *bonvaloti* (from near Lamda, Xizang) regarded as indistinguishable from birds elsewhere in range. Monotypic.

**Distribution.** China from E Qinghai and adjacent N Gansu (SE Qilian Shan) E to SW Nei Monggol (Helan Shan), S to SE Xizang, C Yunnan, W Guizhou, S Ningxia, S Shaanxi and W Hubei, and extreme NE India (extreme E Arunachal Pradesh).

**Descriptive notes.** 23–25.5 cm; 40–72 g. Medium-sized long-tailed laughingthrush, grey-brown with pinkish-grey crown, golden-olive wing and tail fringes and chestnut vent. Crown is pinkish-tinged milky grey, shading to dull brownish olive-grey on upperparts, with tiny dull greyish and dark spots scattered on mantle; outer primaries edged whitish-grey, inner primaries edged orangish, rest of upperwing with yellow-tinged golden-olive fringing, greyish tertials; tail greyish with strong golden-olive wash, most intense along outer edges of feathers, tips white; face (lores, supercilary area, cheek and ear-coverts) blackish brownish-grey; chin, submoustachial area and neck side to belly pinkish-tinged greyish-brown, with tiny dotted whitish edges on feathers of neck side and breast side, lower belly and thighs pinkish-chestnut, vent chestnut; iris whitish-yellow to dark cinnamon; bill blackish; legs fleshy-yellowish. Sexes similar. Juvenile lacks white specks on shoulders and mantle. **Voice.** Song loud, clear and quite high-pitched, usually consisting of 3-note phrases repeated at intervals of 3–9 seconds, the final note often with somewhat wavering quality, e.g. "whi-pi-piu", "whi-pi-piuw" or "whi-pi-piuru", sometimes accompanied by an antiphonal "peu-peu-peu" (presumably from female); songs have been described also as a loud, elastic, clear whistled "fwééé-aa-wóó" (first note greatly stressed) repeated every few seconds, a quicker, more evenly stressed "fwééé-úú-wit", and a more broken-up "fuwít, tiyútiyú". Calls include subdued and quite high-pitched chuntering.

**Habitat.** Thickets, undergrowth and bamboo at or above timber-line, more open broadleaf forest, mixed broadleaf-pine forest and juniper forest; often close to human habitation, gardens, crop-field borders, etc. At 1000–4200 m; occupies one of the widest altitudinal ranges of any laughingthrush.

**Food and Feeding.** No information on diet; presumably invertebrates and some vegetable matter. Occurs singly, in pairs or in small parties, sometimes in larger groups of up to 20 individuals in winter. Forages typically on or close to ground. Quite confiding near human settlements. Habits identical to those of *T. henrici*.

**Breeding.** Jun–Sept. Nest reportedly a fairly crude cup made of moss stalks, leaves and other dead vegetation, lined with fine twigs, placed 0.5–3.5 m above ground in small tree or bush. Clutch 2–3 eggs, pale blue-green with some blackish-brown spots and irregular lines. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Common in China, e.g. at Emei Shan Protected Scenic Area, in Sichuan. Probably rare and local in India.

**Bibliography.** Anon. (2004c), Bangs & Peters (1928), Berlioz (1930), Cheng Tsohsin (1987), Cheng Tsohsin *et al.* (1963), Deditius (1897), Dowell *et al.* (1997), Grimmett *et al.* (1998), Hornslov (1991), Huang Qiang, Deng Heli & Mao Ke (1995), Huang Qiang, Huang Yongzhao & Deng Heli (1993), King (1989a, 1989c), King & Peng Jitai (1991), Lee Tehhow *et al.* (1965), Li Dehao (1981), Li Guiyuan, Liu Liangcai *et al.* (1976), Li Guiyuan, Zhang Qingmao, Luo Jiaze *et al.* (1994), Li Guiyuan, Zhang Qingmao & Wen Anxiang (1993), Lönnberg (1924), Meyer de Schauensee (1984), Oustalet (1893), Rasmussen & Anderton (2005), Riley (1926), Robson (1986), Schäfer & Meyer de Schauensee (1938), Sien Yaohua *et al.* (1964), Singh (1995), Stone (1933), Stresemann (1923c), Tan Yaokuang & Cheng Tsohsin (1964), Vaurie (1972), Wang Zhijun & Wei Tianhao (1983), Wu Zhikang, Lin Qiwei *et al.* (1986), Wu Zhikang, Yang Jiongli & Xu Weishu (1981), Ye Xiaodi & Wang Zuixiang (1993), Yu Zhiwei *et al.* (1986), Zhang Quntan *et al.* (1994), Zheng Zuoxin & Qian Yanwen (1973), Zheng Zuoxin *et al.* (1983).

## 253. Variegated Laughingthrush

### *Trochalopteron variegatum*

**French:** Garrulaxe varié **German:** Buntflügelhäherling **Spanish:** Charlatán Variegado

**Taxonomy.** *Cinclosoma variegatum* Vigors, 1831, Simla, Himachal Pradesh, India.

Genus traditionally subsumed in *Garrulax*. Three subspecies recognized.

**Subspecies and Distribution.**

*T. v. nurlistani* (Paludan, 1959) – NE Afghanistan.

*T. v. simile* Hume, 1871 – N & NE Pakistan E to N India (N Himachal Pradesh).

*T. v. variegatum* (Vigors, 1831) – S Himachal Pradesh E to Uttaranchal Pradesh, W & C Nepal and adjacent S China (S Xizang).

**Descriptive notes.** 24–26 cm; 57–79 g. Medium-sized olive and buffy laughingthrush with whitish lower face, broad black mesial stripe and grey, black and white wings and tail. Nominative race has forehead dull buff, shading to vaguely streaked pale brownish-grey on crown; upperparts ochre-tinged greyish-olive, upperwing with strong cinnamon fringes of greater coverts, black primary coverts and markings on bases of secondaries, black tertials with whitish on outer webs, pale grey and pale ochrous-grey wing fringing; blackish tail with broad greyish subterminal band and white tip; lores, spot at base of lower mandible and area

around eye (except for tiny white postocular flash) blackish, shading greyer on ear-coverts; rest of submoustachial area buff, shading backwards to whitish, with whitish-tipped blackish feathers on lower ear-coverts; chin and central throat blackish, breast and belly ochrous grey-brown or buffish-grey, shading to ochrous-rufous on lower belly, thighs and vent; iris pale yellow or pale yellow-green to pale yellowish-brown or brown, dull blackish to dark brown, yellow base of lower mandible; legs pale reddish orange-brown or pale brown to flesh-coloured. Sexes similar. Juvenile is slightly warmer and less distinctly patterned overall than adult. Race *simile* differs from nominate in having uniform silvery-grey fringing on outer tail, primaries and secondaries, paler and duller forehead, greyer upperside, breast and flanks, and whiter throat side; *nurlistani* is like last but greyer

overall, with darker crown and nape. **Voice.** Song consists of repeated loud, musical, far-carrying whistled phrases, e.g. "weet-a-weer", "weet-a-woo-weer", "zdeep-deeu-ee-weeh" and "deeo-pee-weeh", and shrill, musical "p'ti-pieyou" and "p'tee-weet". Songs have been described also as sweet, rich, hurried complex whistled phrases, consisting of strongly downslurred notes, preceded by a few quick introductory strokes, "chitilurk-fwüürk-(urk)" ("fwüürk" greatly stressed), and "fzeep, fwur-fwilliféer" (short, weak first note, others strongly upslurred and then downslurred, last 2 speeded up, prolonged). When alarmed, utters subdued muttering and squealing notes.

**Habitat.** Open forest of fir and birch or oak with dense rhododendron and ringal bamboo growth and bushes; dwarf rhododendron at or above tree-line, patches of *Viburnum* at forest edge, various types of dense jungle and undergrowth, particularly in winter, open willow groves; occasionally enters gardens. Found at 1800–4200 m in summer; some descend locally as low as 1000 m during extreme winter weather.

**Food and Feeding.** Insects, fruit and berries. In pairs during breeding season; otherwise in parties of up to 20 or more birds. Forages among bushes and on ground, but often ascends trees. Not shy.

**Breeding.** Apr–Aug. Nest described as a rather compact, sometimes untidy, but usually rather shallow cup, made of coarse grasses, dead leaves, strips of birch bark, roots, twigs, moss, finer and softer grasses and fir needles, lined with rootlets, fine grasses and pine needles, placed 0.15–6 m above ground in bush, small tree or lower branch of larger tree, sometimes in thick grass tuft. Clutch 2–5 eggs, usually 3–4, pale, rather dingy blue-green to blue, blotched, spotted and speckled with liver-red, reddish-brown, yellowish-brown, pale purple or purplish-red; incubation by both sexes. No information on duration of incubation and nestling periods. Occasional brood parasitism by Indian Cuckoo (*Cuculus micropterus*) reported.

**Movements.** Resident. Relatively minor altitudinal displacements during harsh winter weather; both nominate race and *simile* reported (sometimes in same flock) in winter from Kangra area of Himachal Pradesh, in India.

**Status and Conservation.** Not globally threatened. Locally common in Pakistan, and fairly common in Palas Valley, in North-West Frontier Province. Common in Nepal, with significant proportion of world population judged to be in Shey-Phoksundo National Park, where species is locally common. Locally fairly common in India; common in Nanda Devi Biosphere Reserve and fairly common in Dehra Dun valley, in Uttaranchal, and common (mainly in dense nullahs) in Majhatal Harsang Wildlife Sanctuary, in Himachal Pradesh.

**Bibliography.** Ali & Ripley (1972), Bates & Lowther (1952), Bertioz (1930), Fischer (1995), Gaston *et al.* (1994), Grimmett & Robson (1986), Grimmett *et al.* (1998), Hume & Oates (1889), Inskipp & Inskipp (1991), Martens & Eck (1995), Meyer de Schauensee (1984), Mishra (1997), Priemé & Oksnebjerg (1994), Raja *et al.* (1999), Rasmussen & Anderton (2005), Roberts (1992), Sankaran (1994), Singh (2000), Stuart Baker (1922), Zheng Zuoxin *et al.* (1983).

## 254. White-whiskered Laughingthrush

### *Trochalopteron morrisonianum*

**French:** Garrulaxe du Morrison **German:** Weißbarthäherling **Spanish:** Charlatán de Morrison  
**Other common names:** Taiwan Laughingthrush

**Taxonomy.** *Trochalopteron morrisonianum* Ogilvie-Grant, 1906, Mount Morrison, Taiwan. Genus traditionally subsumed in *Garrulax*. May form a superspecies with *T. affine*. Has been considered conspecific with latter or with *T. henrici*, but basis for such treatments poor. Monotypic.

**Distribution.** Taiwan.

**Descriptive notes.** 25–28 cm; mean 75 g. Fairly large laughingthrush, dark rufous-brown and grey with olive-gold wingpanel, white submoustachial stripe, and vague whitish scaling on upperparts and breast. Forehead is dull greyish-buff, shading to buffy grey on crown, to dull dark rufous with ochre tinge and indistinct narrow white scales on mantle and back, and to plain dark rufous-tinged olive-grey on rump and scapulars; primary coverts blackish, wing fringes and tertials mid-grey, with broad dull rufescent olive-gold wingpanel; tail like upwelling or darker grey, with extensive golden-olive on outer webs, brighter at base;

lores whitish, face (supercilium, ear-coverts, area round eye and cheek) dull dark chestnut, with white postocular lateral crownstripe and broad submoustachial stripe; chin and throat vaguely streaked ochrous-buff on dark brown, breast as mantle, mid-belly, flanks and thighs as rump, lower belly and vent pale chestnut; iris brown; bill pale brown; legs dark flesh. Sexes similar. Juvenile apparently undescribed. **Voice.** Song a rich clear whistle, "wit-chi'wi" or "wip-chi'ri", repeated every 3–5 seconds; sometimes answered with downward trill by another bird. Also has excited giddy laughter, "hee-hee-hee-hé, hee-hee", and melodious loud bell-like whistles, "di, di, di...". Very quiet "tsip" calls while foraging, also some quiet whistles and chirps.

**Habitat.** Undergrowth and lower tree stratum in coniferous forest, mixed broadleaf deciduous and coniferous forest, open forest with clearings, dwarf and secondary coniferous scrub, bamboo, junipers, shrubby by trails and mountain roads, near mountain cabins, brush above tree-line. Occurs at 1800–3300 m, some descending locally as low as 1000 m during hard winter weather; recorded between 1475 m and 3425 m in N Taiwan.

**Food and Feeding.** Primarily insects, berries, seeds and flower petals. Consumes more invertebrates and flower petals and takes larger food items (1–6 cm) in breeding season compared with non-breeding season. Also, exploits different parts of habitat inside breeding season: forages at both lower (0–2 m) and higher (8–14 m) levels than in non-breeding season, on shorter (0–2 m) and taller (6–14 m) plants, on smaller (0–5 cm diameter at breast height) and larger (15–40 cm) trees, and on smaller (0–1 cm diameter) branches. Also scavenges around rubbish piles. Males tend to forage higher up (above 8 m) in trees than do females; forages also on ground.

**Breeding.** Mar–Aug. Monogamous. Nest a cup made of grass blades, stems and roots, lined with rootlets, decorated with a few small leaves, placed c. 1.2 m above ground in areas in territory with highest tree density, or in bush. Clutch 2 eggs, pale milky blue to sky-blue, sparsely marked with greyish-black blotches. No other information.

**Movements.** Resident. Minor altitudinal movements recorded.

**Status and Conservation.** Not globally threatened. Restricted-range species; present in Taiwan FBA. Fairly common within elevational range; common, or more visible, in coniferous zones. In Yushan National Park, recorded densities of 2–47 birds/ha in grassland, 2–21/ha in pine woodland, 9–1/ha in mixed coniferous forest and 2–21/ha in spruce forest.

**Bibliography.** Bertioz (1930), Cheng Tsohsin (1987), Ding Tzungsu *et al.* (1997), Fang Woeihong (2005), Hachisuka & Udagawa (1950, 1951), Koh Chaonien & Lee Peifen (2003), Ogilvie-Grant (1906), Severinghaus & Blackshaw (1976), Stattersfield *et al.* (1998), Vaurie (1954b), Yang Xiuying (1991), Yen Chungwei (1990), Yu Shuchun (1999).

## 255. Black-faced Laughingthrush

### *Trochalopteron affine*

**French:** Garrulaxe à face noire

**German:** Schwarzscheitelhäherling

**Spanish:** Charlatán Carnegiro

**Taxonomy.** *G[arrulax] affinis* Blyth, 1843, central Nepal.

Genus traditionally subsumed in *Garrulax*. May form a superspecies with *T. morrisonianum*. Has been considered conspecific with latter, but basis for such treatment poor. Six subspecies recognized.

**Subspecies and Distribution.**

*T. a. affine* (Blyth, 1843) – W & C Nepal and adjacent S China (S Xizang).

*T. a. bethelae* (Rand & Fleming, 1956) – E Nepal E to Bhutan and NE India (Arunachal Pradesh) and adjacent S China (S & SE Xizang).

*T. a. oustaleti* (E. J. O. Hartert, 1909) – N Myanmar and S China (NW Yunnan and adjacent SE Xizang).

*T. a. blythii* J. Verreaux, 1870 – S Gansu S to SW Sichuan (N of Muli region), in SC China.

*T. a. muliense* (Rand, 1953) – SW Sichuan (Muli Region) S to NW Yunnan (Lijiang Range), in S China.

*T. a. saturatum* (Delacour & Jabouille, 1930) – C & SE Yunnan and extreme NW Vietnam (NW Tonkin).

**Descriptive notes.** 24–26 cm; 52–85 g. Fairly large, dark brownish laughingthrush, scaled above and streaked below pale grey, with blackish-brown head and short rounded white submoustachial patch. Nominative race has crown dark brown, paler on nape, and rufescent mid-brown on mantle, shading to rufescent olive on upperparts with vague grey subterminal smudges and neat narrow dark scale-shaped tips; rump and uppertail-coverts dull pale chestnut; primary coverts black, flight-feathers fringed pale grey with broad golden-olive wing flash, tail dull golden-olive basally, grey distally; side of face (supercilium and rear lateral

eral crownstripe, lores, cheek and ear-coverts) blackish, with white vertical patch behind ear-coverts and bolder creamy-white drop-shaped upper submoustachial and malar patch; chin blackish, throat to lower submoustachial area and breast brownish-tan with buffier centres and greyish edges (creating indistinct streaks), shading on belly, flanks and vent to buffy olive; iris brown or olive-khaki; bill horn-black; legs pinkish-brown or horn-brown. Sexes similar. Juvenile is browner-crowned than adult, with no white neck patch, and more uniform brown body plumage. Race *bethelae* tends to be blacker-headed, browner-backed, with richer brownish-tan breast and more ochrous flanks and vent than nominate; *oustaleti* is like previous, but with darker grey streaking below and darker, more uniform underparts overall (pattern slightly more scaly); *saturatum* is very like last but darker and duller overall, more extensively blackish on head (black extending farther onto throat), white submoustachial and neck patch less extensive, outer fringes of secondaries duller; *muliense* has slightly greyer-tinged crown and greyer, floury wash on underparts, pattern scaller; *blythii* is like last, but browner on mantle, back, neck and underparts, with outer fringes of secondaries dull moss-green. **Voice.** Song consists of repeated loud, shrill, rather high-pitched, quickish phrases, e.g. "wiee-chiweeo", "wiee-chweeui" and "wiee-weeoo-wi" ("wiee" shriller, higher, rising), repeated every c. 7 seconds; those of race *bethelae* said to be richly modulated, strident, whistled "fwüweeo-wheoóóówhéet!" etc., may start with few higher, tinkly notes, e.g. "tertinkit-tutur-wheoóóówhéet!". Calls include continuous, rather high rattling, and low conversational chuckles, have been transcribed also as gruff low rattles that often begin or end in harsh metallic upslurs, e.g. "trrrrt, trrt, trrrrt-krvlt, trrrrt", wheezy, thin purrs and whines, and mewing. Very noisy when excited.

**Habitat.** High-altitude habitats, including bushy undergrowth in broadleaf evergreen, coniferous and mixed forest, scrub oak and bamboo in mixed oak and conifer, birch and fir or rhododendron forest, juniper and stunted rhododendron, conifer and birch thickets, bamboo, dwarf rhododendron and shrubby above timber-line. Found at 2350–4600 m (mainly above 2300 m), some descending locally in winter as low as 1630 m; in China, locally down to 1500 m during breeding and as low as 500 m in winter; in Bhutan possibly breeds only above 3000 m, and in winter apparently absent above 3200 m and found down to 1800 m (occasionally 1300 m).

**Food and Feeding.** Insects, including beetles (Coleoptera); also berries and fruits, including wild strawberries (*Fragaria*), crabapples (*Malus*) and ginseng (*Heptapleurum*), and seeds, including those of brambles (*Rubus*), aromatic wintergreens (*Gaultheria*) and viburnums (*Viburnum*). Noted also as feeding on a vervain (*Clerodendron*). Found in pairs during breeding season; otherwise in small parties, although up to 30 recorded together, and may associate with other species, including *Fulvetta vinipectus*, in bird waves. Forages on or near ground, and sometimes as high as crowns of small trees.

**Breeding.** Apr–Aug. Nest a large but neat cup, externally made of moss and fine twigs, internally of dry rhododendron leaves, root fibres and a few grass blades, lined with fungus rhizomorphs, root fibres and birch-bark paper, placed 1–2.5 m above ground in bush (e.g. rhododendron or viburnum). Clutch 2–3 eggs, blue to slightly greenish-blue with a few blackish-brown to purplish-black spots, blotches and scrawls; in captivity, incubation period 14–15 days, fledging period 14–16 days (sometimes to 21 days).

**Movements.** Resident; post-breeding altitudinal displacements at least in Bhutan, where occurs at lower levels Dec–Feb, and in China.

**Status and Conservation.** Not globally threatened. Common in Nepal, including Langtang National Park. Abundant in alpine and temperate zones in Bhutan. Common in India, where present in Buxa Tiger Reserve (West Bengal) and in and/or near Eaglenest Wildlife Sanctuary (Arunachal Pradesh). Locally common in SE Asian range. Generally uncommon in China.

**Descriptive notes.** 26 cm; 67–75 g. Variable dark laughingthrush with silvery-edged ear-coverts. Nomininate face has crown and nape chestnut, upperparts plain dark olive-tinged grey-brown, palest on mantle and neck side, greater upperwing-coverts chestnut-fringed brown, primary coverts black, flight-feather fringing and tail olive greyish-yellow; lores, frontal supercilium, cheek, malar and

chin blackish, rear supercilium and ear-coverts dull silvery with maroon streaks; lower throat and upper breast dull maroon, rest of underparts dirty ochrous-olive, shading darker lower down and greyer towards sides; iris greyish to dark brownish-grey; bill dark brownish; legs fleshy-brown to dark purplish-grey, sometimes tinged yellowish. Differs from similar *T. erythrocephalum* and *T. chrysopetrum* in unspotted back, dark primary coverts, more extensive silvery edges on ear-coverts, dark-streaked grey supercilium spreading to upper neck side, black chin and malar area, and olive-tinged lower underparts. Sexes similar. Juvenile apparently undescribed. Race *ramsayi* is like nominate, but has brighter greenish wing fringing, more extensive and brighter yellowish-tan on lower throat to belly; *schistaceum* is purer grey above and on belly, with very slight scaly effect on breast, blacker-tinged ear-coverts; *subconnectens* has dusky-brown ear-coverts with silvery edgings, tan-washed olive-grey breast and belly with scaly brownish-grey edges (creating distinct scaly effect); *connectens* resembles last, but scaly effect below even more pronounced, has yellowish-olive wing fringing (including primary coverts). Voice. Song in NW Thailand loud and quite liquid "wi-wiwioo", "wu-weeoo" or "tu-tweeoo", with more emphasis on first note, repeated every 2–10 seconds. Also a quickly delivered "u-wip-weeoo", with faint introductory note; "weeoo-wiwip", with rising first note; sometimes a very fast "wiu-wip" or "wip-wip". Moaning, slightly husky, clear mewing "weeaa-ao", "waaaow-ow", "waaaa" or "aoaaaa" may be given antiphonally (presumably by female).

**Habitat.** Broadleaf evergreen, pine and mixed broadleaf-pine forests, secondary growth, scrub and grass, bamboo brakes; at 1065–2565 m, but down to 610 m in S Myanmar (C Tenasserim). **Food and Feeding.** No information on diet; presumably invertebrates and some vegetable matter. Typically encountered when foraging singly, in pairs or in small groups, on or close to ground; occasionally ascends moss-cloaked and lichen-covered tree branches. **Breeding.** Mar–Aug. Nest, built by both sexes, a bulky well-made deep cup, of moss and/or dry leaves, lined with black hair-like fungus, placed in fork of sapling or tree branch, in tangle of creepers or in tree-fern or bamboo. Clutch 2 eggs (C Tenasserim), sky-blue with sepia blotches and spots. No other information.

**Movements.** Resident. **Status and Conservation.** Not assessed. Generally common. Rare in Yunnan, in China. In Thailand, common in Doi Chiang Dao Wildlife Sanctuary and Doi Inthanon and Doi Suthep-Pui National Parks. Common in Nakai-Nam Theun National Biodiversity Conservation Area, in Laos. Present in Pu Mat Nature Reserve and common in Fan Si Pan National Park, in Vietnam. **Bibliography.** Berlioz (1930), Bingham (1903), Cheng Tsohsin (1987), Collar (2006), David-Beaulieu (1944), Davidson (1998), Deignan (1938, 1963), Delacour & Jabouille (1931a), Eames *et al.* (2001), Evans & Timmins (1998), Hopwood (1919), Hume & Davison (1878), Lekagul & Round (1991), Meyer de Schauensee (1934, 1946, 1984), Oates (1894), Peng Yanzhang *et al.* (1979), Riley (1938), Rippon (1901), Robertson (1993), Robson (2000), Rothschild (1926), Smith *et al.* (1940, 1943), Smythies (1986), Tizard *et al.* (1997), Tordoff, Lê Manh Hùng *et al.* (2002), Tordoff, Lê Trong Dat *et al.* (2001), Wang Zhijun & Wei Tianhao (1983), Yang Lan (2002), Zheng Zuoxin *et al.* (1983).

## 259. Malayan Laughingthrush

### *Trochalopteron peninsulæ*

**French:** Garrulaxe de Malaisie **German:** Rostschulterhäherling **Spanish:** Charlatán Malayo

**Taxonomy.** *Trochalopteron peninsulæ* Sharpe, 1887, Larut Range, Perak, Peninsular Malaysia. Genus traditionally subsumed in *Garrulax*. Until recently, this species and *T. chrysopetrum*, *T. melanostigma* and sometimes *T. ngoclinhense* were regarded as conspecific with *T. erythrocephalum*. Monotypic.

**Distribution.** Extreme S Thailand and Peninsular Malaysia.

**Descriptive notes.** 25.5–26.5 cm; 58–72 g. Top of head is maroon-chestnut, edged slightly blackish on lores and superciliary area to above eye, with postocular superciliary area, neck side and nape dull dark silvery grey; upperparts dull olive-tinged chestnut-brown, tail dull slaty grey (with paler olive-tinged sheen in some lights); upperwing with greater coverts dark chestnut, primary coverts black, flight-feathers olive-green with greenish-yellow fringing; ear-coverts and cheek dark chestnut with pinkish-grey sheen, submoustachial area dull chestnut-brown with vague blackish flecking; chin to breast chestnut-brown, shading slightly to

more rufous-brown on belly and to rich dirty rufous-tinged greyish-brown on flanks, thighs and vent; iris yellowish to brown, indistinct white eyering; bill blackish; legs brownish-black to brown. Differs from similar *T. melanostigma* in having maroon-chestnut crown, reduced black on lores and chin, reduced silvery delineation of ear-coverts, dark silvery-grey hindcollar (extension from neck side), white eyering, plain dull chestnut-brown mantle and scapulars to upperpart-coverts, plain chestnut-brown throat to belly. Sexes similar. Juvenile has crown duller than adult, with grey patches on sides of neck less distinct and more suffused with brownish. Voice. Sings with clear and far-carrying "wip-weeoo" or "wiw-weeoo" and similar (with rising, stressed second note). Also a quickly delivered "wip-wi-eeoo" (short first note, somewhat rising middle note).

**Habitat.** Understorey and bamboo in broadleaf evergreen forest, secondary growth, scrub and grass, from 1065 m to at least 1830 m.

**Food and Feeding.** Mainly insectivorous, consuming beetles (Coleoptera) and grubs; seeds also eaten. Typically in pairs or in parties of 4–5 individuals. Forages usually on or near ground, but occasionally ascends trees.

**Breeding.** Jan–May. Nest a sturdy deep cup made of dry leaves, bryophytes, plant fibres and rootlets, lined with fine fibres, placed up to 1.5 m above ground in tree-fern, sapling or hanging lianas. Clutch 1–2 eggs, blue with a few blackish spots. No other information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Common within rather restricted range; common e.g. at Bukit Fraser and in Taman Negara National Park at Mt Tahan.

**Bibliography.** Berlioz (1930), Collar (2006), Deignan (1963), Glenister (1951), Lekagul & Round (1991), Madoc (1956), Madoc & Allen (1952), Medway (1972), Medway & Wells (1976), Robinson (1928), Robson (2000).

## 260. Golden-winged Laughingthrush

### *Trochalopteron ngoclinhense*

**French:** Garrulaxe du Ngoc Linh **German:** Goldflügelhäherling **Spanish:** Charlatán Alidorado

**Taxonomy.** *Garrulax ngoclinhensis* J. C. Eames *et al.*, 1999, Mount Ngoc Linh, Kon Tum Province, Vietnam.

Genus traditionally subsumed in *Garrulax*. Closely related to *T. erythrocephalum*; has been treated as conspecific, but is strongly distinct. Monotypic.

**Distribution.** C highlands of C Annam, in Vietnam.

**Descriptive notes.** 27 cm. Medium-sized, dark grey, faintly scaly-breasted laughingthrush with chestnut crown and broad golden wing fringing. Forehead is dark grey with maroon tinge, forehead to mid-crown dark grey with blackish streaks, mid-crown to nape chestnut, richer towards rear; upperparts dark olive-tinged grey, upperwing with greater coverts broadly tipped chestnut, primary coverts black, flight-feather fringes golden-yellow; tail slaty, outer feathers with dull golden-ochre fringes; lores to above and below eye and chin blackish, shading to pinkish-stained darkish grey on ear-coverts and throat, to dark grey with broad mid-grey scaling on breast, and to plain dark olive-grey mid-belly and dark grey flanks, thighs and vent; iris dark brown to blackish; bill blackish-horn; legs dark brown. Sexes similar. Juvenile undescribed. Voice. Song undescribed. Only documented call is a double-noted, rather cat-like mewing "rr'raow-...rr'raow..." (first note short and descending, second note longer, rising, with slight downward inflection at end, and emphasized), with intervals of 2–3 seconds between each call.

**Habitat.** Understorey and bamboo in primary upper montane broadleaf evergreen forest (canopy height 10–15 m), at 2000–2200 m. **Food and Feeding.** No information on diet; probably invertebrates from leaf litter. So far noted only singly or in pairs; has been seen to associate with *T. mitnei*. **Breeding.** Male with gonads enlarged in May. No other information.

**Movements.** Resident.

**Status and Conservation.** VULNERABLE. Restricted-range species: present in Kontum Plateau Secondary Area (which now becomes a full EBA with discovery also of *Actinodura sodangorum*). Uncommon and local. Currently known only from Mt Ngoc Linh and Mt Ngoc Boe, on Kontum Plateau of C Vietnam, and inferred therefore to have a very small global range (estimated at 155 km<sup>2</sup>), but likely to occur also in neighbouring Attapu and Se Kong provinces of SE Laos. Population unknown. On Mt Ngoc Linh, known from Ngoc Linh Nature Reserve (Kontum province) and Ngoc Linh Proposed Nature Reserve (Quang Nam province). At former locality 13% of broadleaf evergreen forest was lost during 1976–1995, and forest at latter site is threatened by clearance for agriculture, a process that is accelerating in response to natural population growth and settlement of migrants in area.

**Bibliography.** Anon. (2006d), Butchart & Stattersfield (2004), Collar (2006), Collar *et al.* (2001), Eames (2001), Eames, Lê Trong Trại & Nguyễn Cu (1999), Nguyễn Cu *et al.* (2000), Robson (2000), Stattersfield & Capper (2000), Tordoff *et al.* (2000).

## 261. Collared Laughingthrush

### *Trochalopteron yersini*

**French:** Garrulaxe de Yersin **German:** Halsbandhäherling **Spanish:** Charlatán de Yersin

**Other common names:** Yersin's Laughingthrush

**Taxonomy.** *Trochalopteron yersini* Robinson and Kloss, 1919, Lang Bian Peaks, southern Annam, Vietnam.

Genus traditionally subsumed in *Garrulax*. Monotypic.

**Distribution.** S Annam, in Vietnam.

**Descriptive notes.** 26–28 cm. Strikingly patterned medium-sized laughingthrush with black hood, silvery-grey ear-coverts, bright rufous underparts and hindcollar, and golden-olive wing fringing. Has bristly lores, superciliary area, crown, nape, area behind ear-coverts, chin and throat black, postocular area and ear-coverts shiny silvery grey with vague blackish streaks; nape and upper mantle, neck side, breast, upper flanks and belly bright rufous, shading to ochrous dark grey on remaining upperparts (including median wing-coverts), and to ochrous dark brown on lower flanks, thighs and vent, greater upperwing-coverts rufous-chestnut, primary coverts black, flight-feathers ochrous dark grey with outer fringes semi-reflective grey-tinged golden-olive, tail ochrous dark grey with grey-tinged golden-olive on outer fringes of feathers; iris crimson, brown or hazel; bill black; legs dark brown. Sexes similar. Juvenile is patterned as adult, but chestnut areas paler and browner, grey of back replaced by purplish-brown. Voice. Song a loud, quite high-pitched, rising whistle repeated every 3–5 seconds, typically "wueeeoo" or "u-weeeoo" (rising in middle), "uuuu-weeoo" (rising more at start), "wiu-weeeu" (quick first note, stressed second note), or "wu-eyou" (rising sharply at end); variants include "weeoo-wiu", "yiuuuu-ee", "wuuuu-ip" and "wuuuu-oo" (last two heard in duet), sometimes a shorter "u-weeaa". Two or three birds may sing to each other. Whistles often answered antiphonally (presumably by females) with low, quite harsh, mewing "vaaaah", "ayaaa" or "ohaaaah" (these calls sometimes uttered on their own); short, breathless "phu" may also be given antiphonally with whistles. Alarm call a series of variable, subdued, slurred, buzzy, grating, slightly rising notes, "greet-greet-greet-greet-greet-greet-greet-greet-grrr-rr" (with last 3 or so notes slurred together).

**Habitat.** Understorey (usually rather dense) of primary broadleaf evergreen forest, thick regrowth in logged-over forest, scrub bordering forest; at 1500–2440 m.

**Food and Feeding.** No information on diet. Found in pairs or in small parties of up to eight individuals; relatively retiring. Forages low down in dense vegetation and on ground.

**Breeding.** Juveniles in Apr and Jun, suggesting breeding probably mainly Mar–May. No other information.

**Movements.** Resident.

**Status and Conservation.** ENDANGERED. Restricted-range species: present in Da Lat Plateau EBA. Locally common in suitable habitat within its altitudinal range. Population estimated at 2500–9999 individuals and decreasing; occupied range estimated as being merely 720 km<sup>2</sup>. Recorded from at least eleven localities, with post-1980 records from eight, the most important appearing to be Mt Lang Bian, Mt Hi Doup and Chu Yang Sin Nature Reserve. Da Lat Plateau currently focus for a government resettlement programme, resulting in forest degradation and fragmentation through logging, shifting agriculture, fuelwood-collecting and charcoal production; this species, however, generally occurs at elevations rather higher than those where shifting cultivation currently practised. On Mt Lang Bian, all land below 1500 m is now logged or under cultivation. Species is present in Thuong Da Nhim Nature Reserve.

**Bibliography.** Anon. (2004d), Berlioz (1930), Butchart & Stattersfield (2004), Collar *et al.* (2001), Delacour & Jabouille (1931a), Eames (1995), Eames & Ericson (1996), Eames *et al.* (1992), Hill *et al.* (2001), Nguyễn Cu *et al.* (2000), Robinson & Kloss (1919a), Robson (2000), Robson *et al.* (1993a, 1993b), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

**262. Red-winged Laughingthrush***Trochalopteron formosum*

**French:** Garrulaxe élégant **German:** Prachthäherling **Spanish:** Charlatán Alirrojo  
**Other common names:** Crimson-winged Laughingthrush

**Taxonomy.** *Trochalopteron formosum* J. Verreaux, 1869, “le Thibet oriental” = western Sichuan, China. Genus traditionally subsumed in *Garrulax*. Individuals of this species observed in N Guangxi of unknown race; presumably belong with nominate. Two subspecies recognized.

**Subspecies and Distribution.**

*T. f. formosum* J. Verreaux, 1869 – N & C Sichuan and extreme NE Yunnan, and N Guangxi, in SC & S China.

*T. f. greenwayi* (Delacour & Jabouille, 1930) – S China (SE Yunnan) and N Vietnam (W Tonkin).

**Descriptive notes.** 27–28 cm; 83–106 g. Fairly large, dull rufous-brown laughingthrush with silvery grey and black on head and crimson fringing on wings and uppertail; crown feathers elongate and pointed. Nominat race has crown feathers blackish with broad silvery-grey edges (forming uneven streaks), shading to dull darkish rufous-brown on nape, neck side, scapulars and back, rump darker and more olive; upperwing blackish-brown with crimson primary coverts and broad fringing, tail crimson centrally, outer rectrices crimson on outer webs and blackish-brown on inner ones; bristles lores black, black extending over eye

in vague supercilium and continuing around ear-coverts, ear-coverts blackish with broad silvery-grey streaks, submoustachial area blackish with indistinct silver-grey flecks; chin, throat, lower neck side and breast matt black, becoming slightly scaly on lower breast, with transition to dull darkish rufous-brown on belly, which itself becomes more olive and then sootier towards vent; iris brown; bill black; legs dark brown to dark grey. Distinguished from similar *T. milnei* mainly by lack of chestnut crown and lack of whitish ear-coverts. Sexes similar. Juvenile is like adult. Race *greenwayi* is dull olive where nominate dull rufous-brown, has breast less extensively black, more dark-scaled with silvery edges. Voice. Song consists of repeated loud, rather thin, clear whistled phrases, “chu-weewu” or slightly rising “chiu-wee”. Possible duets (perhaps intra-sex) include “chiu-wee—u-weewoo” (second part rising slightly in middle) and “u-weewoo—wueewoo” (second part quickly delivered). Also a louder “wu-ecoo”.

**Habitat.** Broadleaf evergreen forest, secondary growth and scrub near forest, including prickly oak (*Quercus*), and bamboo; at 900–3150 m, but in Vietnam not recorded below 2400 m.

**Food and Feeding.** No information on diet; presumably invertebrates and some vegetable matter. Usually forages in pairs or small parties, on or close to ground; also ascends to 4–5 m in small trees. Shy and skulking.

**Breeding.** Jun–Jul. Young fed by both sexes. No other information.

**Movements.** Resident. Irregular, minor, local altitudinal movements, particularly during heavy snowfall, considered possible.

**Status and Conservation.** Not globally threatened. Formerly considered Near-threatened. Restricted-range species: present in Central Sichuan Mountains EBA and Fan Si Pan and Northern Laos Secondary Area. Rare in China, but fairly common at Emei Shan Protected Scenic Area, in Sichuan. Scarce at high levels in Fan Si Pan National Park, in Vietnam.

**Bibliography.** Berlioz (1930), Cheng Tsohsin (1987), Cheng Tsohsin *et al.* (1963), Delacour & Jabouille (1930, 1931a), Dowell *et al.* (1997), Huang Qiang *et al.* (1995), King (1989a), Lee Kwok Shing *et al.* (2006), Li Guiyuan, Liu Liangcai *et al.* (1976), Li Guiyuan, Zhang Qingmao *et al.* (1994), Lieberman (1984), Meyer de Schauensee (1984), Robson (2000), Stattersfield *et al.* (1998), Stresemann (1923c), Zhang Quntian *et al.* (1994).

**263. Red-tailed Laughingthrush***Trochalopteron milnei*

**French:** Garrulaxe à queue rouge **German:** Rotschwanzhäherling **Spanish:** Charlatán Colirrojo

**Taxonomy.** *Trochalopteron Milnei* David, 1874, western Fujian, China.

Genus traditionally subsumed in *Garrulax*. Population in C highlands of Vietnam (C Annam) and presumably adjacent SE Laos probably represents an undescribed race, or possibly belongs with *viryi*. Four subspecies recognized.

**Subspecies and Distribution.**

*T. m. sharpei* Rippon, 1901 – N & E Myanmar, NW Thailand, N & C Laos, NW Vietnam, and S China (W, S & SE Yunnan, W Guangxi).

*T. m. sinianum* Stresemann, 1930 – SE China (SE Sichuan, N Guizhou, C & NE Guangxi, S Hunan, N Guangdong).

*T. m. milnei* David, 1874 – NW Fujian, in SE China.

*T. m. viryi* (Delacour, 1932) – S Laos (Bolovens Plateau).

**Descriptive notes.** 26–28 cm; 66–93 g. Medium-sized dull ochrous-grey laughingthrush with bright rufous-chestnut crown, blackish face, whitish ear-coverts and crimson wings and tail. Nominat race has crown to nape bright rufous-chestnut, shading abruptly to ochre-stained mid-grey neck side, mantle and back with wide dark scaling, darker and plainer ochrous on rump and uppertail-coverts; upperwing fringes extensively crimson, tail duller greyish-crimson; face (lores to above eye and upper submoustachial area) blackish, ear-coverts whitish; chin and upper throat blackish, shading to grey-scaled olive on lower

throat and breast and plain greyish-olive on lower underparts; iris crimson to hazel or dark brown, orbital skin grey; bill black; legs black or dark purplish-grey. Sexes similar. Juvenile is like adult. Race *sharpei* is like nominate, but ear-coverts silvery; *sinianum* is slightly paler-crowned, more silvery-eared and blacker-throated, with breast and underparts much greyer; *viryi* is like last, but breast extensively scaled blackish, birds in C Annam and adjacent S Laos having paler throat and breast with more pronounced scalloping. Voice. Sings with clear loud whistled phrases, e.g. “uuu-weewoo”, “eeoo-wee” or shorter “uuuwi” (all rising at start), or “uuuu-hiu-hiu” and “uuuu-hiu-hiu-hiu”, with slightly rising introduction and faster, soft laughter at end.

**Habitat.** Understorey of broadleaf evergreen forest (including dry degraded tracts), dense secondary growth, bamboo forest and patches, cane-brakes, scrub and grass near forest, at 610–2500 m (mainly above 900 m). Seen in scrub in Thailand; in Laos only in hill evergreen forest (including where *Fokienia* dominant), although not in forest isolates.

**Food and Feeding.** Insects, including beetles (Coleoptera), also small centipedes (Chilopoda); also berries and fruits of *Saurauja* (Theaceae). Forages in pairs or in small parties of 2–4 individuals, rarely quite large parties; usually 2–5 m above ground, sometimes lower, or on ground itself. Often very skulking in dense vegetation.

**Breeding.** Apr–Jun. Nest, constructed by both adults, a tidy cup made of bamboo leaves and grasses, lined with roots, placed up to 1 m above ground in bush or against side of tree. Clutch 2–3 eggs, white, sparingly spotted and blotched with dark red, reddish-brown or blackish, sometimes with a few purplish undermarkings; in captivity, incubation period 17–18 days and nestling period 14–16 days; nestlings fed by both parents.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Nominat race apparently rather uncommon and restricted in range, and species in general considered local and uncommon to rare in China; recently recorded in Diding Nature Reserve, in Guangxi, but at best uncommon there. Scarce to uncommon in SE Asian part of range. In Laos, historically common on Bolovens Plateau above 800 m but very rare in Tranninh; currently common in Dong Hua Sao National Biodiversity Conservation Area (NBCA) above 1100 m, present (common above 1000 m) in Nakai-Nam Theun NBCA, and present and probably common in Xe Sap proposed protected area. In Vietnam, locally common in Fan Si Pan National Park and present in Na Hang and Vu Quang Nature Reserves.

**Bibliography.** Anon. (2004c), Berlioz (1930), Caldwell & Caldwell (1931), Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paolai (1960), David-Beaulieu (1944), Davidson (1998), Deignan (1963), Delacour & Jabouille (1931a), Dickinson (1970), Eames *et al.* (2001), Engelbach (1932), Evans & Timmins (1998), Haines (1989), Harrington (1909, 1914a), Hill (2000), La Touche (1899, 1925–1930), Lê Manh Hùng *et al.* (2002), Lee Kwok Shing *et al.* (2006), Lekagul & Round (1991), Lewthwaite (1996), Liu Kezhi *et al.* (1994), McLeod (1996), Meyer de Schauensee (1934, 1946, 1984), Oldenettel (1989a), Robbins *et al.* (2006), Robson (2000), Showler, Davidson, Chanthavi Vongkhamheng & Khounmee Salivong (1998), Smythies (1940, 1949), Stanford & Mayr (1941), Stanford & Tiechurst (1938), Thewlis, Duckworth *et al.* (1996), Thewlis, Timmins *et al.* (1998), Timmins & Wilkinson (1996), Tordoff, Lê Manh Hùng *et al.* (2002), Tordoff, Lê Trong Dat *et al.* (2001), Uchida & Kuroda (1916), Wang Zhijun & Wei Tianhao (1983), Wickham (1929), Wu Zhikang *et al.* (1986).

## PLATE 19

## Family TIMALIIDAE (BABBLERS) SPECIES ACCOUNTS

### Genus *LIOCICHLA* Swinhoe, 1877

#### 264. Crimson-faced Liocichla

##### *Liocichla phoenicea*

French: Garrulaxe à ailes rouges

Spanish: Charlatán Carirrojo

German: Sikkim-Karminflügelhäherling

Other common names: Red-faced Liocichla, Crimson-winged Laughingthrush

**Taxonomy.** *Ianthocinclia phoenicea* Gould, 1837, Nepal.

Has been treated in expanded genus *Garrulax*, but placement in present genus supported by recent molecular studies. Often treated as conspecific with *L. ripponi*. No definite records from Nepal, despite type-locality restriction (although "Nepal" specimens exist). Individuals at Gongshan, in NW Yunnan (China), of uncertain race, presumed to belong with nominate. Two subspecies recognized.

##### Subspecies and Distribution

*L. p. phoenicea* (Gould, 1837) - Sikkim and N West Bengal E to Bhutan and NE India (Arunachal Pradesh) and adjacent N Myanmar and S China (Gongshan, in extreme NW Yunnan).

*L. p. bakeri* (I. J. O. Hartert, 1908) - Meghalaya, S Assam (N Cachar), Nagaland, Manipur and Mizoram, in NE India, N Myanmar (W & S parts) and adjacent S China (W Yunnan).

**Descriptive notes.** 21–23 cm; 42–53 g. Fairly small laughingthrush-like babbler, mostly plain brown but with crimson face and throat, pale, bold black lateral cross-stripe and scarlet in wings and tail. Nominative race has crown and upperparts olive-brown, rufescent tinge posteriorly becoming chestnut on upperparts, coverts, upperparts, complex in coloration, with chestnut greater coverts and outer fringes of secondaries and tertials, primaries with scarlet fringes, secondaries pale-tipped and with narrow, pale grey outer edges basally and scarlet edges distally. Ilii blackish with broad tips dull ochraceous, tertiaries dark crimson, lateral crown-stripe black, face (supraorbital area, area around most of eye, postocular superciliary area and ear-coverts) and neck side crimson; chin

to flanks and thighs ochraceous olive-brown, with mid-grey belly and scarlet-tipped black undertail-coverts; iris crimson or dark crimson to reddish-brown, orbital skin dull lead-grey; bill dark brown to black; legs horn to brown. Sexes similar. Juvenile has duller face than adult, upperparts less rufous, lateral crown-stripe less distinct, rufescent tail tip less sharply defined, iris brown. Race *bakeri* has slightly greyer crown than nominate, slightly darker and less extensive red on head, little rufous or chestnut tinge on rear upperparts, slightly paler and browner underparts, extensive grey on centre of abdomen. Voice: Has

loud, beautiful, clear, cheerful song of repeated phrases of 5–8 notes (sometimes shortened to 3), last part usually rising but sometimes falling. Phrases include e.g. "che-wi-ter-twi-twitoo", "chi-cho-choe-wi-chu-choe", "chi-wee-ee-wee-wee" and "chi-cho-ee" etc. Songs of nominate race described also as "tyu, tiyuu, tyuu, fwhee-tyu" (slightly downslurred, except penultimate note), "tee, tyu-tuu, ti-tuu-fwheee" (end note richer, more strongly upslurred), and "tutui-tui-twee-tyuu"; those of *bakeri* as more deeply slurred "tui-tui-fwée-tyuu" and "tyu-fwée-tyu f66-tiwi". Calls with harsh grating rasping notes, e.g. "chrrrt-chrrrt" and buzzy, upslurred grumbling "grsh! grsh!".

**Habitat.** Dense undergrowth in broadleaf evergreen forest, dense thickets of secondary growth bordering cultivation and streams, grass, scrub; in Bhutan appears to require large areas of intact broadleaf forest (no records from more fragmented tracts). At 500–2500 m (chiefly 1200–2000 m), mainly above 900 m.

**Food and Feeding.** Insects, berries and seeds. Usually found singly, in pairs or in small groups of 4–5 individuals, depending on season (small flocks of up to five usually found only from Jul in Bhutan); sometimes associates with other species in bird waves. Very skulking and unobtrusive. Typically feeds in undergrowth and on ground, sometimes in open. Occasionally ventures into trees, and has been observed 10 m up in fruiting tree.

**Habitat.** Inhabits undergrowth of secondary broadleaf evergreen forest, dense young secondary growth, scrub and grass, bamboo thickets, replanted forest, and dense vegetation in more open forest; appears to prefer early successional habitats. Present at 600–2400 m; perhaps commonest at 1700–2200 m.

**Food and Feeding.** Fruit and invertebrates. Occurs singly, in pairs or in small family groups. Rather skulking, though not particularly shy. Forages in low thick vegetation up to 4 m above ground.

**Reproduction.** May–Jun; in captivity multi-brooded. Nest a robust cup with untidy base, made of moss, small twigs, dead bamboo and other leaves, grass stems, and roots, lined with fine dead grasses and roots, and woven around several fine dead bamboo shoots, completely shielded from above by row of bamboo leaves, or placed in bush 0.3–1 m above ground. Clutch 3–4 eggs, pale sky-blue to bright blue, irregularly marked with long reddish-brown to dark red-brown squiggles, lines and spots. In captivity: incubation probably by both sexes, period 13 days from final egg laid; nestling period 12–15 days.

**Movements.** Resident or partial elevational migrant; all records during summer are from above 1000 m, and once found at 600 m in Jan.

**Status and Conservation.** VULNERABLE. CITES II. Restricted-range species: present in Chinese Subtropical Forests EBA. Known from at least 14 sites in Sichuan and two in Yunnan. Locally common at Emei Shan Protected Scenic Area (a sacred mountain and therefore subject to only limited forest clearance) and in Xiaoxiang Ling and Daliang Shan range; in one study a mean density of 0.596 birds/ha was estimated, with 0.9 birds/ha in secondary forest and 0.502 birds/ha in primary forest; recorded also in Mabian Dafengding Nature Reserve. Is generally, however, highly localized within small range, suggesting that total population is small and probably declining. Although not a primary-forest species and probably thrives in secondary habitats, main threat is loss and fragmentation of suitable habitat, much of which has already been cleared or degraded, through logging and conversion to agriculture. Trapping for export as cagebirds may also be a minor threat, although this is a protected species in Sichuan. Since 1999, the export of wild birds from China has been banned, but law may be difficult to enforce.

**Bibliography.** Anon. (2006d), Butchart & Stattersfield (2004), Cheng Tsohsin (1987), Cheng Tsohsin *et al.* (1963), Collar *et al.* (2001), Delacour (1933), Dowell *et al.* (1997), Huang Qiang *et al.* (1995), Meyer de Schauensee (1984), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

## 268. Taiwan Liocichla

### *Liocichla steerii*

**French:** Garrulaxe de Steere **German:** Formosahäherling **Spanish:** Charlatán de Steere  
**Other common names:** Steere's Liocichla/Babbler

**Taxonomy.** *Liocichla steerii* Swinhoe, 1877, mountains of southern Taiwan.

Closely related to *L. omeiensis*, and in the past often treated as conspecific with it; these two and *L. hugunorum* may form a superspecies. Monotypic.

**Distribution.** Taiwan.

**Descriptive notes.** 17–19 cm; mean 32 g. Small, small-billed, green-and-grey laughing-thrush-like babbler with bright yellow loreal patch, black brow and rufous wing patch. Male has forehead olive-yellow, crown dark slate, becoming blackish laterally over eye (extending to frontal supercilium) and merging on mantle into greyish-olive, warmer and browner on scapulars, greyer on rump; tail warm greyish-olive with broad slate-grey subterminal marks and narrow whitish tips; flight-feathers fringed yellowish-olive, with black ends and narrow white tips, tertials bright rufous on outer webs; lores to anterior cheek bright yellow.

low or sometimes orange-yellow (forming distinctive downslanting oblong preocular patch), narrow yellow postocular supercilium breaking up into elongate flecks on neck side; ear-coverts, hindcheek and submoustachial area brownish-olive, malar area and chin to breast slaty grey; breast and mid-belly yellow-olive, flanks, lower belly and thighs slaty grey with whitish tinges, undertail-coverts blackish with yellow tips; undertail yellowish-olive; iris dark brown, narrow orbital skin pale bluish-grey; bill blackish-brown; legs flesh-brown. Female closely resembles male but slightly smaller, with smaller yellow loreal patch. Juvenile apparently undescribed. Voice. Vocalizations divided into nine types. Song (male territorial call) a high-pitched rapid "tssi, ti'wuu" or "tswi, ti'wuu" (short sharp introductory note, longer and slightly quavering "wuu"), typically repeated every 5–8 seconds; female response to this a slower, buzzy chirp, so that due transcribed as "hui-dididu dddzddz" or "swiya-swiya jrzz-jrzz-jrzz"; male song variable, sometimes with more syllables, variation tends to follow geographical pattern (some populations generally using a given number of syllables, others another). Other calls comprise two types of alarm call, also fighting call, escape call, distress call, social call and chick begging call; one of these (probably an alarm, as conversational excitement) is a conversational buzzy rasping, of varying lengths and strengths, "djrrr... djrrr... djrrr... djrrr...".

**Habitat.** Broadleaf evergreen forest and mixed broadleaf-coniferous forest, forest edge, tangled shrubbery, and orchards, at 1200–3000 m; in N Taiwan, elevational limits 830–2780 m.

**Food and Feeding.** Insects, including grasshoppers (Orthoptera); worms; also small fruits, berries and seeds. In winter, may rely heavily on food discarded by tourists at certain sites, and recorded even as feeding on remains of dead conspecifics. Forages in low vegetation, typically below 2 m on plants less than 4 m tall, and on shaded damp ground. Not particularly shy. Typically occurs singly, in pairs, or in small groups; occasionally joins bird waves.

**Breeding.** Mid-Mar to mid-Aug/Sept. Nest a cup made of bamboo leaves, moss, bark, roots and dead leaves, lined with fine grass, fine roots, grass-stems and plant fibres, placed in bush or small tree up to 5 m above ground, height apparently depending on abundance of *Miscanthus* grass; mean territory size 0.6 ha. Clutch 2–4 eggs (average 2.5), pale milky blue or green, marked all over with brown blotches and long twisted lines, and with greyish-purple underblotches; incubation by both sexes, only female at night, period 16 days; chicks brooded by both parents for 8 days, also fed by both, nestling period 12 days.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Taiwan EBA. Frequent to very common throughout elevational range. In Yushan National Park, recorded densities of 1.83 birds/ha in mixed coniferous forest and 2.18/ha in spruce forest, although these not preferred habitats. Apparently a pest in cultivated millet (*Pennisetum glaucum*), potato, peach and orange crops.

**Bibliography.** Cheng Tsohsin (1987), Collar *et al.* (2003), Ding Tzungsu *et al.* (1997), Hachisuka & Udagawa (1950, 1951), Kirchhofer (1986, 1994), Koh Chaonien & Lee Peifen (2003), Luo Liuchi (1987), Mays *et al.* (2006), Meyer de Schauensee (1984), Severinghaus & Blackshaw (1976), Smith & Yu Hontsen (1992), Stattersfield *et al.* (1998), Yen Chungwei (1990).

## Genus *CHRYSOMINLA* Wolters, 1980

### 269. Bar-throated Minla

#### *Chrysominla strigula*

**French:** Minla à gorge striée **German:** Bändersiva **Spanish:** Minla Colicastaña  
**Other common names:** Bar-throated Siva, Chestnut-tailed/Stripe-throated Minla

**Taxonomy.** [*Mesia*] *Siva strigula* Hodgson, 1837, Nepal.

Commonly placed in genus *Minla*. Proposed races *victoriae* (from Mt Victoria, in W Myanmar) and *cinereigenae* (Meghalaya E to SW Nagaland, in NE India) synonymized with *yunnanensis*. Six subspecies recognized.

**Subspecies and Distribution.**

*C. s. simlaensis* (R. Meinertzhagen, 1926) – N India (W Himachal Pradesh) E to W Nepal.

*C. s. strigula* (Hodgson, 1837) – WC Nepal E to Bhutan and NE India (W Arunachal Pradesh) and adjacent S China (S Xizang).

*C. s. yunnanensis* (Rothschild, 1921) – NE Indian hill states, adjacent S China (SE Xizang, Yunnan and SW Sichuan), N, NE & W Myanmar, N & C Laos and N Vietnam (Tonkin).

*C. s. castanicauda* (Hume, 1877) – SE Myanmar (including N Tenasserim) and NW & W Thailand.

*C. s. malayana* (E. J. O. Hartert, 1902) – Peninsular Malaysia.

*C. s. traili* (J. C. Eames, 2002) – C Vietnam.

**Descriptive notes.** 16–18.5 cm; 14–24 g. Small grey to yellow babbler with ragged yellowish-rufous crown, barred throat, colourful wings and chestnut-edged black tail. Nominative race has loose-feathered crown yellowish-rufous, upperparts olive-grey; black primary coverts, contrasting orange-yellow and black flight-feather fringes and broadly whitish-bordered tertials; tail dull brownish-chestnut and black, with broad whitish outer tips and yellow fringe; short narrow dusky supercilium, blackish-tinged yellow lores and ear-coverts, black submoustachial stripe extending under ear-coverts; chin yellow, throat whitish with wavy black bars, underparts pale yellowish; iris brown to bright red; bill greyish-brown to black, paler below; legs brownish-grey to bluish-grey. Sexes similar. Juvenile is greyer above than adult, more washed out below, with narrower and more broken throat bars. Race *simlaensis* has chestnut on tail confined to basal half; *yunnanensis* is more slaty olive above, yellower on crown and belly, chestnut of tail darker and extending much closer to tip; *castanicauda* is like previous, but blacker ear-coverts, much paler, more washed-out chestnut on tail; *malayana* has more slate-grey ear-coverts, greyish-olive wash on breast and flanks; *traili* has mostly whitish lores, cheek and upper ear-coverts, brighter crown and greyer upperparts. Voice. Sings with high-pitched, slightly quavering "tui-tui-tu", "tui ti-u" or "tui-tui-tui-tui", with higher third note, repeated every few seconds; songs described also as sweet, clear, rising, deliberately paced "syuwéet-suéet-séet" (first part downslurred and then upslurred, second part less slurred, final note highest and unslurred), and a sweet, lisping, falling "p'séet-páséet-pásuú" (notes steeply downslurred, last slightly longer and lowest). Calls include sharp "kip" and softer, nasal "yeeep" notes, weak fussing notes, then upward buzz and louder trilling buzz, e.g. "chipitchip-dzwipitidjéééééééééé" (end note strongly downslurred, with jeering quality) given intermittently with song phrases.

**Habitat.** Broadleaf evergreen forest (especially oak), mixed broadleaf-conifer forest, subalpine oak and rhododendron forest, sometimes pine forest, mixed pine-rhododendron; open forest of birch (*Betula*), willow (*Salix*), barberry (*Berberis*), bushes in forest, oak and rhododendron scrub or other low bushes, bamboo. At 1800–3750 m (1600–3000 m in SE Asia); locally as low as 1300 m during harsh winters in Indian Subcontinent; in Bhutan 2000–3400 m in summer in cool broadleaf, fir and hemlock forests, 1800–3200 m in winter in cool broadleaf forest and adjacent scrub-forest.

**Food and Feeding.** Beetles (Coleoptera), caterpillars and other insects; also berries and seeds, including those of the small myrtaceous tree *Baeckia frutescens*; also nectar from rhododendron flowers. Almost exclusively insectivorous in summer. Arboreal, feeding in tree-tops as well as low herbage; takes insects from rhododendron flowers. Outside breeding season in parties of 6–20 individuals; often joins bird waves, which frequently include other babblers such as *Minla ignotincta* and yuhinas.

**Breeding.** Mar–Aug. Nest a neat cup made of grass, bamboo leaves, moss, black fibrous and other roots, birch bark, pieces of bamboo strippings and thread-like *Usnea* lichen, lined with hair, rootlets, pine needles and fern stalks, placed 1.5–3 m above ground in bush or small tree. Clutch 2–4 eggs (usually 3 in India), bright pale blue, deep blue or blue-green to turquoise, lightly spotted or freckled with black or pale red or brown. No other information.

**Movements.** Resident; some local, rather slight seasonal altitudinal displacements. Claimed status as winter immigrant into Nagaland (NE India) requires substantiation.

**Status and Conservation.** Not globally threatened. Common in Nepal, including Langtang National Park. Common in temperate zone in Bhutan, and present in Thrumshingla National Park. Fairly common in W part of Indian range, common in E; uncommon in Dehra Dun valley and present in Nanda Devi Biosphere Reserve (both in Uttaranchal), present in Buxa Tiger Reserve (West Bengal) and present in and/or near Eaglenest Wildlife Sanctuary (Arunachal Pradesh). Abundant in Natmantaung (Mt Victoria) National Park, in Myanmar. Common in China. Generally locally common to common in SE Asian range. In Laos, very common above 1800 m on Phou Laoko, in Nakai-Nam Theun National Biodiversity Conservation Area. Present in Vu Quang Nature Reserve, in Vietnam.

**Bibliography.** Ali & Ripley (1948, 1971), Ali *et al.* (1996), Allen *et al.* (1997), Bingham (1903), Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paolai (1960), Choudhury (2001, 2003), David-Beaulieu (1944), Davidson (1998), Deignan (1963), Delacour & Jabouille (1931a), Dowell *et al.* (1997), Eames (2002), Eames *et al.* (2001), Evans & Timmins (1998), Gaston *et al.* (1994), Greenway (1933), Hume & Davidson (1878), Inskipp & Inskipp (1991, 1993b), Inskipp *et al.* (2000), Katti *et al.* (1992), King *et al.* (2001), Lekagul & Round (1991), Ludlow (1951), Ludlow & Kinnear (1937, 1944), Mariens & Lee (1995), Medway & Wells (1970, 1976), Meyer de Schauensee

whitish fringing on wings and tail. Juvenile is like female, but mantle slightly darker and white plumage parts duller, with faint dark scales below. *Race mariae* is olive-brownish (instead of maroon-brown) above, brighter yellow below; *jerdoni* has underparts weaker yellow, more grey-tinted; *sini* is greyer above, more heavily streaked greyish on flanks, bill longer. Voice. Song a fairly high-pitched, loudish, quite quickly repeated (every few seconds) "wi ti wi-wu" (first 2 notes higher); or strident, hurried, slurred, falling "si-swée-swéeéúúú" (first note highest, last prolonged and downslurred). Calls with subdued harsh "wih-wih-wih-wih...", louder, harsher "yih-yih-yih-yih", short "wit" and "wih" notes, and hurried "witti-wi-wrrh".

**Food and Feeding.** Chiefly insects and their larvae; also seeds. Usually found in parties, sometimes of considerable size; often joins bird waves, which may contain other habbblers, such as *Chrysomitris strigula* and yuhinas. Methodically searches branches and trunks, in manner of a treecreeper (*Certhia*), inspecting moss and lichen. Hops along horizontal branches, bending from side to side to inspect undersurfaces.

**Movements.** Resident; seasonal altitudinal displacements described for Bhutan.

**Status and Conservation.** Not globally threatened. Frequent in W of range in Nepal, becoming fairly common in E; common in Langtang National Park. Common in temperate zone and foothills in Bhutan, but relatively scarce in W valleys; present in Thrumshingla National Park. Locally fairly common in India, where present in Buxa Tiger Reserve (West Bengal) and in Eaglenest Wildlife Sanctuary and Namdapha and Mouling National Parks (all Arunachal Pradesh). Formerly resident in Bangladesh, but no recent records. Common in Natmataung National Park, in Myanmar. Common in S China, but recently recorded only in Maershan and Cenwangaolaan Nature Reserves, in Guangxi, and not found at 52 other sites surveyed. Generally common in most of SE Asian range. Common in Nakai-Nam Theun National Biodiversity Conservation Area, in Laos. Common in Fan Si Pan National Park and present in Pu Mat and Vu Quang Nature Reserves, in Vietnam.

**Bibliography.** Ali & Ripley (1971), Ali *et al.* (1996), Allen *et al.* (1997), Bangs & Van Tyne (1931), Betts (1956), Birand & Pawar (2004), Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paoli (1960), Cheng Tsohsin *et al.* (1963), Choudhury (2003), Davidson (1998), Delacour & Jabouille (1931a), Dowell *et al.* (1997), Farnes *et al.* (2001), Evans & Timmins (1998), Gaston (1989), Grimmer *et al.* (1998), Huang Qiang, Deng Heli & Mao Ke (1995), Huang Qiang, Huang Yongzhao & Deng Heli (1993), Inskip & Inskip (1991, 1993b), Inskip *et al.* (2000), Katti *et al.* (1992), King (1989b), King & Han Lianxian (1991), King *et al.* (2001), La Touche (1923), Lee Kwok Shing *et al.* (2006), Lewthwaite (1996), Ludlow (1951), Ludlow & Kinnear (1937), Martens & Eck (1995), Meyer de Schauensee (1984), Rasmussen & Anderton (2005), Robson (1986, 2000), Rothschild (1926, 1960), Rowder (1999), Showler, Davidson, Chanthavi Vongkhamheng & Khounme Salivong (1998), Singh (1995), Smith *et al.* (1940, 1942), Smythies (1986), Spierenburg (2005), Stanford & Mayr (1941), Stanford & Ticehurst (1935, 1938), Stevens (1914, 1923), Stresemann (1923c), Stresemann & Heinrich (1940a), Stuart Baker (1893), Thet Zaw Naing (2003), Tordoff, Lei Man Hing *et al.* (2002), Tordoff, I & Trng Dat *et al.* (2001), Vogel *et al.* (2003), Wang Zhijun & Wei Tianhao (1983), Wu Zhikang *et al.* (1986), Yen Kwokyueng (1934a), Zheng Zuoxin *et al.* (1983).

of feathers; submoustachial and malar areas white, chin and throat yellowish-white, becoming pale yellow with vague long greyish streaks on underparts; iris pale yellow to cream, sometimes brown; bill blackish-brown, paler horn on lower mandible; legs olive-brown to yellowish-horn. Female has dorsal maroon-brown replaced by dull greyish-brown to olive-brown, paler pinkish-yellow to

# Genus *SIVA* Hodgson, 1837

## 271. Blue-winged Siva

### *Siva cyanouroptera*

**French:** Siva à ailes bleues **German:** Blauflügel-siva **Spanish:** Siva Aliazul  
**Other common names:** Blue-winged Minla

**Taxonomy.** *Siva cyanouroptera* Hodgson, 1837, Nepal. Often placed in genus *Minla*, but markedly different vocally from latter and no evidence for a close relationship. Probably fairly close to *Mesia* and *Leiothrix*. Race *orientalis* fairly distinctive; taxonomic status requires further evaluation. Proposed race *croizati* (from Sichuan, in SC China) treated as a synonym of *wingatei*. Seven subspecies recognized.

#### Subspecies and Distribution.

*S. c. cyanouroptera* Hodgson, 1837 – E Uttaranchal Pradesh E to Bhutan, all NE Indian hill states and NW Myanmar.

*S. c. aglae* Deignan, 1942 – NE India (Mizoram) and W Myanmar (Chin Hills).

*S. c. wingatei* Ogilvie-Grant, 1900 – NE Myanmar, N Thailand, Laos, Vietnam (S to C Annam), S China (discontinuously NE, C & S Sichuan S to Yunnan, and SW Guizhou, Guangxi, S Hunan and Hainan).

*S. c. sordida* Hume, 1877 – SE Myanmar (including Tenasserim) and NW & W Thailand.

*S. c. sordidior* Sharpe, 1888 – S Thailand and Peninsular Malaysia.

*S. c. rufodorialis* Engelbach, 1946 – SE Thailand and SW Cambodia.

*S. c. orientalis* Robinson & Kloss, 1919 – S Vietnam (S Annam) and adjacent E Cambodia (Phumi Dak Dam, in S Monduliri).

**Descriptive notes.** 14–15.5 cm; 14–28 g. Rather small, slim, pale brownish babbler with longish tail, most races with bluish-black crown streaks and blue wing edges and tail. Male nominate race has crown to upper mantle soft pale grey, crown with long parallel blue-fringed blackish streaks, lower mantle, back, greater upperwing-coverts and scapulars to rump creamy buff-brown, primary coverts black with cobalt-blue fringes, edges of primaries cobalt-blue, tertials black with narrow white tips, tail black with narrow white fringes and cobalt-blue edges; face (lores, supercilium, cheek, ear-coverts) pale whitish-grey.

throat and underparts pale pinkish-grey with whiter belly and vent, lower flanks tinged buff; iris grey, greyish-brown, or dark hazel to whitish or yellowish-grey; bill yellowish-flesh to chrome-yellow, culmen brownish to dark horn; legs brownish to greyish-olive or fleshy white. Female is very similar to male, but has slightly less blue crown and paler mantle. Juvenile has browner, less streaked crown than adult. Race *aglae* has (sex for sex) slightly heavier-streaked crown than nominate; *wingatei* differs from previous in lacking white tips (trailing edges) on scapulars and tail; *sordida* has much-reduced crown streaks, duller upperparts and whiter underparts; *rufodorialis* has chestnut-brown crown and nape, crown with vague grey streaks, chestnut mantle and back and rufous upperpart-coverts, also richer blue on wings and tail; *sordidior* has browner crown and upperparts than other races, blue of wing darker, more violet, blue of tail reduced to vague tinge on outer fringes, whiter below; *orientalis* is larger than others, plumage as last but with paler grey-brown crown, greyer upperparts, and duller, almost entirely washed-out blue in wing, with whiter fringing on secondaries. Voice. Song a rather quickly repeated, very thin, high-pitched “psii si-suuu” or “sée-si-syáúú”, first 2 notes short and high (sometimes one or both are lacking), third greatly stressed and strongly downslurred (*aglae*): a rising and falling “tsuit-two” or “seet-siyúú”, first note longer and more upturned than in previous song type, last shorter but more strongly slurred, and a “suwéet-suwéé”, both notes strongly slurred (both *sordida*). Songs repeated every few seconds. Calls include irregular, short, dry staccato buzzes, and short “whit” and “bwik” contact notes.

**Habitat.** More open broadleaf evergreen, pine and mixed forests, forest edge, secondary growth, bamboo, cultivation near forest. In C Laos common also in *Fokienia*-dominated forest. Occurs at 250–3000 m, mainly c. 800–2600 m; in Bhutan 1600–2400 m, occasionally to 3000 m, some apparently descending as low as 200 m during harsh winter conditions.

**Food and Feeding.** Insects, berries and seeds. Usually found in parties of 5–20 individuals outside breeding season, and a frequent and conspicuous component of bird waves, which may include other babblers, such as minlas, cutias and sibias; in Assam (NE India), seen singly in association with mixed flocks. Forages in canopy, as well as in denser middle-storey growth, bushes and saplings, particularly along forest edge. Also comes closer to ground, especially when seeking certain fruits.

**Breeding.** Mar–Aug across range. Co-operative nest-building, involving three birds, noted in Peninsular Malaysia. Nest a fairly small cup, made of bamboo or other leaves, grass, rootlets, moss, tendrils and creeper stems (exterior often plastered with moss, cobweb and wool), lined with rootlets, fine grasses and sometimes hair, placed within 2 m of ground (usually below 1 m) in bush or streambank, occasionally up to 8 m above ground in tree (where may be suspended from fork or at extremity of branch). Clutch 2–5 eggs (3–4 in Indian Subcontinent, 2–4 in Myanmar), deep blue or bluish-white with a few small black or rusty-brown and violet spots; incubation period 14 days; nesting period in captivity 16 days.

**Movements.** Resident, perhaps with some local seasonal altitudinal displacements; in Bhutan reported descent occurs by Nov, ascent by mid-Apr. in NE India, described as regular winter migrant in Nameri National Park, in Assam, and winter immigrant in Nagaland.

**Status and Conservation.** Not globally threatened. Common in Nepal. Widespread in Bhutan, becoming steadily commoner farther E: near Zhengang, density of 1.2 territories/km of road at 1600–1900 m; present in Thrumshingla National Park. Common in India, where present in Buxa Tiger Reserve (West Bengal), in Nameri National Park (Assam), and in and/or near Eaglenest Wildlife Sanctuary (Arunachal Pradesh). Formerly resident in Bangladesh, but no recent records. Common in Natmataung National Park, in Myanmar. Common in S China, where recently re-

corded in six (11%) of 54 sites surveyed. Locally common in Hong Kong, where population of captive origin. Generally common in SE Asian range. In Laos, common in Dong Hua Sao National Biodiversity Conservation Area (NBCA) and, above 1400 m, in Nakai-Nam Theun NBCA. In Vietnam, present in Thuong Da Nhim and Chu Yang Sin Nature Reserves (Da Lat Plateau), in S Annam, and in Pu Mat and Vu Quang Nature Reserves in the Annamese Lowlands Endemic Bird Area.

# Genus *MESIA* Hodgson, 1837

## 272. Silver-eared Mesia

### *Mesia argenteauris*

**French:** Léiothrix à joues argent **German:** Silberohr-Sonnenvogel **Spanish:** Leiothrix Cariblanco  
**Other common names:** Silver-eared Leiothrix, Silver-ear

**Taxonomy.** [*Mesia*] *Mesia argenteauris* Hodgson, 1837, Nepal.

Probably fairly close to *Siva* and *Leiothrix*. Commonly placed in latter genus. Geographical variation considerable, and extremes of range very distinct: further study of species limits perhaps required. Races *vernayi* (NW Assam, N Myanmar and W Yunnan) and *aureigularis* (S Assam, W Myanmar) provisionally included in nominate. Seven subspecies recognized.

#### Subspecies and Distribution.

*M. a. argenteauris* Hodgson, 1837 – E Uttaranchal Pradesh E to Bhutan, NE Indian hill states, N & W Myanmar and adjacent S China (SE Xizang, W & NW Yunnan).

*M. a. galbana* Mayr & Greenway, 1938 – E & SE Myanmar (including Tenasserim) and N & W Thailand.

*M. a. ricketti* La Touche, 1923 – S China (S & SE Yunnan, S Guizhou, SW Guangxi), N & C Laos and N Vietnam (Tonkin and N Annam).

*M. a. cunhaci* Robinson & Kloss, 1919 – S Laos, Vietnam (C & S Annam) and adjacent E Cambodia.

*M. a. tahanensis* Yen Kwokying, 1934 – S Thailand and Peninsular Malaysia.

*M. a. rookmakeri* Junge, 1948 – N Sumatra.

*M. a. laurinae* (Salvadori, 1879) – Sumatra (except N).

**Descriptive notes.** 15.5–17 cm; 22–29 g. Smallish babbler in bright, neat colours, black on head with glistening silver ear-coverts, yellow breast, and red wing patch and tail base. Male nominate race has clear-cut jet-black crown to lores, forehead and upper submoustachial area, with orange-yellow patch on forehead above bill base, broadly fanned glistening silvery ear-coverts, dull orange-grey nuchal collar joining (around neck side) with bright yellow-orange chin to breast, and shading to grey on upperparts; upperwing with reddish patch at base of flight-feathers, latter fringed orange-yellow; black tail with narrow yellow

margins on outer webs, orange-reddish upperpart-coverts; duller yellowish-olive lower underparts; iris brown to crimson; bill orange-yellow; legs yellowish-flesh. Female has duller, paler forehead patch, throat and breast, dull golden-olive nuchal collar and upperpart-coverts, less yellow central underparts, pale yellowish-rufous underpart-coverts, paler and duller reddish wing patch and yellow wing fringing. Juvenile is like respective adult, but black of head duller, rest of body colours more washed out. Race *galbana* has greener upperparts than nominate, paler nuchal collar and underparts; *ricketti* has orange-red throat and upper breast, slightly darker underparts; *cunhaci* has much larger yellow forehead patch; *tahanensis* has peachier-toned breast and throat, whiter lower underparts with greyer flanks, slightly paler reddish wing patch; *laurinae* has, with orange-red tinge on forehead patch, orange-red chin to breast and neck side, dull reddish nuchal collar, with pale yellow iris, dark orange bill, orange legs; *rookmakeri* is like last but greener overall, with sharper demarcation between red nuchal collar and mantle. Voice. Song a repeated, cheerful, loud, clearly spaced, descending “che tchu-tchu che-rit” or “che chu chivi chwi”; described also as “tiwéet, tiwééet-tiréet-tiréet-tiwéééer” (most notes with upslurred end, and tightly constructed, with distinct breaks between them). Calls include flat piping “pe-pe-pe-pe-pe” (sometimes used to accompany song, perhaps by female) and harsh chattering notes.

**Habitat.** Bushes, undergrowth, lower and middle storeys in more open broadleaf evergreen, pine and mixed forests, forest edge, secondary growth, scrub, abandoned cultivation, tea plantations,

On following pages: 273. Red-billed Leiothrix (*Leiothrix lutea*); 274. Grey-crowned Crocias (*Crocias langbianis*); 275. Spotted Crocias (*Crocias albonotatus*); 276. Long-tailed Sibia (*Heterophasia picaoides*); 277. Rufous Sibia (*Malacias capistratus*); 278. Grey Sibia (*Malacias gracilis*); 279. Black-headed Sibia (*Malacias desgodinsi*); 280. Dark-backed Sibia (*Malacias melanoleucus*); 281. White-eared Sibia (*Malacias auricularis*); 282. Beautiful Sibia (*Malacias pulchellus*); 283. Rufous-backed Sibia (*Leioptila annectens*).

bamboo, sometimes other grassland; in Bhutan, key feature of habitat is natural openings in more extensive areas of intact forest that avoids degraded areas or extensive edge habitat. Occurs at 175–2100 m (probably mainly above c. 600 m); in Bhutan 600–1800 m, occasionally down to 300 m, and once at 2600 m.

**Food and Feeding.** Insects and their larvae, including ants (Formicidae); also berries, fruits and seeds, including those of cultivated maize (*Zea*). In Hong Kong study, in Aug–May, 87% of 30 faecal samples contained insects and 97% fruit (at least 14 plant taxa utilized). After breeding season forms parties of 5–30 or more individuals, often associating with bird waves (even during breeding season), which typically include other babblers. Usually keeps to bushes in more open forest, but sometimes ascends quite high, 4–5 m, in canopy. Occasionally makes flycatching sallies after escaping insects.

**Breeding.** Nov–Aug (from Apr in N areas); song in Bhutan Apr–Aug, with peak late Apr. Nest, built by both sexes over c. 4 days, a deep, substantial cup made of dead bamboo or other leaves, grass, moss, bracken and roots (including those of epiphytic plants), lined with rootlets or fern/palm fibres, placed from just above ground to up to 2 m above it in bush, slung from fine stems of small vines among branches of bushes or in bracken; said to be indistinguishable in size, structure and situation from that of *Leiothrix lutea*. Clutch 2–5 eggs (usually 4 in India, 2–3 in Peninsular Malaysia), white, lightly spotted with rich madder-brown (or identical to those of *Leiothrix lutea*); incubation, by both parents (female at night in captivity), from first egg, period 13–14 days; nestlings provisioned by both parents; in captivity, nestling period c. 12 days and post-fledging dependence c. 22 days.

**Movements.** Resident. Reported status as common winter visitor in Nameri National Park, in Assam (India), implies seasonal elevational movements, but substantiation required.

**Status and Conservation.** Not globally threatened. CITES II. Generally common in suitable habitat. Local in Nepal, rare in W to frequent in E. In Bhutan common but rather scattered throughout foothills and C & E valleys; near Zhenggang, density of 2.1 territories/km of road at 1600 m; present in Thrumshingla National Park. Formerly resident in Bangladesh, but no recent records. In India, fairly common E from Sikkim, rare in Dehra Dun valley (Uttaranchal); present in Buxa Tiger Reserve (West Bengal), where 15.9 birds/km<sup>2</sup> in semi-evergreen forest; present in (at least) Nameri National Park (Assam), and in Eaglenest Wildlife Sanctuary and Namdapha and Mouling National Parks (all Arunachal Pradesh). Common in China, although uncommon in Shiwandashan National Nature Reserve (Guangxi). Locally common in Hong Kong, where population of captive origin. Common in SE Asian range. In Laos, common in Dong Hua Sao National Biodiversity Conservation Area (NBCA) and in parts of Nakai-Nam Theun NBCA, and present in Phou Dendin NBCA. In Vietnam, common in Tam Dao National Park and present in Ba Be National Park and Na Hang Nature Reserve, and in Thuong Da Nhim and Chu Yang Sin Nature Reserves (Da Lat Plateau), in S Annam; also in Pu Mat Nature Reserve. Present in Gunung Leuser National Park, in Sumatra.

## Genus *LEIOTHRIX* Swainson, 1832

### 273. Red-billed Leiothrix

#### *Leiothrix lutea*

**French:** Léiothrix jaune **German:** Sonnenvogel **Spanish:** Leiothrix Piquirrojo  
**Other common names:** Pekin/Peking Robin; Doubtful Leiothrix ("*L. astleyi*")

**Taxonomy.** *Sylvia (lutea)* Scopoli, 1786, mountains of Anhui, China.

Probably fairly close to *Siva* and *Mesia*. Form described as "*L. astleyi*", known only from a pair of live individuals shipped from S China, is considered to represent a mutation of present species caused by long period in captivity. Birds from S Assam hills (India) named as race *luteola*, but *luteola* from *calipyga*. Five subspecies recognised.

#### **Subspecies and Distribution.**

*L. l. kumaensis* Whistler, 1943 – NW Himalayas from NE Pakistan E to N India (Uttaranchal Pradesh) India.

*L. l. calipyga* (Hodgson, 1837) – Nepal E to Bhutan, NE Indian hill states, S China (SE Xizang), and extreme NW Myanmar (S to N Chin Hills).

*L. l. yunnanensis* Rothschild, 1921 – NE Myanmar and S China (W & NW Yunnan).

*L. l. lutea* (Scopoli, 1786) – SC & E China (S Gansu and S Shaanxi E to W Hubei, S Anhui, N Zhejiang and N Fujian, S to C & S Sichuan, Guizhou and N Guangxi).

*L. l. kwangtungensis* Stresemann, 1923 – S & SE China (SE Yunnan E to C Guangxi, S Hunan and Guangdong) and extreme N Vietnam (N Tonkin).

**Descriptive notes.** 14–15 cm; 18–28 g. Small olive-grey babbler with forked tail, red bill, yellow throat, orange-yellow breast, and red to yellow wing markings. Male nominate race has yellowish-buff crown, shading to buff on nape to mouse-grey upperparts, with very long, whitish-tipped uppertail-coverts; upperwing with yellow and orange-yellow fringing and large chestnut-red basal patch on primaries. Small yellow patch at base of outer secondaries, tail glossy black, yellowish-buff lores and orbital area, pale buffish-grey ear-coverts; olive to blackish-olive submoustachial

stripe turning grey under ear-coverts and on neck sides, strong yellow on chin and throat shading to orange-rufous on upper breast, pale yellow mid-breast to vent, pale olive-grey flanks; iris dark brown to crimson; bill coral-red, black base; legs greenish-yellow to pale brown. Female is slightly smaller than male, with more greenish-olive crown, greyer ear-coverts, duller and smaller reddish wing patch. Juvenile is similar to female, but has paler bill, crown concolorous with mantle, with underparts olive-grey and whitish in centre. Race *kwangtungensis* is like nominate, but with yellow-tinged crown to nape, more olive-toned posterior upperparts, yellowish face, neck side and underparts, orange patch at base of secondaries; *kumaensis* has greener crown with more restricted yellowish wash than nominate, little or no chestnut-red wing patch but orange-red distal outer fringes of inner primaries, patch at base of secondaries orange; *calipyga* is similar to previous but yellowish above, orange-red fringes of inner primaries extending entire length of feathers; *yunnanensis* is similar to *kumaensis* above, but lores and orbital area whitish, chin to breast paler, wing with no red or orange colouring. **Voice.** Song long and complex, a rather rapid, fluty warble of up to 15 notes, variable in structure, to European ears recalling Blackcap (*Sylvia atricapilla*); second song type shorter, with fixed sequence of syllables; third type quieter and less melodic, given by male in pursuit of female. Calls include guttural, slightly nasal short abrupt "zhirk" or "shreep" notes, sometimes run together as rattling chatter, "zhri-zhri-zhri..." in aggression towards human or avian intruders (including conspecifics); also shorter, harder "zip" calls and, in alarm, dry, grating buzzy "zhriti-zhriti-zhriti..." rattles.

**Habitat.** Thick undergrowth in more open broadleaf evergreen, pine and mixed forests, forest edge, secondary growth, scrub including shrub verbena (*Lantana camara*), also abandoned cultivation, tea plantations, bamboo clumps. Feral population in Japan favours *Tsuga* and *Abies* forests and deciduous broadleaf forest with dense undergrowth dominated by bamboo; feral population in Hawaii uses both native and exotic wet forests wherever good shrub layer present (thus absent from exotic *Casuarina* and *Eucalyptus* plantations), and abundance correlated with elevation, tree biomass and abundance of fruit-bearing native and introduced shrubs. Found throughout range at 75–3400 m, mostly 900–2400 m, all year. In Bhutan summer range said to span 1800–3200 m (sometimes 3400 m), in cool broadleaf and conifer forest, including blue pine and fir forest, whereas winter records at 1000–2800 m, occasionally down to 600 m, in warm broadleaf forest.

**Food and Feeding.** Insects; also berries and seeds, including those of grass and *Rhus*. In Hong Kong study, Aug–May, 58% of 55 faecal samples contained insects and 96% fruit (at least 22 plant taxa exploited). Introduced birds in Japan found to consume seeds of at least ten species of plant, with predominance of *Ilex macropoda* and *Celastrus orbiculatus*; mean foraging height 4 m off ground, keeping especially to areas with dwarf bamboo. In Hawaii, fruits of native *Rubus* and *Vaccinium* and introduced *Fraxinus*, *Rubus*, *Psidium* and *Carica* popular, and invertebrates in 13 stomachs were lepidopterans (caterpillars, butterflies, moths), Hymenoptera (bees, wasps), flies (Diptera) and snails; spiders (Araneae) and millipedes (Diplopoda) also recorded in faecal samples. In captivity distinct preference for spiders and smooth caterpillars, shunning hard beetles (Coleoptera), legless larvae and very small insects such as aphids (Aphidoidea), and eats ants (Formicidae) only after performing anting movements. In pairs in breeding season, otherwise in small parties of 4–6 individuals, sometimes in association with bird waves; in Bhutan reported in "invariably" monospecific flocks of up to 20 individuals, moving rapidly through undergrowth. Non-breeding flocks in Hawaii have held as many as 100 birds. Forages with rapid movements in low vegetation, mainly below 3 m, and on ground; occasionally ascends trees, gleaning and plucking items, sometimes hanging upside-down, and frequently making short aerial leaps to snatch flying insects. In one study in Hawaii, foliage-gleaning and probing made up 45% of foraging activities, fruit-feeding 41%, bark-gleaning and pecking 11%, flycatching 2%, and flower-probing 1%.

**Breeding.** Apr–Oct generally, and song mid-May to Aug in Bhutan; in Japan (introduced) season extends from late Apr to early Oct; mid-brooded. Nest, built mostly by female (male supplying material), a regular or oval cup, of varying depth and solidity, made of fine and coarse grasses, dead bamboo and other leaves, leaf skeletons, moss, lichen and fine pieces of rattan, lined with fine rootlets, fine grasses, palm and other soft fibres, tendrils and fern stems, placed 0.6–1.5 m (sometimes up to 4.5 m) above ground in bush or bamboo; territoriality unclear, in Hawaii (introduced) mean home ranges measured as 3.07 ha for males and 2.68 ha for females, but extensive overlap between pairs. Clutch 3–5 eggs, normally 3–4 (in introduced Japanese population mean for 147 nests 3.4), pale blue to greenish or greenish-white, rarely white, usually with red-brown or umber-brown blotches, red-brown and purple speckles, and pale lilac streaks and clouds; incubation by both parents, mainly female, period 11.5–14 days; nestlings provisioned by both parents; nestling period in captivity 9–12 days. Fledging success in Japan (introduced population) in three successive years 2000–2002 respectively 22.6%, 14.9% and 45.3%, with nest predation greatest cause of failure. In feral population in Hawaii, 1977–1979, annual survival for 227 adults was 0.786 and for 111 hatch-year birds 0.581 (but no avian predators present).

**Movements.** Resident. Reported seasonal altitudinal displacements in Bhutan and elsewhere in Himalayas (including at Dehra Dun), with movements fairly rapid, occurring in first half Nov and second half Apr. Winter visitor in Islamabad area of Pakistan, including Margalla Hills. In Hawaii, dispersive from breeding areas, flocks sometimes moving to higher elevations.

**Status and Conservation.** Not globally threatened. CITES II. Very scarce, perhaps only vagrant, in Pakistan. Fairly common in Nepal. Common throughout temperate zone in Bhutan, where present in Thrumshingla National Park. In India, uncommon in W Himalayas to locally common in E, hence very rare on New Forest campus at Dehra Dun and rare in Dehra Dun valley (Uttaranchal); present in Eaglenest Wildlife Sanctuary and Namdapha National Park (Arunachal Pradesh). Fairly common in S China, where recorded in 17 (31%) of 54 surveyed sites (of which 52 are nature reserves), but rare in one of them, Diding Nature Reserve, in Guangxi; abundant in mountains of NW Fujian. Uncommon in Hong Kong, where population of captive origin. In Myanmar, scarce in W but common in N; common in N Vietnam. Has been heavily traded: since 1997, when it was listed on CITES Appendix II, total of 227,517 wild-caught individuals has been recorded in international trade. Feral populations have become at least temporarily established, for example: in Hawaii (recently collapsed, but has history of dramatic unexplained population fluctuations on several islands, in mid 1980s c. 98,000 in 3529-km<sup>2</sup> study area on Hawaii, 19,000 in 404-km<sup>2</sup> study area on Maui, and 1800 in 131-km<sup>2</sup> study area on Molokai), in Japan (exploding in range and numbers in past two decades, reaching density of 350–400 pairs/km<sup>2</sup> on Mt Tsukuba, in C Japan); and in Europe (France, Italy and Germany), as well as on Reunion I, in Indian Ocean.

**Bibliography.** von der Ah (1984), Ali & Ripley (1972), Ali *et al.* (1996), Amato & Eggen (2002a, 2002b), Anon, (2004c), Bangs & Peters (1928), Barker *et al.* (1999), Birand & Pawar (2004), Caldwell & Caldwell (1931), Carey *et al.*

**Habitat.** Broadleaf evergreen forest, forest edge, secondary growth, oak and pine forest, open scrub with large trees or clearings in forest. In C Laos common in dry evergreen and *Fokienia*-dominated forest. Found at 100–3000 m, reaching highest elevations in Sumatra; apparently mainly above 500 m, and to maximum of 1525 m in Indian Subcontinent, 1800 m in Thailand and Laos; in Bhutan reportedly at 400–1600 m when breeding, and thought mostly to withdraw below 1000 m in winter, but further evidence required.

**Food and Feeding.** Insects, flower buds, fruits, berries and seeds. Regularly takes nectar of the silk-cotton trees *Bombax ceiba* and *Saindhalia* (*Bemisia*) *malabarica*, coral trees (*Erythrina*), cherries (*Prunus*) and other flowers, as well as fig (*Ficus*) fruits, in one area seen to feed on scraps thrown to chickens. Occurs in pairs or in small parties of 4–15 individuals even in breeding season (at least until mid-May). Sometimes in larger parties of up to 30–40, often in association with other species in bird waves. Forages mostly in canopy of larger trees, often where foliage quite thin, and also down to lower branches of trees and taller understory vegetation.

**Breeding.** Feb–Aug. Solitary, but pairs may nest in adjacent trees. Nest, built by both sexes, described as a very deep cup or bag, made mostly of moss with some dead leaves, lined with rootlets and rhizomorphs, placed 6–9 m above ground high up on horizontal branch or suspended from thin twigs of tree (including conifer). Clutch size undocumented, eggs pale grey-green marked with small reddish-brown blotches. No other information.

**Movements.** Resident. Description as common winter visitor in Nameri National Park, in Assam (India), requires substantiation.

**Status and Conservation.** Not globally threatened. Recently (Apr 2006) observed in Royal Chitwan National Park, in Nepal, first confirmed record in country since 19th century. Common throughout foothills and C & E valleys in Bhutan, but presence limited to large areas of continuous forest, notably in Deothang area (Samdrup Jongkha district) and W slope of Mangde Chhu valley, near Zhenbang (in Royal Manas and Jigme Singye Wangchuck National Parks). Locally fairly common in India, where present in Buxa Tiger Reserve (West Bengal) and in Eaglenest Wildlife Sanctuary and Nandapha and Moulting National Parks (all Arunachal Pradesh). Common in China, where present in Dawangling Nature Reserve (Guangxi), with eight individuals seen in one day. Generally locally common in SE Asian range. Common in Nakai-Nam Theun National Biodiversity Conservation Area, in Laos. Present in Na Hang Nature Reserve and in Vu Quang Nature Reserve, in Vietnam. Common at Bukit Fraser, in Peninsular Malaysia. Present in Gunung Leuser National Park, in Sumatra.

## Genus MALACIAS Cabanis, 1851

### 277. Rufous Sibia

#### *Malacias capistratus*

**French:** Sibia casquée **German:** Schwarzappentimalie **Spanish:** Sibia Rufa  
**Other common names:** Black-capped Black-headed Sibia

**Taxonomy.** *Cinlosoma capistratum* Vigors, 1831, Simla, Himachal Pradesh, India. Genus usually merged with *Heterophasia*. May form a superspecies with *M. gracilis*. Three subspecies recognized.

**Subspecies and Distribution.** *M. c. capistratus* (Vigors, 1831) – NE Pakistan (Murree Hills) E in W Himalayas to extreme W Nepal.

*M. c. nigricipes* (Hodgson, 1839) – Nepal (except extreme W & E) and adjacent SW China (S Xizang).

*M. c. hayleyi* (Kinnear, 1939) – E Nepal E to Bhutan and NE India (W Arunachal Pradesh) and S China (Chumbi Valley, in S Xizang).

**Descriptive notes.** 21–24 cm; 28–47 g. Slender buffy-rufous babbler with black head, blue-grey in wings and tail, slender decurved bill. Nominate race has crown and head side (lores, ear-coverts, submoustachial area) black with slightly elongate feathers, forehead with greyish tinge, clear-cutting to continuous buffy-rufous nuchal collar, neck side and underparts, and shading to soft pale brown-tinged grey on lower mantle, back and scapulars, and to slightly richer rufous on rump and uppertail-coverts; tail broadly tipped grey, central feathers pale dull rufous with broad blackish subterminal tips, outer feathers mainly blackish.

greater upperwing-coverts blue-grey with white transverse band, primary coverts black, flight-feathers with bluish-white and blue-grey fringes, tertials dull rufous with blue-grey tips; iris reddish-brown; bill black; legs brownish-flesh. Sexes similar. Juvenile has crown and head sides brownish-black, upperparts brim rufous, paler rufous below, red-tipped and buff-tinged white on greater coverts. Race *nigricipes* has all-black crown, brighter brownish-rufous underparts, more brownish-grey upperparts, more rufous-chestnut rump and warmer uppertail; *hayleyi* is like previous but has colder, darker upperparts, browner tertials, brown iris. Voice. Song, heard all year but mostly Apr–Aug, a clear high-pitched, silvery, slightly descending, quickly whistled “ss-u-u-u-u” or “ss-dwi-dwi-dwi” (first note less clear) repeated every 6–10 seconds; described also as “swee-swee-swee-sweet” (first part sometimes more hurried), and similar but only slightly descending “sissuu-sissuu-sissuu”. Calls include familiar grating, rattling “twit-ti”, “trrit-tit-tit” and “kjit-jit-jit-jit”, single “twit” and “titi” notes, jarring “jhit-jhit-jhit-jhit...”, and thin “trr-trr” and “trrit-tri”; alarm a harsh “chrai-chrai-chrai”.

**Habitat.** Broadleaf evergreen forest, particularly oak; also mixed broadleaf–coniferous forest (oak, fir and chestnut, etc.), secondary growth, scrub, locally deciduous forest, borders of cultivation, gardens. Found at 1200–3410 m (below 2700 m in W, mainly 2000–3000 m in E), locally down to c. 800 m, some as low as 100 m during harsh winter conditions. In Bhutan summer range 1600–

3000 m, occasionally to 3200 m, largely coinciding with extent of oak; in winter keeps within this range but relatively small numbers descend to 800 m or even 200 m.

**Food and Feeding.** Insects and berries. Visits rhododendron and silk-cotton tree (*Bombax ceiba*) flowers in search of insects and nectar, pair in captivity caught many wild wasps (Hymenoptera) drawn into cage by aphids (Aphidoidea) under bamboo and by jam, feeding wasps to young after despoiling them; other captives noted for frequent flycatching, however small the prey. Found in small monospecific parties up to 20 individuals outside breeding season, occasionally joins mixed feeding flocks, which may contain other babblers. Arboreal, hunting in canopy and among moss-laden and lichen-covered trunks and thick understory foliage, occasionally descending to undergrowth.

**Breeding.** Apr–Aug. Nest, built by both sexes, a neat cup of green moss, dry grasses and dry leaves, firmly interwoven and lined with rootlets, pine needles or other fine material, placed 2–18 m (usually 7–8 m) above ground in tree or bush, often near extremity of branch. Clutch 2–3 eggs (usually 3 in India), pale bluish-grey, clouded, spotted and lined with various shades of brown; incubation reportedly by female alone, but both sexes incubate in captivity, where period 14 days; nestling period in captivity 15–16 days.

**Movements.** Resident; minor altitudinal displacements by small proportion of population in winter. **Status and Conservation.** Not globally threatened. Commonest and most widespread sibia in main Himalayan range. Locally frequent in Pakistan. Common in Nepal. Abundant throughout temperate zone in Bhutan, where probably the commonest forest bird species, at least in areas with good forest cover; near Zhenbang, density of 13 territories/km of road at 1600–1900 m, highest value for any avian species in area; present in Thrumshingla National Park. Common in India, but uncommon in Majhatal Harsang Wildlife Sanctuary (Himachal Pradesh); fairly common in Dehra Dun valley (Uttaranchal) and present in Buxa Tiger Reserve (West Bengal). Status in Xizang (China) unknown.

**Bibliography.** Ali & Ripley (1972), Ali *et al.* (1996), Allen *et al.* (1997), Baars (1981), Cheng Tsohsin (1987), Dodsworth (1911), Franklin (1973, 1975), Gaston *et al.* (1994), Grimmett *et al.* (1998), Inskipp & Inskipp (1991, 1993b), Inskipp *et al.* (2000), Jarsch (1981), Löffing (1984), Ludlow & Kinnear (1937, 1944), Martens & Eck (1995), Meyer de Schauensee (1984), Mishra (1997), Philipps (1903b), Rasmussen & Anderton (2005), Sankaran (1994), Sheriff (1925), Singh, A.P. (2000), Singh, P. (1995), Spierenburg (2005), Stevens (1923), Zheng Zuoxin, Jiang Zhuhua *et al.* (1980), Zheng Zuoxin, Li Dehao *et al.* (1983).

### 278. Grey Sibia

#### *Malacias gracilis*

**French:** Sibia grise **German:** Grautimalie **Spanish:** Sibia Gris

**Taxonomy.** *Hyppispetes gracilis* Horsfield, 1840, Naga Hills, India.

Genus usually merged with *Heterophasia*. May form a superspecies with *M. capistratus*. Birds from Mt Victoria, in W Myanmar, described as race *dorsalis*, but appear inseparable from those elsewhere in species' range. Treated as monotypic.

**Distribution.** NE Indian hill states (S of R Brahmaputra), N & W Myanmar and S China (W Yunnan).

**Descriptive notes.** 22.5–24.5 cm; 34–42 g. Slender, long-tailed brown and grey babbler with white underparts and grey patches in wings and tail. Crown and head side (lores, cheek and ear-coverts) are brownish-black, shading on neck side and upperparts to brown-tinged dark grey, and to pale grey on uppertail-coverts; tail with grey central feathers and broad blackish subterminal band, outer feathers increasingly blackish but with broad grey tips; upperwing black, greater coverts white basally, distal outer edges of outer primaries pale grey, basal fringes of inner primaries glossy blue-black, tertials pale grey with blackish edges; chin and

submoustachial area to underparts white, with pale grey flanks, slight buffy wash across breast and on lower underparts; iris red to brown; bill black; legs dark brown to black. Sexes similar. Juvenile has forecrown and crown duller and browner-tinged than adult, nape to uppertail-coverts and scapulars paler and browner, body paler overall. Voice. Song a repeated, very loud, strident and far-carrying series of well-spaced high-pitched shrill whistled notes (usually descending towards end, or from beginning), e.g. “tu-tu-ti-ti-ti-tu”, “ti-ti-ti-ti-ti-tu”, “ti-ti-ti-ti-tu” and “ti-tu-ti-ti-ti-tu”. Calls with harsh grating, slightly metallic “trrit-trrit”; contact calls include quiet hurried, nasal, rather squeaky “witwit-witarit” and “wit-witarit-warao”, and soft sibilant “ti-tew”.

**Habitat.** Broadleaf evergreen and deciduous forest, including oak and rhododendron forest, sometimes pine and mixed forests, degraded and secondary forest with scattered tall trees; locally deciduous forest. At 900–2800 m.

**Food and Feeding.** Insects, including bees (Hymenoptera); also berries and small fruits, including those of witch-hazel (*Bucklandia*), and seeds. Often visits tree blossoms, including those of silk-cotton trees (*Bombax ceiba*), in search of insects and nectar. Occurs in small parties outside breeding season. Forages in canopy and among moss-covered trunks and epiphytes, occasionally descending to bushes and undergrowth.

**Breeding.** Apr–Aug. Nest, built by both sexes, a deep, firm, neatly woven cup, made of grasses, moss, roots, leaves, fibres and green pine needles, plastered with green moss and cobweb, lined with grasses, grass seed stems, rootlets and rhizomorphs, placed up to 6 m above ground in crown of tree, outer branches of rhododendron or pine tree or top fork of sapling. Clutch 2–4 eggs, usually 2–3, pale bluish-grey to greenish-grey, sometimes pinkish, lightly freckled and blotched pale reddish-brown to dark brown or ash-brown; incubation of eggs and provision of chicks by both sexes; no information on duration of incubation and nesting periods.

**Movements.** Resident. Reports of some seasonal elevational movements require substantiation. **Status and Conservation.** Not globally threatened. Restricted-range species; present in Eastern Himalayas IBA. In India, common in Assam, and recently observed in Nagaland although apparently scarce there; seen in groups of 2–3 individuals in Murlen and Phawngpui (Blue Mountain) National Parks (common in former and frequent in latter), with single record from Lengting Wildlife Sanctuary, in Mizoram. Abundant in Namataung (Mt Victoria) National Park, in Myanmar, and one of the commonest bird species at higher elevations throughout the Chin Hills. Very local in China.

**Bibliography.** Ali & Ripley (1972), Bens (1956), Cheng Tsohsin (1987), Choudhuri (2005, 2006), Godwin-Austen (1870, 1874), Grimmett *et al.* (1998), Hopwood & MacKenzie (1917), Koelz (1954), Meyer de Schauensee (1984), Rasmussen & Anderton (2005), Ripley (1952), Robinson (2000), Robinson *et al.* (1998), Singh (1995), Smythies (1986), Stanford & Mayr (1941), Stanford & Treinost (1935, 1940), Stanford *et al.* (1998), Stresemann & Heinrich (1940a), Thet Zaw Nong (2003), Wickham (1929), Wood & Finn (1902).

## 279. Black-headed Sibia

### *Malacias desgodinsi*

**French:** Sibia de Desgodins **German:** Schwarzkopftimalie **Spanish:** Sibia Cabecinegra  
**Other common names:** Black-eared Sibia; White-spectacled Sibia (*robinsoni*)

**Taxonomy.** *Sibia Desgodinsi* Oustalet, 1877, Yer-ka-lo, on the Mekong [Lancang Jiang] at c. 29°03'30" N, Xizang, China.

Genus usually merged with *Heterophasia*. Until recently treated as conspecific with *M. melanoleucus*. Birds from NW Yunnan (particularly Lijiang), in S China, described as a further race, *tecta*, supposedly with more brown on upperparts, but this feature is not constant. Five subspecies recognized.

#### Subspecies and Distribution.

*M. d. desgodinsi* (Oustalet, 1877) – N Myanmar and SC & SE China (Yunnan, C & S Sichuan, W & N Guizhou, NW Hunan, W Guangxi).

*M. d. tonkinensis* (Yen Kwokying, 1934) – extreme N Vietnam (N Tonkin).

*M. d. engelbachi* (Delacour, 1930) – Bolovens Plateau, in S Laos.

*M. d. kingi* (J. C. Eames, 2002) – SE Laos and C Vietnam (C Annam).

*M. d. robinsoni* (Rothschild, 1921) – S Annam, in S Vietnam.

**Descriptive notes.** 21.5–24.5 cm; 35–49 g. Slender long-tailed babbler, grey or brown above with black head, white below, with narrow bill. Nominative race has crown, head side (lores, cheek, submoustachial area, ear-coverts) and nape black, crown with slight bluish gloss, malar line spotted black and white; upperparts pale grey with slight mauve wash, upperwing black with slight bluish gloss on fringes; tail black with bluish gloss on edges, central feathers with grey tips, outer feathers with white tips; chin, throat and underparts pure white, faint mauve-grey wash on breast and flanks, pale grey thighs; iris crimson to brown; bill

black; legs blackish to pale greyish-black. Distinguished from similar *M. melanoleucus* by having crown sharply delineated from distinctly paler mantle, tail tips greyish-white and broad (especially on central feathers), uppermost chin feathering usually white (not black), breast and flanks suffused pale grey. Sexes similar. Juvenile of nominate race apparently undescribed; juvenile *robinsoni* has crown and base colour of ear-coverts duller than adult, slightly brown-tinged upperparts, stronger breast wash. Races differ in size (smaller in S) and in plumage colour and pattern: *tonkinensis* is like nominate, but purer and paler grey above and below; *engelbachi* has white broken eyering, white upper submoustachial area (sometimes mixed with some black), dark brown mantle, scapulars and back; *kingi* has broken white eyering as previous, but upperparts drabber brown; *robinsoni* has plumage as nominate, but with broad broken white eyering, browner ear-coverts narrowly streaked whitish, submoustachial mixed dark brown or blackish and whitish (leucistic individuals of this race also recorded). Voice. Song “hi wi-wi wi wi” or “hi hwi-wi wi-wi”, similar to that of *M. melanoleucus* but slower, more structured and less descending; 6-note song reported from S Laos. Contact calls are thin, repeated “tsrrr” notes.

**Habitat.** Broadleaf evergreen forest, oak and pine forest, and forest edge, at 800–2895; some apparently as low as 350 m during harsh winter conditions in China.

**Food and Feeding.** Insects, grubs, berries and nectar. Arboreal, usually in pairs or small flocks, mostly in treetops; occasionally descends to undergrowth, particularly in search of berries, creeping about in mossy epiphytes in skulking, jerky manner. In captivity, exhibits a liking for wasps (Hymenoptera) and catches much food on the wing.

**Breeding.** Season Apr–Aug in China and Feb–Jun in S Annam. Eggs pale blue, faintly stippled darkish brown to dull mauve with larger blotches and clouds; no other information for wild-living populations. In captivity, one nest described as flimsy, clutch size 1–3 eggs, incubation period 14–16 days and nestling period 15–17 days.

**Movements.** Resident. Only minor altitudinal movements recorded.

**Status and Conservation.** Not assessed. Common in SC & S China, where recently recorded in Cenwangaiaoshan and Diding Nature Reserves, in Guangxi. Generally common in SE Asian range. In Vietnam, uncommon in Fan Si Pan National Park, in Tonkin, and present in Thuong Da Nhim and Chu Yang Sin Nature Reserves (Da Lat Plateau), in S Annam; in last-mentioned area, density estimate of 0.32 birds/ha, yielding population estimate for reserve of 2640 individuals.

**Bibliography.** Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paolai (1962), Cheng Tsohsin *et al.* (1963), Collar (2006), Deignan (1948), Delacour & Jabouille (1931a), Deng Xuejian *et al.* (1995), Dickinson (1970), Dowell *et al.* (1997), Eames (1995, 2002), Engelbach (1932), Hewston (1999), Hill *et al.* (2001), Huang Qiang *et al.* (1995), King *et al.* (2001), King & Han Lianxian (1991), Lê Manh Hùng *et al.* (2002), Lee Kwok Shing *et al.* (2006), Meyer de Schauensee (1984), Riley (1926), Robinson & Kloss (1919a), Robson (2000), Robson *et al.* (1993a, 1993b), Rothschild (1926), Smythies (1949), Stanford (1941), Stanford & Mayr (1941), Stresemann (1923c), Tan Yaokuang & Cheng Tsohsin (1964), Tordoff, Lê Manh Hùng *et al.* (2002), Tordoff, Lê Trong Dat *et al.* (2001), Vogel *et al.* (2003), Wu Zhikang *et al.* (1986).

## 280. Dark-backed Sibia

### *Malacias melanoleucus*

**French:** Sibia à tête noire **German:** Tickeltimalie **Spanish:** Sibia Dorsinegra  
**Other common names:** Black-capped Sibia

**Taxonomy.** *Sibia melanoleuca* Blyth, 1859, Mulayit Taung [16°11' N, 98°32' E], Tenasserim, Myanmar.

Genus usually merged with *Heterophasia*. Until recently treated as conspecific with *M. desgodinsi*. Races *radcliffei* and *castanopterus* intergrade in EC Myanmar (Southern Shan States). Birds in W Thailand of undetermined race, presumed to belong with nominate race of adjacent part of Myanmar. Three subspecies recognized.

#### Subspecies and Distribution.

*M. m. radcliffei* (Stuart Baker, 1922) – EC & E Myanmar, NW Thailand and NW Laos.

*M. m. castanopterus* Salvadori, 1889 – SE Myanmar.

*M. m. melanoleucus* (Blyth, 1859) – N Tenasserim (S Myanmar) and adjacent W Thailand.

**Descriptive notes.** 21–23 cm; 23–39 g. Slender, narrow-billed long-tailed babbler, dark brown above with black head, white below. Nominative race has crown, head side (lores, cheek, submoustachial area, ear-coverts) and nape black, malar line spotted black and white, nape shading

repeated loud, high-pitched, wavering whistle, dropping in pitch at end, “hrrrr’rrr’r’i-u”, “hrrrr’rrr’r’i-i” and “hrrrr’rrr’r’i”. Calls include quite harsh “trr-trr-trr-trr...” contact notes.

**Habitat.** Broadleaf evergreen forest, at 1000–2565 m.

**Food and Feeding.** Insects, grubs, berries and nectar. Usually in pairs or small flocks. Arboreal, mostly in treetops; occasionally descends to undergrowth, particularly to find berries.

**Breeding.** Feb–Jun. Nest a cup made of moss, pine needles, grasses, leaves and wool, sometimes (when near habitation) decorated with bits of string or paper, lined with pine needles and black hair-like fibres from fungi stalks, placed 2.5–7.5 m above ground and usually on small outer branches of tree or upperside of pine branch. Clutch 1–3 eggs, pale blue or green-blue, well marked with dark or dull pale red; nestlings fed by both sexes. No other information.

**Movements.** Resident.

**Status and Conservation.** Not assessed. Generally common across range. Common in Doi Inthanon National Park, in NW Thailand.

**Bibliography.** Collar (2006), Deignan (1963), Hume & Davison (1878), Lekagul & Round (1991), Livesey (1933), Robson (2000), Smith *et al.* (1940, 1943), Smythies (1986), Tizard *et al.* (1997), Wickham (1929)

## 281. White-eared Sibia

### *Malacias auricularis*

**French:** Sibia de Taiwan **German:** Weißohrtimalie **Spanish:** Sibia de Formosa  
**Other common names:** Taiwan Sibia

**Taxonomy.** *Kittaeincla auricularis* Swinhoe, 1864, Taiwan.

Genus usually merged with *Heterophasia*. Monotypic.

**Distribution.** Taiwan.

**Descriptive notes.** 22–24 cm; mean 48 g. Elegant babbler with black head, wings and tail, protracted white eyestripe, grey and rufous body. Crown is glossy bluish-black, contrasting sharply with prominent white stripe from lores through eye (including eyering) to upper rear ear-coverts, stripe ending in long filamentous plumes; neck side, mantle and upper back dull grey, lower back, rump and uppertail-coverts rufous-chestnut; upperwing glossy bluish-black with narrow whitish wingpanel, tail brownish-black with pale grey to whitish tips; throat maroon-brown becoming paler on breast, belly pinkish-rufous or salmon-buff; iris

brown; bill black; legs brownish-flesh. Sexes similar. Juvenile apparently undescribed. Voice. Song a loud, beautiful, resonant “fei fei fei yo”, “weep-weep-weep-weeeooo” or a pleasant “wii-wiiuu” wolf-whistle. Warning calls include loud, sibilant, slightly tailing-off “sirrrrrrrrr”, repeated frequently but irregularly, often interspersed with short loud hard “sip” notes.

**Habitat.** Broadleaf evergreen forest (particularly oak), mixed broadleaf–coniferous forest, sometimes spruce, fir and cedar forest, forest edge and clearings in forest; also deciduous forest outside breeding season. Found at 1200–3000 m in summer, some descending as low as 700 m, sometimes 200 m, during harsh winter weather conditions; elevational limits in N Taiwan 750–2780 m.

**Food and Feeding.** Nectar and insects, taken from flowers; also acorns (including those of oak genus *Pasania*), berries, fruits (including climbing figs) and seeds. Singly, in pairs or in small parties. Forages in middle to upper storeys, primarily in canopy, but also descends to undergrowth. Very active, and not shy.

**Breeding.** Apr–May. Nest placed in thick foliage in tree canopy. No other information available.

**Movements.** Resident; may wander to lower elevations in winter.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Taiwan EBA. Common. In Yushan National Park, recorded densities of 0.3 birds/ha in mixed coniferous forest and 0.8/ha in spruce forest, although these not preferred habitats. Study undertaken at Endemic Species Research Unit, but details of findings currently unavailable.

**Bibliography.** Cheng Tsohsin (1987), Collar *et al.* (2003), Ding Tzungsu *et al.* (1997), Hachisuka & Udagawa (1950, 1951), Koh Chaonien & Lee Peifen (2003), Meyer de Schauensee (1984), Severinghaus & Blackshaw (1976), Smith & Yu Hontsen (1992), Stattersfield *et al.* (1998), Yen Chungwei (1990).

## 282. Beautiful Sibia

### *Malacias pulchellus*

**French:** Sibia superbe **German:** Blaukopftimalie **Spanish:** Sibia Bonita

**Taxonomy.** *Sibia pulchella* Godwin-Austen, 1874, Barail Range, Assam, India.

Genus usually merged with *Heterophasia*. Recently treated as monotypic, but races appear quite distinct. Two subspecies recognized.

#### Subspecies and Distribution.

*M. p. nigroauritus* (Kinneer, 1944) – NE India (W & C Arunachal Pradesh) and adjacent S China (SE Xizang).

*M. p. pulchellus* (Godwin-Austen, 1874) – NE India (E Arunachal Pradesh S to Nagaland), N Myanmar and S China (W & NW Yunnan).

**Descriptive notes.** 23 cm; 35–50 g. Blue-grey babbler with black face and wing-coverts, dull brown tertials, broad black subterminal tailband. Nominative race has lores, forehead, area around eye and upper submoustachial stripe black, crown grey-blue, shading to blue-grey on neck side

and upperparts; upperwing with greater and primary coverts black, primaries edged pale grey, secondaries fringed grey-blue, tertials dull brown; central tail feathers dull brown with black subterminal band and broad dull grey tip, outer feathers mainly black with broader dull grey tips; chin, throat and underparts pale grey below; iris red-brown to brown; bill black; legs horn-brown to brown. Sexes similar. Juvenile is duller than adult, body tinged brown. Race *nigroauritus* differs from nominate in having clear-cut black cheeks and ear-coverts. Voice. Song a repeated loud strident "ti-ti-ti-tu-ti" (descending slightly to

wards end), described also as fluty, sibilant, gradually descending whistle, louder and more slurred and with "kink" near end, "siii-see-see-suu-suuwée" (last note higher than previous one, but both lower than rest); reminiscent of that of *M. gracilis* but higher-pitched, shriller and generally less descending, with more hurried beginning. Calls with continuous low rattling "chrrrrrrrr" or "churrururr", also very high tittering "tr-tr-tr-tr-tr-tr-rt..." trill that may continue unvaryingly for several seconds.

**Habitat.** Broadleaf evergreen forest at 1650–3000 m, occasionally to 3200 m; locally down to 300 m in NE India and 900 m in Myanmar, presumably during harsh winter weather.

**Food and Feeding.** Insects and their larvae, including beetles (Coleoptera); seeds, including those of viburnums (*Viburnum*) and evergreen magnolias or michelias (*Michelia*), also of knotgrass (*Polygonum*); fruits, including those of certain ginsengs (*Heptapleurum*), wild raspberry (*Rubus*) and witch-hazels (*Rhodoleia*); also other vegetable matter. Regularly visits blossoms of aforementioned plants, also of rhododendrons and of cherries (*Prunus*), in search of insects and nectar. Found in pairs or in small parties of up to eight or more individuals outside breeding season, occasionally singly or in larger parties of up to 25 birds; sometimes joins bird waves in company with other babblers. Frequents tall trees, feeding mostly among moss-cloaked and lichen-covered trunks and branches; also descends to undergrowth in search of berries.

**Breeding.** Apr–Jul. Nest a cup made of moss, lined with rootlets, placed near end of horizontal branch of small tree. Eggs pale blue. No other information.

**Movements.** Resident; minor altitudinal movements in winter.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Eastern Himalayas EBA. Locally common in NE India, where present in Mouling National Park, common in Namdapha National Park, and frequent in Eaglenest Wildlife Sanctuary, all in Arunachal Pradesh, but rare in Nagaland; possibly occurs also through S Assam to E Meghalaya. Uncommon in Myanmar, and uncommon in China.

**Bibliography.** Ali & Ripley (1948, 1971), Betts (1956), Birand & Pawar (2004), Cheng Tsohsin (1987), Choudhury (2001, 2003), Godwin-Austen (1874), Grimmett *et al.* (1998), Katti *et al.* (1992), King *et al.* (2001), Kinnear (1934), Ludlow (1951), Ludlow & Kinnear (1944), Meyer de Schauensee (1984), Rasmussen & Anderton (2005), Robson (1986, 2000), Singh (1995), Smythies (1940, 1949), Stanford (1941), Stanford & Mayr (1941), Stanford & Ticehurst (1935, 1938), Stattersfield *et al.* (1998), Zheng Zuoxin *et al.* (1983).

## Genus *LEIOPTILA* Blyth, 1847

### 283. Rufous-backed Sibia

#### *Leioptila annectens*

French: Sibia à dos marron German: Rotrückentimalie Spanish: Sibia Dorsirrufa  
Other common names: Chestnut-backed/Chestnut-rumped/Blyth's Sibia

**Taxonomy.** [*Leioptila*]. *annectans* [sic] Blyth, 1847, Darjeeling, West Bengal, India.

Usually placed in genus *Heterophasia*, and has been placed in *Minla*, but differs markedly in structure, behaviour and vocalizations. Until recently, race *davisoni* was thought to be a black-backed morph of *saturata*, but geographical ranges of the two are entirely discrete and both considered worthy of recognition. Individuals of this species in SE Laos of undetermined race, presumed to belong with race *roundi* of adjacent part of Vietnam. Six subspecies recognized.

#### Subspecies and Distribution.

*L. a. annectens* Blyth, 1847 – extreme E Nepal E to Bhutan, NE Indian hill states, N & W Myanmar and S China (W Yunnan).

*L. a. saturata* Walden, 1875 – E Myanmar (W of R Salween) and NW Thailand.

*L. a. mixta* (Deignan, 1948) – E Myanmar (E of R Salween), N Thailand, N & C Laos, N Vietnam (N Tonkin, N Annam) and S China (SE Yunnan).

*L. a. davisoni* Hume, 1877 – S Myanmar (N Tenasserim) and W Thailand.

*L. a. roundi* (J. C. Eames, 2002) – Vietnam (S part of C Annam) and adjacent SE Laos.

*L. a. eximia* Riley, 1940 – S Annam, in S Vietnam.

**Descriptive notes.** 18.5–20 cm; 22–29 g. Distinctive sibia, black, white and rufous-chestnut above, white below with rufescent lower flanks. Nominate race has crown and head side (lores, cheek, ear-coverts) black, nape and upper mantle black with straggly white streaks, lower mantle and scapulars mixed chestnut-rufous and black (paler rufous on scapulars), back to uppertail-coverts chestnut-rufous; black tail broadly white-tipped; upperwing mostly black, with dull rufous tips on greater coverts and whitish edges of primaries, secondaries and tertials; chin, throat and underparts, including submoustachial area, white,

rufescent-buff on lower flanks and vent; iris brown to deep crimson; bill black, yellow base of lower mandible; legs wax-yellow. Sexes similar. Juvenile has shorter bill and narrower rectrices than adult. Race *mixta* is slightly darker rufous-chestnut above and slightly paler on vent than nominate; *saturata* has black lower mantle, chestnut back to uppertail-coverts; *davisoni* is similar to previous, but with reduced white streaking on mantle and black scapulars; *roundi* also is similar, but white below more extensive, with only tinge of buff on flanks; *eximia* is dark with reduced white streaking above, uppertail-coverts black, vent deep buff. Voice. Songs with loud, clear, pretty, descending warble, "wip'-i-iu-iu-ju" (nominate race), "wii-wii-wii-er-yu" (*eximia*), and slower, more even "it wi-wiu-ju" (*saturata*); song repeated every 5–11 seconds. Calls include harsh chattering when alarmed, and rapid, syncopated, chortling alternation of short buzzy fussing notes and harder downstrokes, e.g. "fss-uss-uss-che-che-wée-whéw-che-che-wée-whéw".

**Habitat.** Broadleaf evergreen forest, sometimes semi-deciduous forest, at 1000–2650 m, locally down to 215 m in NE India and N Myanmar; only 1000–1400 m in Bhutan (where replaced at higher elevations by *Malacias capistratus*), with winter record at 600 m (although possibly resident at this level).

**Food and Feeding.** Insects, including beetles (Coleoptera), and seeds. Found singly, in pairs, or in small parties of 3–6 individuals, often in bird waves with other babblers, e.g. *Siva cyanouroptera* and cutias. Usually forages methodically in middle to upper forest storeys, typically searching for food items among moss, lichen and bark crevices on larger limbs of trees and sometimes trunks.

**Breeding.** Apr–Jun. Nest a neat and compact cup, externally of moss, moss roots, leaves and fine grasses, inwardly of grass shreds, roots, herbaceous stems, bamboo and other leaves, lined with fine fibres, fine fern rootlets and rhizomorphs, placed 2–6 m above ground on branch of small tree (generally in fork of outer branch) or in upper branches of sapling. Clutch 2–4 eggs (usually 3 in India), very variable, often very pale blue-grey or green-grey to bright pale green-blue, with reddish-brown blotches, spots and lines over pale lavender and brown secondary blotches; incubation by both sexes; no information on duration of incubation and nestling periods.

**Movements.** Resident; some displacement to lower levels may occur in winter.

**Status and Conservation.** Not globally threatened. Rare and local in Nepal. Uncommon and local in Bhutan. Generally scarce but locally frequent in India, where present in Buxa Tiger Reserve (West Bengal), rare in Nameri National Park (Assam), and present in Eaglenest Wildlife Sanctuary and Namdapha and Mouling National Parks (Arunachal Pradesh). Uncommon to locally common in China. Generally uncommon to fairly common in SE Asian range. Present in Nakai-Nam Theun National Biodiversity Conservation Area, in Laos. In Vietnam, present in Thuong Da Nhim and Chu Yang Sin Nature Reserves (Da Lat Plateau), in S Annam, and in Pu Mat Nature Reserve.

**Bibliography.** Ali & Ripley (1972), Ali *et al.* (1996), Allen *et al.* (1997), Barua & Sharma (2005), Bingham (1903), Birand & Pawar (2004), Cheng Tsohsin (1987), Choudhury (2003), Deignan (1948, 1963), Delacour & Jabouille (1931a), Eames (1995, 2002), Eames *et al.* (2001), Grimmett *et al.* (1998), Hume & Davison (1878), Inskipp & Inskipp (1991), Katti *et al.* (1992), King *et al.* (2001), Lekagul & Round (1991), Ludlow & Kinnear (1944), Meyer de Schauensee (1984), Oates (1883), Rasmussen & Anderton (2005), Robson (2000), Robson *et al.* (1993b), Round (1999), Singh (1995), Smith *et al.* (1943), Smythies (1986), Spierenburg (2005), Stanford & Mayr (1941), Stanford & Ticehurst (1935), Stresemann & Heinrich (1940a), Stuart Baker (1893, 1907), Tizard *et al.* (1997), van der Ven (2004).

3400 m), but reaches down to 1400 m where *A. egertoni* scarce (latter keeps to bushes and undergrowth and present species more in canopy where these two syntopic).

**Food and Feeding.** Mostly beetles (Coleoptera), caterpillars and other insects, also gastropods; also berries, seeds, flowers, including those of rhododendron, flower buds, moss and nectar. Outside breeding season found in small parties of 3–10 individuals, sometimes in bird waves, which often include such other babblers as minlas, sibilas and yuhinas. Forages mostly in upper branches of middle-sized trees, searching among moss and epiphytes; occasionally descends to or near ground.

**Breeding.** Apr–Jun; territories occupied and singing heard in Bhutan in Apr–Aug. Only described nest was a rather small neat compact cup, made of fine grasses with some lichen and moss on exterior, lined with rootlets, and placed in sapling. Clutch at least 2 eggs, pale pinkish-white with bold reddish-brown blotches and inky-grey secondary blotches. No other information.

**Movements.** Resident; some apparent minor movements to lower elevations during harsh winter weather at higher levels of range.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Central Himalayas EBA and Eastern Himalayas EBA. Fairly common in Nepal. Bhutan probably holds important populations, given the largely intact forest cover within the species' elevational range, including substantial stretches within protected areas; nevertheless, species mainly scarce, commonest in W valleys and Sunkosh valley, and present in Thrumshingla National Park. In India, fairly common in West Bengal, where present in Buxa Tiger Reserve, and rare farther E, where present in and/or near Eaglenest Wildlife Sanctuary, in Arunachal Pradesh. Rare in China.

**Bibliography.** Ali & Ripley (1972), Ali *et al.* (1996), Allen *et al.* (1997), Cheng Tsohsin (1987), Choudhury (2003), Grimmett *et al.* (1998), Harrison (1985), Inskipp & Inskipp (1991, 1993b), Inskipp *et al.* (2000), Ludlow & Kinnear (1937), Martens & Eck (1995), McCarthy (2006), Meyer de Schauensee (1984), Rasmussen & Anderton (2005), Ripley (1979), Spierenburg (2005), Stattersfield *et al.* (1998), Stevens (1923), Zheng Zuoxin *et al.* (1983).

## 285. Streak-throated Barwing

### *Actinodura waldeni*

**French:** Actinodure de Walden **German:** Yünnansibia **Spanish:** Actinodura de Yunán  
**Other common names:** Austen's/Walden's Barwig; Manipur Barwing (*waldeni*)

**Taxonomy.** *Actinodura waldeni* Godwin-Austen, 1874, Mount Japvo, Naga Hills, Assam, India. Has been thought to form a superspecies with *A. nipalensis*, and sometimes considered conspecific. Apparent hybrids between latter and present species (of race *daflaensis*) found in NE India (W Arunachal Pradesh). Four subspecies recognized.

#### Subspecies and Distribution.

*A. w. daflaensis* (Godwin-Austen, 1875) – S China (SE Xizang) and adjacent NE India (C Arunachal Pradesh).

*A. w. waldeni* Godwin-Austen, 1874 – NE India (S Assam, Nagaland and N Manipur) and adjacent SW part of N Myanmar (Mt Saramati).

*A. w. poliotis* (Rippon, 1905) – W Myanmar.

*A. w. saturator* (Rothschild, 1921) – N Myanmar and S China (NW Yunnan).

tips; ear-coverts dull silvery grey with pale brown streaks, submoustachial area similar but darker brown basally; chin and throat rufous with broad buff feather edges, breast similar but edging narrower, rest of underparts plain; iris creamy grey to brownish-grey or pale olive; bill dark brown or dark horn to black; legs brown or dark horn to flesh-coloured. Sexes similar. Juvenile apparently undescribed. Race *poliotis* is like nominate, but paler body plumage with more distinct buff streaking on underparts; *saturator* is like nominate, but purer grey on head, posterior upperparts more chestnut, underparts with more even and contrasting buffish streaks from chin to belly; *daflaensis* is very different from others, with greyer-shaded crown, nape and neck sides, whitish throat, breast and belly diffusely streaked with brownish-grey, and greyish-ochre lower flanks and vent, thus superficially much more like *A. nipalensis*. Voice. Song a loud, strident, slightly wavering and rising phrase, starting with a slight rattle, and repeated every few seconds, "tchrrrr-jo-jwicee" or "dddrri-juee-iwee"; sometimes a shorter "jorr-dwidu". Calls include low, rather nasal grumbling "grrr-ut grrr-ut..." and "grr-grr-grr-grr-grr".

**Habitat.** Mossy broadleaf evergreen and mixed forest, oak and rhododendron forest, fir and hemlock forest, bamboo, at 1700–3300 m; in Indian Subcontinent probably above 2135 m only in summer, some descending as low as 1500 m, locally 500 m, in winter.

**Food and Feeding.** Insects, molluscs; fruits, including those of aromatic wintergreens (*Gaultheria*), berries, including certain ginsengs (*Heptapleurum*), seeds, including those of fairy bells (*Disporum*), brambles (*Rubus*) and ardisia (*Ardisia*), flower buds, lilaceous plants, and moss. Also visits rhododendron flowers to obtain insects or nectar. Occurs singly, in pairs or in small parties of 5–10 individuals, and often joins bird waves, which may include such other babblers as minlas, sibilas and yuhinas. Forages mostly in middle storey, on branches of middle-sized trees; also in lower branches of taller trees and in low bushes, searching among moss and lichen. Clammers around mossy tree trunks, pulling apart moss to find insects.

**Breeding.** Season extends until at least Oct in India. No further information.

**Movements.** Resident; movements to lower elevations during harsh winter weather at higher levels of range have been reported, but none clearly documented.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Eastern Himalayas EBA. Locally fairly common in India, where present in and/or near Eaglenest Wildlife Sanctuary, in Arunachal Pradesh; seen traded in Kohima, in Nagaland, during 1996–2001. Fairly common in Myanmar, but rare in Natmataung National Park. Race *daflaensis* considered very rare in China (Xizang).

**Bibliography.** Ali & Ripley (1972), Betts (1956), Cheng Tsohsin (1987), Choudhury (2001, 2003), Godwin-Austen (1874), Grimmett *et al.* (1998), Harrison (1985), Katti *et al.* (1992), King *et al.* (2001), Kinnear (1934), Ludlow & Kinnear (1944), McCarthy (2006), Meyer de Schauensee (1984), Rasmussen & Anderton (2005), Ripley (1952, 1961, 1979), Robson (1986, 2000), Robson *et al.* (1998), Rothschild (1926), Singh (1995), Smythies (1940, 1949), Stanford (1941), Stanford & Mayr (1941), Stanford & Ticehurst (1935, 1938), Stattersfield *et al.* (1998), Stresemann & Heinrich (1940a), Stuart Baker (1893), Thet Zaw Naing (2003).

## 286. Streaked Barwing

### *Actinodura souliei*

**French:** Actinodure de Soulié **German:** Tonkinsibia **Spanish:** Actinodura de Tonkin  
**Other common names:** Soulie's Barwing

**Taxonomy.** *Actinodura Souliei* Oustalet, 1897, Tzeku, north-western Yunnan, China.

Race *griseinucha* considerably different from nominate, and may well warrant separation as a full species; research needed. Two subspecies recognized.

#### Subspecies and Distribution.

*A. s. souliei* Oustalet, 1897 – SC & S Sichuan and extreme NW Yunnan, in SC China.

*A. s. griseinucha* Delacour & Jabouille, 1930 – S China (C' & SE Yunnan) and N Vietnam (W Tonkin).

**Descriptive notes.** 21–23 cm. Relatively short-tailed rufous barwing with elongate and pointed crown feathers forming floppy crest, silvery ear-coverts and crown, heavy dark brown streaking above and below. Nominate race has forecrown and mid-crown feathers dark brown with bold buff-tan edges, hind-crown with elongate brown-streaked dull grey feathers; mantle and back dark brown with stony-buff feather edges forming blade-like streaks, lower upperparts with the two colours mixed and streaking less distinct; upperwing, including coverts, densely barred, rufous base colour on flight-feathers, greyer-brown on coverts and tertials; tail densely barred rufous and black all to white tail tips, latter broad except on central pair; lores, cheek and submoustachial stripe dark greyish, ear-coverts silvery grey with slight brown wash basally; underside with blade-like brown streaks on cold buff background, streaks densest on throat and breast, less distinct on lower underparts, where buff predominates, turning dirty ochrous on lower belly and vent; iris dark brown, whitish eyering; bill greyish; legs pale brownish-flesh. Differs from similar *A. waldeni* in having darker lores, more silvery ear-coverts and rear part of crown, heavy dark brown streaking above and below, contrasting buff on posterior upperparts and underparts. Sexes similar. Juvenile undescribed. Race *griseinucha* is distinctive, with blacker lores, much bolder and stronger black and ochre crown streaking, clearer and paler grey rear crown side and nape, strong ochre replacing stony-buff streaking above, becoming rufous on rear upperparts, black barring on primary coverts so dense as to be almost continuous, black barring on wings broader and on dark chestnut background, tail feathers slightly broader and blunter and with smaller white tips, streaking below darker (almost blackish-brown) and rufous-tinged ochre. Voice. Song undocumented. Calls include soft contact notes and harsh loud chirps in alarm, similar to those of *A. waldeni*.

**Habitat.** Broadleaf evergreen and semi-deciduous forest, open fir forest with bamboo, at 1700–3300 m, locally down to 1400 m; some as low as 1000 m in winter on Omei Shan (Sichuan).

**Food and Feeding.** Mainly invertebrates. Often in small, slow-moving parties; joins bird waves.

**Breeding.** No information.

**Movements.** Resident; minor altitudinal movements recorded during cold weather and heavy snow-fall.

**Status and Conservation.** Not globally threatened. Uncommon but distinctly under-recorded. Uncommon in China, where scarce at Emei Shan Protected Scenic Area. Uncommon in N Vietnam, where scarce in Fan Si Pan National Park.

**Bibliography.** Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paolai (1960), Cheng Tsohsin *et al.* (1963), Delacour & Jabouille (1930, 1931a), Dowell *et al.* (1997), Étchécopar & Hùe (1983), Huang Qiang, Deng Heli & Mao Ke (1995), Huang Qiang, Huang Yongzhao & Deng Heli (1993), Meyer de Schauensee (1984), Robson (2000), Tordoff, Lê Minh Hùng *et al.* (2002), Tordoff, Lê Trung Dat *et al.* (2001), Wang Zhijun & Chen Huojie (1983), Wang Zhijun & Wei Tianhao (1983).

**Food and Feeding.** Mainly invertebrates. Often in small, slow-moving parties; joins bird waves.

**Breeding.** No information.

**Movements.** Resident; minor altitudinal movements recorded during cold weather and heavy snow-fall.

**Status and Conservation.** Not globally threatened. Uncommon but distinctly under-recorded. Uncommon in China, where scarce at Emei Shan Protected Scenic Area. Uncommon in N Vietnam, where scarce in Fan Si Pan National Park.

**Bibliography.** Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paolai (1960), Cheng Tsohsin *et al.* (1963), Delacour & Jabouille (1930, 1931a), Dowell *et al.* (1997), Étchécopar & Hùe (1983), Huang Qiang, Deng Heli & Mao Ke (1995), Huang Qiang, Huang Yongzhao & Deng Heli (1993), Meyer de Schauensee (1984), Robson (2000), Tordoff, Lê Minh Hùng *et al.* (2002), Tordoff, Lê Trung Dat *et al.* (2001), Wang Zhijun & Chen Huojie (1983), Wang Zhijun & Wei Tianhao (1983).

## 287. Taiwan Barwing

### *Actinodura morrisoniana*

**French:** Actinodure de Taiwan **German:** Formosasia **Spanish:** Actinodura de Formosa  
**Other common names:** Formosan Barwing

**Taxonomy.** *Actinodura morrisoniana* Ogilvie-Grant, 1906, Mount Morrison, Taiwan.

Monotypic.

**Distribution.** Taiwan.

**Descriptive notes.** 18–19 cm; mean 32 g. Typical short-tailed barwing with chestnut hood, white-streaked grey breast and buff-and-rufous belly streaking. Crown and head side (lores, ear-coverts, submoustachial area) are chestnut, with dull rufous eyering, upperparts ochrous-grey, soft whitish streaks on nape and mantle becoming buffy-tan streaks on back, weakening and mingling on rump; greater coverts plain brown, primary coverts black with greyish tips, flight-feathers densely barred with black and rufous to buffish, greyer-brown on tertials; tail rufous basally, with increasingly dense black bars on buff-grey ground, and narrow white

tips; chin and throat rufous with soft buff-tan streaks, breast pale olive-grey with long soft-edged whitish streaks, belly olive-tinged rufous with long vague buff-tan streaking, mingling plainer on thighs and vent; iris dark greyish to brownish; bill dark grey to blackish or brownish-black; legs flesh-coloured to pinkish-slate. Sexes similar. Juvenile apparently undescribed. Voice. Song a loud clear "whit chiiwii" or "whit tchiyiwi" (the "whit" a short, quick introductory note, and the main part of song quavering somewhat and increasing in volume through latter half), repeated monotonously every 4–6 seconds. Rapid, slightly quavering "chiririrrit" or "jiririrrit", and "chiririrrit" "chru" or "chiririrrit chru", along with occasional short, clear "hiew", "hiu", "huu" or "juu", becoming "jia jia jia" when alarmed. Low contact notes include short "wut" notes, "wut-chk" and similar, and slightly rising "hwee" or "hwir".

**Habitat.** Mature broadleaf deciduous forest and broadleaf evergreen forest, mixed broadleaf-coniferous forest, at 1200–3000 m, mainly 1500–2700 m, with some possibly lower in winter; elevational limits in N Taiwan 2030–2780 m.

**Food and Feeding.** Mostly arthropods such as beetle larvae (Coleoptera), other insects and their larvae; also berries and seeds; berries of honeysuckle (*Lonicera*) seen taken. Found singly, in pairs or in small parties, often in company of *Malaciac auricularis*, as well as *Yuhina brunneiceps* and *Liocichla steerii*. Forages in canopy and middle storey of forest, but also down to understorey. Creeps among epiphytic growths and along branches, rummages among dead leaves, probes moss and pulls apart lichen in search of food, craning around branches and clinging to their undersides. Beetle larvae obtained by probing bark of trunks and branches.

**Breeding.** Apr–May. Nest bulky, with much moss added, placed on branch in canopy. No other information.

**Movements.** Resident. Reports of movements to lower elevations during harsh winter weather at higher levels of range, but none clearly documented.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Taiwan EBA. Common. In Yushan National Park, recorded density of 2.39 birds/ha in mixed coniferous forest, although this not a preferred habitat.

**Bibliography.** Cheng Tsohsin (1987), Ding Tsungu et al. (1997), Koh Chaonien & Lee Peifen (2003), Meyer de Schauensee (1984), Ogilvie-Grant (1906), Seeveringhaus & Blackshaw (1976), Stattersfield et al. (1998), Yen Chungwei (1990).

## 288. Rusty-fronted Barwing

### *Actinodura egertoni*

**French:** Actinodure d'Egerton **German:** Rotstimsibia **Spanish:** Actinodura de Egerton  
**Other common names:** Spectacled(!)/Himalayan/Nepal Barwing

**Taxonomy.** *Actinodura Egertoni* Gould, 1836, Nepal.

Appears to be closely related to *A. ramsayi*. Four subspecies recognized.

**Subspecies and Distribution.**

*A. e. egertoni* Gould, 1836 – C Nepal E to Bhutan and NE India (EC Arunachal Pradesh).

*A. e. levisi* Ripley, 1948 – E Arunachal Pradesh and NW Myanmar.

*A. e. khasiana* (Godwin-Austen, 1876) – Meghalaya, S Assam (N Cachar), Nagaland and Manipur, in NE India.

*A. e. ripponi* Ogilvie-Grant & La Touche, 1907 – Mizoram (NE India), and NE & SW Myanmar and S China (W & NW Yunnan).

**Descriptive notes.** 21.5–23.5 cm; 31–42 g. Long-tailed, unstreaked barwing with brownish-grey head and crest and chestnut forehead, face and chin. Nominative race has lores, upper malar area, anterior cheek, forehead and forehead central chestnut, shading to brown-edged smoky-grey elongate feathers on central crown to hindcrown; nape and neck side smudgy mid-grey, shading to ochrous-brown on upperparts; greater coverts rufous, primary coverts blackish, rest of upperwing rufous-chestnut to buffish basally with dense black-and-whitish barring distally; tail plain dull rufous-chestnut centrally, with closely but

weakly dark-banded outer feathers, all with whitish tips; ear-coverts slightly shiny pale grey with slight pinkish tinge; chin and throat dull chestnut-rufous with vague greyish streaking, shading to rufous-tinged pale pinkish-grey on breast and stronger rufous on flanks, thighs and vent, belly whitish; iris pale grey, bluish-brown, olive-yellow or brown, orbital skin grey-green; bill yellowish-brown, paler lower mandible; legs brownish-flesh to grey-brown or pale horn. Sexes similar. Juvenile has crown and nape washed warm brown. Race *levisi* is less rufescent above than nominate; *khasiana* is altogether paler, more olive-tinged above, buffier below, with more rufous-tan in wings; *riponi* is very like last, but crown greyer and with less chestnut. Voice. Song of nominate race described as a rapid, sweet, clear sequence of short piping, crystal-clear whistles, final note distinctly lower, and strophe decelerating, "(tsit-tsit-tsit) tsit-tsit-sééé-tsééé-tsééé", repeated every few seconds, also similar version with series rising slightly in pitch before dropping greatly to final low note; race *riponi* utters more warbled version with a few short notes dropping in pitch, and then repeated without pause, e.g. "ti-wi-wi-wu ti-wi-wi-wu", also as "titu-titu-tiyú titu-titu-tiyú"; *khasiana* song similar but notes said to be chipper and less modulated. Calls include excited, metallic, high-pitched rattles creating a wall of sound, and varying somewhat in pitch and tempo; also, lower-pitched, more irregular, harsh and buzzy versions, "grrit", "grrrrrit" and "gwhah" notes, and lower, harsh, buzzing, downslurred "gursh-gursh...", "gur", also "geers" notes; occasionally a quick series, "gur-geer-geer-gursh".

**Habitat.** Dense undergrowth, scrub-jungle, forest edge, shrubbery and scrub in warm broadleaf evergreen forest and secondary growth, bamboo. Breeds at 600–2600 m, mainly 1200–2400 m, perhaps lower locally in India (E Arunachal Pradesh, 300 m) and N Myanmar (215 m).

**Food and Feeding.** Insects, including grasshoppers (Orthoptera) and ants (Formicidae); also berries, including those of wild strawberries (*Fragaria*), figs (*Ficus*), and seeds, including those of "laurel". Found in pairs during breeding season; otherwise typically in small monospecific parties of 6–12 individuals. Sometimes larger bands of up to 45 birds, but moving within well-defined home range. Often associates with bird waves, particularly with other babblers such as laughingthrushes and sibilas. Forages in middle storey of forest, occasionally in canopy, among tree-orchids and epiphytes, and among dense scrub, bushes, brambles etc. along forest edge.

**Breeding.** Apr–Jul. Nest described as a largish, rather deep cup, made of fern, bamboo or other dead leaves, grasses, fibrous roots and green moss, lined with rootlets, fine moss roots and fine grasses, placed 1–7.5 m above ground in bamboo clump, bush or sapling. Clutch 2–4 eggs (usually 3 in India, and 2–3 in Myanmar), blue or pale blue-green with blackish and/or dark brown to pink

reddish-brown blotches, spots and whorls over pale lilac-grey or purplish undermarkings. No other information.

**Movements.** Resident. Movements to lower elevations during harsh winter weather reported, but none clearly documented.

**Status and Conservation.** Not globally threatened. In C Nepal rare and local, becoming slowly commoner to E of range in Himalayas. Frequent in Bhutan but less common in W; near Zhemgang, density of 1.6 territories/km of road at 1900 m; present in Thrumshingla National Park. Locally fairly common in India, where present in Buxa Tiger Reserve (West Bengal) and in and/or near Eaglenest Wildlife Sanctuary and common in Namdapha National Park (Arunachal Pradesh). One 19th-century specimen from Bangladesh, but no other records from that country. Common in Myanmar, but uncommon in Natmataung National Park. Uncommon in China.

**Bibliography.** Ali & Ripley (1972), Ali et al. (1996), Allen et al. (1997), Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paolai (1960), Choudhury (2003), Godwin-Austen (1870), Grimmett et al. (1998), Harington (1909, 1914a), Hopwood & Mackenzie (1917), Inskipp & Inskipp (1991, 1993b), Inskipp et al. (2000), Katti et al. (1992), King et al. (2001), Koelz (1954), Ludlow & Kinnear (1937, 1944), Meyer de Schauensee (1984), Rasmussen & Anderton (2005), Ripley (1952), Robson (2000), Rothschild (1926), Singh (1995), Smythies (1986), Spierenburg (2005), Stanford & Mayr (1941), Stanford & Ticehurst (1938), Stevens (1914, 1923), Stresemann & Heinrich (1940a), Stuart Baker (1893), Thet Zaw Naing (2003), Ticehurst (1933), Tymstra (1993), Venning (1912).

## 289. Spectacled Barwing

### *Actinodura ramsayi*

**French:** Actinodure de Ramsay **German:** Brillensibia **Spanish:** Actinodura de Ramsay  
**Other common names:** Ramsay's Barwing

**Taxonomy.** *Actinodura Ramsayi* Walden, 1875, Karenni State, Upper Myanmar.

Appears to be closely related to *A. egertoni*. Individuals of this species present in N Thailand and N & C Laos (like *yunnanensis* but greyer above, with buffy rufous restricted to forehead) evidently represent an undescribed race. Three subspecies recognized.

**Subspecies and Distribution.**

*A. r. radcliffei* Harington, 1910 – EC & E Myanmar.

*A. r. ramsayi* (Walden, 1875) – SE Myanmar and NW Thailand.

*A. r. yunnanensis* Bangs & Phillips, 1914 – S China (SE Yunnan, SW Guizhou, W Guangxi) and N Vietnam (Tonkin).

**Descriptive notes.** 23.5–24.5 cm; 35–43 g. Long-tailed, unstreaked barwing, densely barred on wings and tail, plain buff below, and with bold white eyering. Nominative race has forehead milky rufous-buff, shading quickly to pale rufous-tinged olive-greyish on upperparts; tail rufescent olive-grey, evenly and narrowly barred blackish-grey and with narrow white tips; primary coverts black, upperwing and coverts otherwise strongly barred with black, base colour pale greyish-brown on coverts and scapulars, rufous-tan on flight-feathers but fading distally; lores to cheek blackish, face (rear supercilium, ear-coverts and lower

submoustachial area) milky brownish-grey; chin and upper submoustachial area milky rufous-buff, shading to plain buff on underparts, but mid-belly white; iris brown; bill blackish to pale dusky horn, slightly paler tip; legs pale plumbeous to greenish-grey. Sexes similar. Juvenile apparently undescribed. Race *yunnanensis* is more rufescent above and below than nominate, has uniform buffy-rufous crown and nape and often narrow blackish throat streaks; *radcliffei* is roughly intermediate between nominate and previous in colour (both above and below), but has rufescent-brown (not blackish) lores. Voice. Song a quite quickly repeated, rather mournful, high-pitched, bouncing, descending "iee-iee-iee-iuu"; sometimes accompanied by (perhaps from female) a high-pitched, even, forced phrase of 2–3 notes, "ewh ewh ewh". Calls include low harsh "baoh" and "berh" notes.

**Habitat.** Forest edge, secondary growth, scrub and grass, taller undergrowth in broadleaf evergreen forest, bamboo; in Laos commoner in *Fokienia*-dominated forest than in dry evergreen forest. Found at 1000–2500 m; locally down to 450 m in China and to 610 m in Myanmar.

**Food and Feeding.** No information on diet; presumably invertebrates and some vegetable matter. Typically occurs in pairs or small groups, often associating with other species, including other babblers, in bird waves.

**Breeding.** Mar–Apr. One nest was a cup made of yellowish roots, lined with finer roots and with exterior interweaving of feathery material from the half-dried creeper in which it was placed, above some rocks. Clutch 2 eggs, pale blue-green with a few bold blotches and scrolls of purplish-chocolate. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common in S China, but recently recorded only in Diding Nature Reserve (Guangxi) and in none of 53 other sites surveyed. Common in much of rest of range, including in Doi Inthanon National Park, in Thailand. Frequent in Nakai-Nam Theun National Biodiversity Conservation Area, in Laos. Scarce in Tam Dao National Park, in Vietnam.

**Bibliography.** Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paolai (1960), Cook (1913), David-Beaulieu (1944), Davidson (1998), Deignan (1963), Delacour & Jabouille (1931a), Evans & Timmins (1998), Kinnear (1929), La Touche (1923), Lee Kwok Shing et al. ## 290. Black-crowned Barwing

### *Actinodura sodangorum*

**French:** Actinodure à calotte noire **Spanish:** Actinodura Coroninegra  
**German:** Schwarzscheitelibia

**Taxonomy.** *Actinodura sodangorum* J. C. Farnes et al., 1999, Ngoc Linh, Kon Tum Province, Vietnam.

Monotypic.

**Distribution.** E part of S Laos and adjacent C highlands of C Annam, in Vietnam.

**Descriptive notes.** 24 cm. Long-tailed barwing, grey-headed with dark crown, densely barred on tail, rufous below with dark throat streaks, and with bold white eyering. Has lores black, central crown to mid-nape black, with some pointed whitish feathers at bill base and dull grey-edged black forehead feathers; cheek, ear-coverts, crown side and nape slightly pinkish-tinged dull grey with vague blackish streaks; upperparts dirty dull ochre; upperwing black, buff barring on coverts, narrow buff barring on outer webs of outer primaries and dull vague chestnut barring on outer webs of inner primaries; tail pale

buffy ochre with narrow blackish bars, rufous-tinged basal fringes and narrow whitish tips; rich ochrous-rufous below, duller on rear flanks and thighs, duller and darker on vent, and with bold black streaking radiating from chin (including submoustachial area) onto throat; iris dark brown; bill horn, base of lower mandible slightly more pinkish; legs grey-horn. Differs from superficially similar *A. ramsayi* (of race *yunnanensis*) in having throat streaks bolder, crown and nape buff-tinged mid-grey with thick black cap breaking up as black streaks on nape and mantle, no rufescent tones on upperparts, tail more heavily barred, wings largely black, greater coverts with prominent buff-marked outer webs, flight feathers with tiny amount of chestnut at bases and only vestigial barring. Sexes similar. Juvenile undescribed. Voice. Song begins hurriedly, becoming more clearly

spaced and phrased at end, "tutututu'tu'tudi-duuu" or "tututututu'tu'tuee-tuuu", presumed female occasionally adding low grumbling or whining "hwerrr'r'r'r" or "hwew-hwer" notes; similar to that of *A. ramsayi*.

**Habitat.** Forest edge, secondary growth, more open broadleaf evergreen forest, tall grass and scrub adjacent to forest (broadleaf evergreen and open pine woodland), small forest fragments with banana groves amid shifting cultivation; at 1000–2400 m.

**Food and Feeding.** No information on diet; presumably invertebrates and some vegetable matter. All sightings have been of single individuals or pairs, with one record of association with *Malacius desgodinsi*. When in forest, has typically been observed in canopy and feeding around tree boles and larger moss-covered branches.

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** VULNERABLE. Restricted-range species; present in Kontum Plateau Secondary Area (which now becomes a full EBA with discovery also of *Trochalopteron ngoclinhense*). Not uncommon but very local; known from only two areas, and assumed to have a small range and population. Presumably declining in response to widespread habitat loss and degradation, including shifting cultivation and road construction, across its projected range. May, however, prefer secondary and marginal forest habitats (as does *A. ramsayi*), and perhaps less seriously affected by deforestation. Occurs in Ngoc Linh Nature Reserve, boundaries of which were established in 1999, now the subject of a conservation project.

**Bibliography.** Anon. (2006d), Butchart & Stattersfield (2004), Collar *et al.* (2001), Eames (2001), Eames, Lê Trong Trai, Nguyễn Cu & Eve (1999), Nguyễn Cu *et al.* (2000), Robson (2000), Showler, Davidson, Chanthavi Vongkhamheng & Khounmee Salivong (1998), Stattersfield & Capper (2000).

PLATE 22

Family TIMALIIDAE (BABBLERS)  
SPECIES ACCOUNTS

Genus *MYZORNIS* Blyth, 1843

291. Fire-tailed Myzornis

*Myzornis pyrrhaura*

French: Myzorne queue-de-feu German: Feuerschwänzchen Spanish: Timalí Melero

**Taxonomy.** *Myzornis pyrrhaura* Blyth, 1843, Nepal.

Relationships uncertain; further study required. Monotypic.

**Distribution.** C Nepal E to Bhutan, NE India (Arunachal Pradesh), N Myanmar and S China (S & SE Xizang, NW Yunnan).

**Descriptive notes.** 11–13 cm; 10–13 g. Bright green species with black mask and crown scalloping, red flash in black-and-white wing, red-sided tail, and rather long, thin, slightly decurved black bill. Male has crown and entire upperparts bright green, brightest around narrow black mask from bill base to behind eye, crown with rounded black feather centres (creating scalloped effect); underparts a shade paler, with dull soft-edged reddish triangle from mid-throat to upper breast, pale blue wash on lower breast and belly, deep orange-buff lower belly and vent; primary coverts tipped white, upperwing black with white tips, but

outer primaries fringed dark blue basally, white distally, inner primaries and secondaries fringed red basally and shading through yellow to white distally, tertials with white inner webs; tail dull dark green with fiery-red outer fringes and broad black tips; iris dark brown to red; bill black; legs yellowish brown. Female is similar to male but duller and less glossy, with narrow black centres of crown feathers, more pale blue on underparts, breast triangle fainter, vent duller. Juvenile apparently undescribed. **Voice.** Calls include extremely thin, high-pitched, often quickly repeated "si" notes, hence sometimes a lilting "sis-si-si-si" in irregular bursts, some notes slightly lower and stressed; used for contact.

**Habitat.** Mossy juniper and rhododendron scrub, oak-rhododendron forest, bushes, low trees in evergreen forest, and bamboo. At 2000–3950 m in summer in Indian Subcontinent and Xizang;

mainly above 2800 in Nepal and Bhutan, and descending to 1600 m in winter; at 2440–3660 m, down to 1800 m in winter, in Myanmar; rarely, to 4265 m in China.

**Food and Feeding.** Spiders (Araneae), small flies (Diptera) and other insects; also berries, including raspberries, flower nectar and tree sap. Regularly visits flowering shrubs and trees (rhododendron, *Berberis* etc.) for nectar and insects. Found singly, in parties of 3–5 individuals, or in small flocks of up to 30 (last possibly associated with concentrated food resource), often with other species, including other small babblers. Forages in bushes and shrubs, sometimes up in trees; also searches among moss on branches and tree trunks. Hovers in front of flowers and probes into them; alights on trunks to drink oozing sap; finds insects behind bark. Occasionally makes flycatching sallies.

**Breeding.** Apr–Jun in India and Nepal, but pair with juveniles in mid-Sept at 3400 m in Bhutan suggests relatively extended breeding season. Nest, built by both sexes, a globular structure of moss, lined with flakes of rhododendron bark, 1–6 m above ground and embedded in existing moss on bank or rock face or moss and lichen on trunk of large juniper. Eggs white; nestlings fed by both sexes. No other information.

**Movements.** Resident; altitudinal descent evident from Oct, return movement from Mar apparently following progressive upslope flowering of rhododendrons.

**Status and Conservation.** Not globally threatened. Generally somewhat scarce. Uncommon and local in C & E Nepal, where local in Langtang National Park. Frequently recorded but sparsely distributed throughout temperate and alpine zones in Bhutan, where present in Thrumshingla National Park. Locally common E from Sikkim to NE India, where present in and/or near Eaglenest Wildlife Sanctuary, in Arunachal Pradesh. Uncommon in Myanmar. Rare in China.

**Bibliography.** Ali & Ripley (1972), Cheng Tsohsin (1987), Choudhury (2003), Grimmett *et al.* (1998), Inskipp & Inskipp (1991), Inskipp *et al.* (2000), King *et al.* (2001), Kinnear (1934), Ludlow & Kinnear (1944), Meyer de Schauensee (1984), Rand (1967), Rasmussen & Anderon (2005), Robson (2000), Rothschild (1926), Singh (1995), Smythies (1940, 1949), Spierenburg (2005), Stanford (1941), Stanford & Mayr (1941), Stanford & Ticehurst (1935, 1938), Stevens (1923), Tymstra (1993).

Genus *MALIA* Schlegel, 1880

292. *Malia*

*Malia grata*

French: Malia des Célèbes

German: Mooswaldtimalie

Spanish: Timali Malia

**Other common names:** Celebes/Sulawesi Malia, Malia Babbler

**Taxonomy.** *Malia grata* Schlegel, 1880, Makassar District, Sulawesi. Affinities unclear; has been treated as an aberrant bulbul (Pycnonotidae). Research, including molecular-genetic analysis, is required. Three subspecies recognized.

**Subspecies and Distribution.**

*M. g. recondita* A. B. Meyer & Wilesworth, 1894 – N Sulawesi.

*M. g. stresemanni* Meise, 1931 – C & SE Sulawesi.

*M. g. grata* Schlegel, 1880 – SW Sulawesi.

**Descriptive notes.** 28 cm. Large babbler not unlike a *Turdus* thrush, dull olive-green above and bright greenish-yellow below. Nominative race has crown and upperparts dull yellowish olive-green, upperwing and tail green-tinged greyish-brown, underside lemon-yellow, brightest on chin and throat, with greenish-washed breast and flanks and dull yellow-tinged olive thighs and vent; lores and vague superciliary area yellow-stippled dull green, ear-coverts dull green with long thin yellowish streaks, submoustachial area yellow with vague dull greenish mottling; iris brown; upper mandible blackish, lower mandible yellowish;

legs greenish-brown. Sexes similar. Juvenile apparently undescribed. Race *recondita* has wings and tail more greenish-tinged, bill smaller, lower mandible duller (less distinct from upper mandible); *stresemanni* has wings and tail strongly rufous-tinged, bill size as previous. Voice. Song by group a loud mid-pitched cacophony of guttural warbling and rapid harsh chattering or grating sounds lasting for 2–2 seconds, repeated at intervals of 8–15 seconds; typically, one individual warbles while another gives continuous chatter or repeated grating note. Calling by group comprises a penetrating high whistle, “tiu”, repeated several times and immediately accompanied by rapid harsh “tsut-sut-ká-ká” (duration of about 1–2.75 seconds, intervals 1.5–5.5 seconds); other calls include thin, high repeated alarm note when flushed. Group vocalizations often introduced by single individual giving hoarse upslur followed by harsh chatter; after 12–17 seconds other birds join in with calls of various types, including slurred “chit chit chit”, nasal squeals, insistent coarse nasal calls, and brief upslurred “squeow!” whistle; such calls given while foraging, mobbing intruder, registering presence of nearby hawk (*Accipitridae*).

**Habitat.** Primary montane forest, mossy ridge-top forest, and occasionally disturbed forest, at 900–2400 m.

**Food and Feeding.** Invertebrates, including beetles (Coleoptera) and grasshoppers (Orthoptera). Uses bill to dig in rotten wood, dislodge moss and loose bark, and glean from trunks and large branches. Usually in small parties of 3–7 individuals, sometimes in pairs, and generally accompanied by Sulawesi Drongo (*Dicrurus montanus*), Rusty-bellied Fantail (*Rhipidura teysmanni*), Yellow-billed Malkoha (*Phaenocarpa caryocorythos*) and Sulawesi Leaf-warbler (*Phylloscopus sarasinorum*); sometimes forages close to Sulawesi dwarf squirrel (*Prosciurillus murinus*) and whitish dwarf squirrel (*Prosciurillus leucomus*).

**Breeding.** No information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Sulawesi EBA. Widespread and locally moderately common. Fairly common (race *recondita*) in Gunung Ambang Nature Reserve, and present in Bogani Nani Wartabone (Dumoga Bone) National Park, in N Sulawesi; fairly common in Lore Lindu National Park, in NC Sulawesi.

**Bibliography.** Coates & Bishop (1997), Ekstrom *et al.* (1998), Meise (1931b), Meyer & Wilesworth (1898b), Riley & Mole (2001), Rozendaal & Dekker (1989), Stattersfield *et al.* (1998), Stresemann & Heinrich (1940b).

## Genus RHOPHILUS

Giglioli & Salvadori, 1870

### 293. Chinese Bush-dweller

#### *Rhopophilus pekinensis*

**French:** Rhophilus de Pékin **German:** Pekingsänger **Spanish:** Timali Pekinés  
**Other common names:** Chinese/Grey-browed Babbler, White-browed Bush-dweller/Chinese Warbler, Chinese Hill Warbler, Peking Warbler

**Taxonomy.** *Drymoea* (?) *pekinensis* Swinhoe, 1868, Beijing, China.

Affinities uncertain; has been placed in family Cisticolidae. Very recent DNA analyses, however, appear to support placement in present family, where should perhaps be positioned close to genera *Chrysomma* and *Chamaea*. Proposed race *leptorhynchus* (from F Qinghai and Gansu) rather weakly defined and seems to fall within range of variation of nominate; tentatively treated as synonym of latter. Two subspecies recognized.

**Subspecies and Distribution.**

*R. p. albosuperciliaris* (Hume, 1873) – NW China from W Xinjiang E to W Nei Mongol and W Qinghai.

*R. p. pekinensis* (Swinhoe, 1868) – C & E China (SE Qinghai and C & S Gansu E to Shaanxi and NE Sichuan, and from S Nei Mongol and S Liaoning S to SW Henan and NE Hubei) and N Korea.

**Descriptive notes.** 15–17 cm. Small passerine resembling a cisticolid warbler, with graduated tail very long (half of bird's total length), plumage pale grey and sandy with heavy dark streaks above, white with pale rufous streaking below. Male nominate race has crown and upperparts buffy grey with broad dark brown streaks arranged in neat lines, streaks broader and longer on back; upperwing dark brown with pale brown fringes, tail pale brown centrally, outer rectrices dark brownish-grey with pale greyish tips; blackish lores, pale buff-grey supercilium, pinkish buff-grey ear-coverts, bold black submoustachial stripe, grey-streaked dull rufous neck side; white chin and malar area to vent,

with long rufous stripes on flanks and belly; iris yellowish-grey; bill pale brown; legs pale brownish-ochre to flesh. Female is similar to male, but tail slightly shorter, belly streaks perhaps less rich. Juvenile apparently undescribed. Race *albosuperciliaris* is larger and much paler than nominate, base colour of upperparts greyish-tinged creamy buff, supercilium buff, head side greyish-buff, underparts creamy with rufous streaks very faint. Voice. Not adequately documented. Song described as a sweet continuous “dear, dear, dear”, starting on high note that falls away quickly and then rises at start of second syllable; rich “chee-anh” calls given in duet.

**Habitat.** Dry stony montane scrub, bush-covered hill slopes, tamarisks, long grass with scattered trees (including pines) and bushes, rough lowland scrub, also reed clumps; one record from ornamental park hedge.

**Food and Feeding.** No information on diet; presumably invertebrates. Forms flocks outside breeding season, sometimes associating with other babblers. Forages in vegetation, but runs well on ground.

**Breeding.** May. Nest a substantial deep cup of soft grasses, thickly bound with strips of grass, reinforced externally with cobweb, cocoons and animal hair, placed low down in bush. Clutch 4–6 eggs, greenish-white with speckling and blotching of dark violet and earth-brown. No other information.

**Movements.** Resident, with some apparent winter displacements, e.g. to parts of S Korea.

**Status and Conservation.** Not globally threatened. Uncommon within comparatively enormous range. Around Beidaihe, in E China (S Liaoning), numbers may have increased from 1940s to 1980s, but recent large-scale land development has probably reversed this trend. Considered very common in mountains of Hebei c. 90 years ago. Records have declined in number in N Korea since 1950s. Was probably formerly a rare resident in Kyonggi-do, in S Korea, but no records since 1964.

**Bibliography.** Anon. (2003d, 2004c), Cheng Tsohsin (1987), Duckworth (2006), Etchécopar & Hile (1983), Gore & Won Pyong-Oh (1971), La Touche (1925–1930), MacKinnon & Phillips (2000), Meyer de Schauensee (1984), Oustalet (1893), Shaw Tsenhwang (1936), Tomek (2002), Vaurie (1972).

## Genus LIOPTILUS Bonaparte, 1850

### 294. Bush Blackcap

#### *Lioptilus nigricapillus*

**French:** Lioptile à calotte noire **German:** Buschschwarzköppchen **Spanish:** Lioptila Capirotada  
**Other common names:** Blackcap Mountain Babbler

**Taxonomy.** *Turdus nigri capillus* [sic] Vieillot, 1818, forests of Bruintjes Hoogte, near Somerset East, Cape Province, South Africa.

Affinities unclear. Has been suggested as being an aberrant bulbul (Pycnonotidae), but latest evidence points towards a link with “warbler” genus *Sylvia*; further research required. Monotypic.

**Distribution.** E South Africa (S along escarpments to extreme E Free State and C Eastern Cape) and W Swaziland.

**Descriptive notes.** 17–19 cm; 26–34 g. Small bulbul-like passerine with orange-pink bill, black cap and chin, olive upperparts, grey throat and breast and white belly. Has crown (including area around eye) to mantle jet-black, rest of upperparts warm olive-brown, upperwing and tail marginally darker; chin black, submoustachial area, cheek, ear-coverts, neck side and throat to belly pale grey, shading paler and more olive on flanks, thighs and vent, middle to lower belly whitish; iris reddish-brown to dark brown, very narrow pinkish eyering; bill pale orange to coral-pink; legs dull pink to brownish-flesh. Sexes similar. Juvenile is

duller and paler above, browner-washed below, bill dusky-pink. Voice. Song by male when breeding, and by female when building nest, a loud lively jumble of melodious phrases and notes, “peeu peeu peeu whit-whit-whit-whit”, “cheep-ta-woy, cheep-cheep-ta-woy”, “cho-woy, cheep-cheep-cho, cho-wee-cho”, deeper, richer and more purposeful than those of *Pycnonotus* bulbul. Alarm call a fairly loud, guttural “burgg”; soft churring at nest.

**Habitat.** Temperate and montane mist-belt broadleaf evergreen forest on slopes, in ravines and kloofs, forest edge and adjacent scrub and thickets, especially with ouhout (*Leucosidea sericea*) and sagewood (*Buddleia*). Usually at 750–1825 m, but recorded down to 600 m in winter months, and down to coast in May, then occupying coastal forests and valley bushveld, occasionally ferns and shrubs in gardens.

**Food and Feeding.** Small berries, fruits and invertebrates. Found singly, in pairs or in small groups, sometimes with other frugivores in fruiting trees. Forages quietly and unobtrusively with slow deliberate movements through middle layer of forest edge or low down in scrub, plucking fruit and gleaning insects from foliage. One often drank at small fish pond in suburban garden in winter.

**Breeding.** Oct/Nov–Jan. Nest, built by both sexes, a simple, neat cup of grass, leaves, fine blackish twigs and other twigs, roots, forbs and tendrils, lined with rootlets, bark strips, fine twigs and animal hair, placed 1–6 m above ground in fork in leafy subcanopy of tree or bush, often in tree on edge of wood or overlooking wet area. Clutch 2–3 eggs, dull white with pale brown, rusty and slate-grey streaks; no information on incubation and nestling periods. One nest parasitized by Jacobin Cuckoo (*Clamator jacobinus*).

**Movements.** Resident and partial elevational migrant. Populations breeding in high Drakensberg winter in lower forests, covering up to 300 km and intermingling with sedentary populations; occasional extralimital records S & W to coast indicate overshooting migrants or juvenile dispersal.

**Bibliography.** Anon. (1980b, 2006d), Butchart & Stattersfield (2004), Clancey (1985), Fry *et al.* (2000), Harrison *et al.* (1997), Hockey *et al.* (2005), McClelland (1999), McKechnie (1975), Stattersfield & Capper (2000), Stattersfield *et al.* (1998).

**French:** Parophasme de Galinier      **German:** Singtimalie      **Spanish:** Charlatán Abisinio  
**Other common names:** Abyssinian Babbler/Catbird

**Distribution.** Highlands of N (Simien), W & S Ethiopia.

**Descriptive notes.** 17–19 cm. Dull grey babbler-like passerine with blackish lores, whitish forehead and rufous-chestnut vent. Lores are blackish, forehead to mid-crown greyish-white, shading to dull olive-tinged mid-grey on upperparts and underparts; slaty-grey upperwing with blackish outer greater coverts and primary coverts, slaty-grey tail; mid-belly slightly purer grey, lower belly, thighs and vent rufous-chestnut; iris crimson to reddish-brown; bill black; legs dark brown. Sexes similar. Juvenile is paler grey than adult, with paler rufous vent. Voice. Male song, given throughout day (especially in rain), a fine melodious war-

bling trill lasting 3–4 seconds, becoming louder and sharper, decelerating at end, and answered by female with low dry churr or purr. Calls apparently unreported.

**Habitat.** Dense thickets and tangles of vegetation in juniper woodland, giant heather, St John's-wort (*Hypericum*), highland bamboo, olive trees, *Podocarpus* and other tall trees, often in steep-sided valleys and ravines; also in well-wooded gardens in Addis Ababa. At 2440–3655 m.

**Food and Feeding.** Juniper berries and other small fruit. Found in pairs or in parties of up to eight individuals. Generally keeps within dense tangles of vegetation; moves in purposeful bounds along branches.

**Breeding.** Jan-Jul. Nest a frail thin cup made of fine plant stems, loosely placed c. 5 m above ground on top of 2-3 small branches and vines and *Galium*, in top of *Hypericum lanceolatum* and shaded by tangle of vines. Clutch 2 eggs, pale flesh-coloured, uniformly covered with fine flesh marks and a few dark chestnut spots; incubation period 16-18 days; nestling period 15-18 days. Recorded longevity 6 years.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common resident. Present in Bale Mountains, Simien Mountains and Entoto Natural Parks, and in at least five other Important Bird Areas in Ethiopia.

**Bibliography.** Fishpool *et al.* (1996), Friedmann (1937), Fry *et al.* (2000), Hall & Moreau (1970), Mackworth-Praed & Grant (1960), Reichenow (1905), Rüppell (1845), Urban & Brown (1971), Urban *et al.* (1970), Vivero Pol (2001).

**French:** Horizorin de Dohrn      **German:** Prinzendrossling      **Spanish:** Timali de Principe  
**Other common names:** Dohrn's Thrush-babbler/Flycatcher

**Taxonomy.** *Cuphopterus dohrni* Hartlaub, 1866, Principe Island, Gulf of Guinea. Relationships uncertain. Has been considered to be a thrush (Turidae) or an Old World warbler (Sylvidae), and in recent years generally treated as an Old World flycatcher (Muscicapidae). Perhaps unlikely to belong in present family (which exhibits inability to cross large stretches of water), and vocalizations indicate possible link with warbler genus *Sylvia*; on the other hand, bill morphology similar to that of *Iladopsis*, and voice resembles also those of *Kuopeornis* and *Pyrcticus*, supporting placement in present family. Further research required. Monotypic.

[illegible]

**Habitat.** Bushes and small trees, also bases of crowns of taller trees in all wooded areas, including primary forest, secondary forest, cocoa and coconut plantations, bushy country and villages; at all elevations.

**Food and Feeding.** Caterpillars, ants (Formicidae), beetles (Coleoptera), other insects, and small snails; also berries and seeds, including those of *Trema* bushes and large African corkwood trees (*Musanga*); young fed mainly by berries. In pairs or in parties of up to eight individuals, occasionally 20; sometimes in mixed parties with Principle Golden Weaver (*Ploceus princeps*) and Principle Glossy Starling (*Lamprolaima ornatus*). Forages low among vegetation of understorey and undergrowth, gleaming in manner of a bulbul (Pycnonotidae) or a Cossypha robin-chat; pokes into bark crevices, inspects undersides of branches, climbs on trunks; sallies after insects, captured with audible snaps of bill.

**Breeding.** Jun–Sept, or possibly Jun–Jul and Sept–Jan; probably double-brooded. Nest a fragile thin-bottomed and unlined open cup made of dry leaves of herbs or dead grass; one nest, 3.5 m up in fork of small bough in cocoa tree, held two young. No other information.

**Movements, Resident.**

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Principe EBA. Abundant in cocoa plantations and forest regrowth and in other bushy country; perhaps less common in coconut plantations. Increased use of pesticides was raised as a cause for concern in early 1990s, but not subsequently.

**Bibliography.** Atkinson, Dutton *et al.* (1994), Atkinson, Peet & Alexander (1991), Borrow & Demey (2001), Christy & Clarke (1998), Dohrn (1866), Fry *et al.* (2000), Jones & Tye (1988, 2006), Keulemans (1866), de Naurois (1994), Snow (1950), Stattersfield *et al.* (1998).

## PLATE 23

## Family TIMALIIDAE (BABBLERS) SPECIES ACCOUNTS

### Genus *PTERUTHIUS* Swainson, 1832

#### 297. Black-headed Shrike-babbler

##### *Pteruthius rufiventer*

**French:** Alouette à ventre roux **Spanish:** Timali-alcaudón Ventrirrufo  
**German:** Rotbauch-Würgertimalie  
**Other common names:** Rufous-bellied Shrike-babbler

**Taxonomy.** *Pteruthius*, *rufiventer* Blyth, 1842, no locality = Darjeeling, West Bengal, India. Relationships of genus uncertain; most of recent studies suggest that it does not belong in current family, and recent molecular analyses indicate that it should be placed in the New World family Vireonidae. Two subspecies recognized.

##### **Subspecies and Distribution.**

*P. r. rufiventer* Blyth, 1842 – C & E Nepal E to NE India (Arunachal Pradesh, Nagaland, Manipur), W & NE Myanmar and S China (W & C Yunnan).  
*P. r. delacouri* Mayr, 1941 – W Tonkin (Fan Si Pan Mts), in N Vietnam.

**Descriptive notes.** 18.5–20 cm; 32–48 g. Large shrike-babbler, male with glossy black head, wings and tail and chestnut upperparts, female with black crown and yellow-green upperparts. Male nominate race has crown, nape and head side (lores, cheek and ear-coverts) black with dark blue-green gloss, upperparts chestnut; upperwing as crown, chestnut tips of tertials, tail as crown but with chestnut tips; chin and upper submoustachial area white, shading to pale grey on lower submoustachial area to mid-breast, cutting abruptly to brown-tinged pale pinkish on belly, breast side with dull yellow patch; iris blue-grey to purplish-black, orbital skin grey; upper mandible black to dusky, lower mandible pale grey or blue-grey; legs pale pinkish-brown to chocolate-brown. Female has black crown with mid-grey streaks, all-black nape, yellow-tinged olive-green upperparts, wing fringes and central tail, black primary coverts, chestnut rump and tips of tertials and tail; mid-grey head side and neck side, becoming slightly paler on breast, lower underparts darker than on male, with only vague yellowish stain on breast side. Juvenile male has crown and nape duller, tinged brown, mantle mixed with yellowish-green feathers. Race *delacouri* male is slightly darker chestnut above than nominate.

grey to purplish-black, orbital skin grey; upper mandible black to dusky, lower mandible pale grey or blue-grey; legs pale pinkish-brown to chocolate-brown. Female has black crown with mid-grey streaks, all-black nape, yellow-tinged olive-green upperparts, wing fringes and central tail, black primary coverts, chestnut rump and tips of tertials and tail; mid-grey head side and neck side, becoming slightly paler on breast, lower underparts darker than on male, with only vague yellowish stain on breast side. Juvenile male has crown and nape duller, tinged brown, mantle mixed with yellowish-green feathers. Race *delacouri* male is slightly darker chestnut above than nominate.

and paler and more pearly grey on throat. **VOICE.** Song in W Myanmar a full, rather mellow, plaintive “wip-wiyu” with slightly stressed terminal syllable, repeated at intervals of 2–5 seconds; in Nepal very similar but with longer pause after first note, “wip wu-yu” (repeated after 1–3 seconds), and another song type recorded in Nepal a more evenly spaced, slightly descending “yu-wu-uu” (repeated after 2–4 seconds); song also described as a loud, sweet, brief rich whistled “dit-du-whéuu”, first 2 notes staccato and subdued, third stressed and rapidly slurred up and down. Two types of call recorded: a curious, quick, nervous, tremulous “ukuk-wrrrri-yiwu”, first note low and throaty, second long and high-pitched (repeated after short intervals), and harsh, scolding, gruff “rrrr-rrrr-rrrr-rrrr-rrrr...” (5–7 notes) when agitated.

**Habitat.** Broadleaf evergreen forest, including mature mixed moss-covered oak and mixed oak-rhododendron, occasionally secondary growth and bamboo. In Indian Subcontinent found at 2135–2500 m, occasionally up to 3230 m in Nepal and down to 1830 m in India; 1600–2400 m in Bhutan, where occurrence dictated by presence of mature undisturbed forest; in Myanmar, recorded at 1525–2650 m (once down to 1220 m) in winter but only above 2530 m in summer; at similar elevations in China and Vietnam.

**Food and Feeding.** Insects, including weevils and other beetles (Coleoptea) and caterpillars. Occurs singly, in pairs or in small parties (commonly singly in Bhutan), sometimes in association with other species, including other babblers, in mixed feeding flocks. Lethargic and rather slow-moving. Forages usually quite high up in trees, in canopy and upper middle storey, but sometimes quite low down in undergrowth. Searches mossy branches. Habits similar to those of *P. flaviscapis*.

**Breeding.** Season Apr in Bhutan. No other information.

**Movements.** Resident; some possible seasonal elevational movements.

**Status and Conservation.** Not globally threatened. Scarce to locally frequent from C Nepal E to NE India, where present in Buxa Tiger Reserve, in West Bengal, and Eaglenest Wildlife Sanctuary, in Arunachal Pradesh; uncommon in Bhutan, where found mainly in E valleys, and present in Thrumshingla National Park. Scarce to uncommon in Myanmar, where scarce in Natmoutaung National Park. Scarce in China and Vietnam.

**Bibliography.** Ali & Ripley (1972), Allen *et al.* (1997), Bishop (1999), Cheng Tsohsin (1987), Choudhury (2000, 2003), Delacour & Jabouille (1931a), Grimmett *et al.* (1998), Inskipp & Inskipp (1991), Inskipp *et al.* (2000), King, Buck *et al.* (2001), King, Dickinson & Woodcock (1975), Meyer de Schauensee (1984), Rasmussen & Anderton (2005), Ripley (1952, 1982), Robson (2000), Robson *et al.* (1998), Rothschild (1926), Smythies (1986), Spierenburg (2005), Stanford & Mayr (1941), Stevens (1923), Stresemann & Heinrich (1940a), Thet Zaw Naing (2003).

#### 298. White-browed Shrike-babbler

##### *Pteruthius flaviscapis*

**French:** Alouette à sourcils blancs **Spanish:** Timali-alcaudón Cejiblanco  
**German:** Weißbrauen-Würgertimalie  
**Other common names:** Red-winged/Black-crowned Shrike-babbler, Greater Shrike-babbler

**Taxonomy.** *Allotrius flaviscapis* Temminck, 1836. Java.

Relationships of genus uncertain; most of recent studies suggest that it does not belong in current family, and recent molecular analyses indicate that it should be placed in the New World family Vireonidae. Proposed race *ripleyi* (from Pakistan E to W Nepal) treated as a synonym of *validirostris*, and *lingshuiensis* (Hainan) synonymized with *ricketti*. Populations in Peninsular Malaysia currently included in race *cameranoi*, but are in fact intermediate between that taxon and *schaenseei*. Individuals of this species recorded in SW, NE & SE Thailand, SW Cambodia, S Laos and C Vietnam (C Annam) have apparently not been assigned to race. Eight subspecies recognized.

**Subspecies and Distribution.**

*P. f. validirostris* Koelz, 1951 – NE Pakistan E in W Himalayas to Bhutan and all NE Indian hill states, adjacent S China (SE Xizang) and NW & W Myanmar.  
*P. f. ricketti* Ogilvie-Grant, 1904 – NE Myanmar, S & SE China (WC Sichuan S to W & NW Yunnan and E to N Fujian, also Hainan), N Thailand and N Indochina.  
*P. f. aeralatus* Blyth, 1855 – E & SE Myanmar (including N Tenasserim) and NW & W Thailand.  
*P. f. annamensis* Robinson & Kloss, 1919 – S Vietnam (S Annam) and adjacent extreme E Cambodia.  
*P. f. schauenseei* Deignan, 1946 – S Thailand.  
*P. f. cameranoi* Salvadori, 1879 – Peninsular Malaysia and Sumatra.  
*P. f. robinsoni* Chasen & Kloss, 1931 – Borneo.  
*P. f. flaviscapis* (Temminck, 1836) – Java.

**Descriptive notes.** 14 cm; 29–44 g. Medium-sized shrike-babbler with chestnut on tertials, male black-crowned and white below, with bold white rear supercilium and grey upperparts, female grey on head and with green fringes on wings and tail. Male nominate race has crown, lores, cheek and ear-coverts black, broad postocular supercilium white, upperparts mid-grey, rump greyer, upwearing and tail black with bluish gloss, tertials yellow with chestnut inner webs and tips, inner flight-feathers tipped white; throat, submoustachial area and underparts greyish-white, very vague pale greyish-buff tinge on flanks and lower belly;

iris bluish, grey, brown or chestnut; upper mandible mostly blackish, lower mandible pale bluish-slate; legs dark flesh to pale grey. Female has dull olive-grey head with vague whitish postocular supercilium, brownish olive-grey mask with whitish shaft streaks, dull olive-grey upperparts, dull olive-yellow wing fringing and tail, buffy-white underparts with olive wash on lower flanks. Juvenile male has crown grey-tinged yellowish-brown, cheeks and ear-coverts dark grey, mantle olive-brown, wing-coverts edged yellowish-white, tail tips yellow; juvenile female has head grey-brown (as mantle), ear-coverts dark slate-grey. Races vary considerably in plumage details of both sexes: *validirostris* male has tertials all dark chestnut and pinkish-brown tinge on lower flanks, female with distinct grey on crown and white postocular supercilium; *ricketti* male has ear-coverts slate-grey, shading to smoky-grey throat and breast, with flanks as previous, tertials chestnut with yellow on bases and outer webs, and with black tips (juvenile male upperparts olive-grey, crown feathers olive-grey with white shafts), female with reduced chestnut in tertials; *aeralatus* male has ear-coverts black and underparts pale grey with whiter submoustachial line, tertials and flanks as last race, female with chestnut in tertials reduced to tips; *annamensis* male is similar to previous but slightly darker grey above and paler below (thus lacks indistinct white submoustachial), no black tips on tertials (juvenile male head greyer with pale streaks, ear-coverts dusky with pale streaks, postocular supercilium less distinct, broad yellow tips on wing-coverts, breast washed buffy, undertail-coverts pale lemon-yellow), female is less buffy below, tertials much more extensively chestnut, both sexes with smaller white tips on primaries; *schaenseei* is also similar, but shorter-winged, female with little or no chestnut on tertials; *cameranoi* male is again like *aeralatus* but a tone darker above and below, females very similar; *robinsoni* is mid-way in size between nominate and continental races, male with relatively strong pinkish wash on flanks. Voice. Sings with repeated loud strident rhythmic series of notes with short weak introduction, subject to considerable (probably regional/subspecific) variation: in W Myanmar and NW Thailand “ip ch-chu ch-chu” or “itu chi-chu chi-chu”, in Peninsular Malaysia “ip chip chip ch-chip”, in S Annam (Vietnam) “ip chu ch-chu”, in Borneo “cha-chew, cha-chew” or “cha-cha-chip, cha-cha-chip” or “chu-wip-chip-chip”. Calls include short “pink”, and grating churring sounds when alarmed.

**Habitat.** Broadleaf evergreen forest, oak-rhododendron forest, coniferous forest, montane ericaceous vegetation; in Laos also in *Fokienia*-dominated forest. Found at 900–2700 m; locally down to 300 m (perhaps in winter only), in Indian Subcontinent; 2000–2135 m in Xizang and 350–3050 m elsewhere in China; 700–2500 m in mainland SE Asia; 950–2700 m in Sumatra, 1000–3000 m in Java and 750–3100 m in Borneo.

**Food and Feeding.** Insects, including grasshoppers and locustids (Orthoptera), moths and caterpillars (Lepidoptera) and beetles (Coleoptera); also berries, fruits and seeds. Found singly, in pairs or in small parties of 6–15 individuals, regularly associating with other species, including larger babblers, in mixed flocks. Forages slowly and methodically, mostly in higher canopy, working way up tree towards top, shuffling sideways along branches; inspects moss and lichen, searches mainly on main branches for insects and berries. Not shy; sometimes aggressive towards other species.

**Breeding.** Apr–Jun in India, Myanmar and China; song in Bhutan Apr–Jul; Jan–Apr in Thailand and S Annam, Apr in Laos and May–Jun in Peninsular Malaysia; breeding-condition birds in Mar in N Borneo (Sabah). Nest a loose but strong cradle or shallow cup, made of rootlets, fibres, tendrils and a few twigs, coated on outside with moss and lichen, plastered with cobweb, lined with rootlets, and suspended 4–6–13 m above ground from horizontal fork of branch of tree (including pine). Clutch 2–5 eggs (usually 3 in Myanmar, 4–5 in S China), whitish, pinkish-white or lilac-white, profusely marked with tiny flecks and spots of deep purple/purple-brown over markings of greyish and lilac; nestlings fed by both sexes. No other information.

**Movements.** Resident; seasonal altitudinal displacements in Bhutan and elsewhere in Himalayas, descending in Oct and moving upslope Apr.

**Status and Conservation.** Not globally threatened. Commonest shrike-babbler. In Pakistan, fairly common in Murree Hills but otherwise rare and local. Fairly common in Nepal. Common in temperate zone in Bhutan; near Zhemgang, density of 3–9 territories/km of road at 1600–1900 m, making it one of commonest forest birds at these elevations; present in Thrumshingla National Park. Frequent in India, where uncommon in Dehra Dun valley (Uttaranchal) and uncommon (found in oak forest) in Majhatal Harsang Wildlife Sanctuary (Himachal Pradesh); present in Buxa Tiger Reserve (West Bengal) and in Eaglenest Wildlife Sanctuary and Mouling National Park (both Arunachal Pradesh). Very common in Thailand. Locally common in China, where recently re-

corded in eight (15%) of 54 sites surveyed (of which 52 are nature reserves), including Shiwandashan National Reserve (where rare, at best) and Diding Nature Reserve (where uncommon), in Guangxi. In Laos, frequent in Dong Hua Sao National Biodiversity Conservation Area (NBCA), common above 1000 m in Nakai-Nam Theun NBCA and present in Phou Dendin NBCA. In Vietnam, present in Ba Be National Park and Na Hang Nature Reserve, in N, in four protected areas in the Annamese lowlands, and in Thuong Da Nhim and Chu Yang Sin Nature Reserves (Da Lat Plateau), in S Annam; in last-mentioned area, estimated density of 0.22 birds/ha, yielding population estimate for reserve of 4330 individuals. Common in Peninsular Malaysia. Common in Aceh, Utara and Selatan, in Sumatra, where present in Gunung Leuser National Park. Uncommon but fairly widespread in Java; uncommon in Gunung Gede-Pangrango National Park, in W of island. Locally fairly common to common in N & C Borneo, albeit uncommon in Sabah, and present in Kayan Mentarang National Park, in E Kalimantan, and in Gunung Niut Nature Reserve, in W Kalimantan. **Bibliography.** Ali & Ripley (1972), Allen *et al.* (1997), Andrew (1985), Anon. (2004c), Bangs (1921), Birand & Pawar (2004), Buij *et al.* (2006), Caldwell & Caldwell (1931), Chasen & Hoogerwerf (1941), Cheng Tsohsin (1987), Choudhury (2003), David-Beaulieu (1944), Davison (1992, 1997a), Deignan (1963), Delacour & Jabouille (1931a), Duckworth & Hedges (1998), Duckworth *et al.* (1998), Eames (1995), Eames *et al.* (2001), Evans & Timmins (1998), Grimmett *et al.* (1998), Hill (2000), Hill *et al.* (2001), Holmes (1997), Hoogerwerf (1950a), Huang Qiang *et al.* (1995), Inskipp & Inskipp (1991), Inskipp *et al.* (2000), Koelz (1954), La Touche (1923, 1925–1930), Lee Kwok Shing *et al.* (2006), Lekagul & Round (1991), Lewthwaite (1996), Li Guiyuan *et al.* (1994), Ludlow (1951), Ludlow & Kinnear (1937, 1944), MacKinnon (1988), van Marle & Voous (1988), Martens & Eck (1995), Medway & Wells (1976), Meyer de Schauensee (1946, 1984), Mishra (1997), Priemé & Heegaard (1988), Rasmussen & Anderton (2005), Reddy (2005), Ripley (1952), Robbins *et al.* (2006), Robinson (1928), Robinson & Kloss (1919a), Robson (2000), Robson, Eames, Nguyễn Cu & Truong Van La (1993a, 1993b), Robson, Eames, Wolstencroft *et al.* (1989), Rothschild (1926), Round (1999), Sheldon *et al.* (2001), Singh (2000), Smythies (1986), Smythies & Davison (1999), Sody (1956), Spierenburg (2005), Stanford & Ticehurst (1938), Stevens (1923), Stresemann & Heinrich (1940a), Thewlis *et al.* (1996), Tymstra (1993), Wu Zhikang *et al.* (1986), Yen Kwokying (1934a), Zhang Quntan *et al.* (1994), Zheng Zuoxin *et al.* (1983).

## 299. Green Shrike-babbler

### *Pteruthius xanthochlorus*

**French:** Allotrie verte **German:** Vireowürgerimalie **Spanish:** Timali-alcaudón Verde

**Taxonomy.** *Pteruthius xanthochlorus* J. E. Gray and G. R. Gray, 1847. Nepal.

Relationships of genus uncertain; most of recent studies suggest that it does not belong in current family, and recent molecular analyses indicate that it should be placed in the New World family Vireonidae. Four subspecies recognized.

**Subspecies and Distribution.**

*P. x. occidentalis* Harington, 1913 – W Himalayas from NE Pakistan E to W Nepal.  
*P. x. xanthochlorus* J. E. Gray & G. R. Gray, 1847 – C Nepal E to Bhutan, NE India (C Arunachal Pradesh) and adjacent S China (SE Xizang).  
*P. x. hybrida* Harington, 1913 – NE India (Nagaland S to Mizoram) and W Myanmar.  
*P. x. pallidus* (David, 1871) – N Myanmar, and SC & SE China from SE Gansu and S Shaanxi S to W & N Sichuan, Yunnan (except S) and S Guizhou, and S Zhejiang and N Fujian.

**Descriptive notes.** 12–13 cm; 14–15 g. Small shrike-babbler with relatively small bill, greyish head, olive upperparts, whitish-grey throat and breast and pale yellow belly. Male nominate race has forehead to nape slaty mid-grey, sometimes with sootier smudge on hindcrown, upperparts drab olive-green; upwearing blackish, outer fringes as upperparts, narrow whitish bar along tips of greater coverts, blackish primary coverts; tail as upperparts, but outer feathers blackish distally and with narrow white tips; lores, cheek and ear-coverts mid-grey, mixed with olive on ear-coverts, throat and underparts whitish, yellowish-olive wash on lower throat side, behind ear-coverts and along flanks; iris dark brown to grey; bill dark horn, blue-grey on lower mandible; legs flesh-grey or brown to smoky brown. Female resembles male but has paler grey crown. Juvenile has underparts duller, more olive-brown than adult, grey of head and face not contrasting with upperparts. Race *occidentalis* has ashy-grey crown and nape and greyer upperparts than nominate; *pallidus* is like previous, but crown colour extends onto mantle, has white eyering, flanks and vent much brighter yellowish-green, wing fringes grey (not green), juvenile male resembles female; *hybrida* is like nominate, but with white eyering. Voice. Song a monotonous, fairly high-pitched series, repeated every 2–8 seconds, variable, a fairly well-spaced “whitu-whitu-wheel”, “wheel-wheel-wheel” and “chuiwi-chuiwi”, or well-spaced “chiev-chiev...” (2–4 notes), or faster, slightly tremulous “whitwhitwhitwhit...” (4–6 notes), or fairly fast, shorter (4–5 notes) “whiwhiwhiwhi...”, also rather fast “chiwichiwichiwichi...” (4–5 notes). Songs sweeter, more slurred and piercing, less metallic and chirpy, than those of *P. melanotis* and *P. aenobarbus*. Calls include a nasal wheezy “nyeeep, nyeeep”, “jerr”, “jerr-jerr”, “jer-ri” and higher “jerri”, as well as soft “ik”, “uk” and “jep” contact notes.

**Habitat.** Temperate broadleaf and conifer forest, e.g. oak and mixed oak-rhododendron forest, mixed broadleaf-coniferous forest. Found at 210–3600 m in Indian Subcontinent and SE Xizang, sometimes descending to 1200 m in winter, rarely to 700 m in Bhutan; in SC & E China recorded at 900–3600 m, some descending to 760 m in winter; 1700–2800 m in Myanmar.

**Food and Feeding.** Ants (Formicidae), beetles (Coleoptera) and other insects; also berries and seeds. Found singly, in pairs or in small groups of up to four individuals, often in association with mixed-species flocks, including tits (Paridae), *Phylloscopus* leaf-warblers and other babblers. Strictly arboreal, as congeners; behaviour sluggish, and reminiscent of that of North American vireos (*Vireo*).

**Breeding.** Apr–Aug throughout range. Nest a flimsy, deep purse or cradle, made of fine root fibres and hair-like lichen or moss, bound together with cobweb, lined with rootlets or black wool, outwardly decorated with a few flakes of lichen, and suspended 1.5–8 m above ground with cobwebs, hammock-like, from fork of small outer branch of tree. Clutch 2–4 eggs, cream with red-brown blotches. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Rare and very local in Pakistan, including Palas Valley, in North-West Frontier Province. Uncommon to locally common in NW Indian Himalayas SE to W Nepal; significant proportion of world population judged to be in Shey-Phoksundo

including in Guiting County Guangxi (China) (Zhang et al. 1987). Other records include: Hong Kong (Mingren 1960), India (Srinivasan & Srinivasan 1972), Iran (Nasr 1972), Israel (Graham 1972), Japan (Hirakawa 1972), Korea (Lee 1972), Laos (Cheng Tsochia 1987), Davidson et al. (1997), Mongolia (Ali & Ripley 1972), Andrew (1985), Anon. (2004), Argentina (Tschida 1987), Australia (Jennings 1963), Delacour & Jabouille (1931a), Duckworth et al. (1998), Farnes (1995), Farnes et al. (2001), Evans & Timmins (1998), Grimmer et al. (1998), Koez (1954), Lee Kwai Sing et al. (2006), Legaki & Kynd (1991), MacKinnon (1988), van Marle & Vogus (1988), Meyer de Schauensee (1946, 1984), Rasmussen & Anderson (2005), Robson (2000), Robson et al. (1993a, 1993b), Round (1999), Smythes (1986), Sody (1956), Thewlis et al. (1996), Timmins & Trinh Viet Cuong (1999), Vordeman (1895), Yen Kwokying (1934a).

PLATE 24

PLATE 24

## PLATE 24

## Family TIMALIIDAE (BABBLERS) SPECIES ACCOUNTS

### Genus *ERPORNIS* Hodgson, 1844

#### 302. White-bellied Erpornis

##### *Erpornis zantholeuca*

French: Erpornis à ventre blanc German: Grünrückenerpornis Spanish: Yuhina Ventriblanca  
Other common names: White-bellied Yuhina

**Taxonomy.** *Erpornis* [zantholeuca] Blyth, 1844. Nepal.

Affinities uncertain. Formerly treated in genus *Yuhina*, and has been placed in *Stachyris*, but molecular evidence supports long-held suspicion that no relationship exists with either of those; moreover, recent studies suggest that this species belongs outside current family, and possibly with the New World vireos (Vireonidae). Geographical variation trivial, and some named races considered untenable; thus, *griseilioris* (from SE Yunnan and Guizhou E to Taiwan) is synonymized with *tyrannulus*, and *sordida* (E Thailand and S Indochina) and *interposita* (Peninsular Malaysia) with nominate. Five subspecies recognized.

##### **Subspecies and Distribution.**

*E. z. zantholeuca* Blyth, 1844 – Nepal, Bhutan, all NF Indian states, E Bangladesh, S China (W & N Yunnan), and throughout SE Asia (except for N & SE Thailand and N Indochina).

*E. z. tyrannulus* (Swinhoe, 1870) – SE China (SE Yunnan and S Guizhou E to Jiangxi and Fujian, including Hainan and Hong Kong), Taiwan, N Thailand and N Indochina.

*E. z. canescens* Delacour & Jabouille, 1928 – SE Thailand and SW Cambodia.

*E. z. saani* Chasen, 1939 – NW Sumatra.

*E. z. brunescens* (Sharpe, 1876) – Borneo, including Pulau Laut (off SE coast).

**Descriptive notes.** 11–13 cm; 8–17 g. Small passerine resembling a yuhina, yellowish-green above and greyish-white with yellow vent below, with short crest, squared-off tail, and mostly pale, sharp, slender bill with tip slightly bent over, and rather short and dainty legs. Nominant race has crown (with slightly elongate feathers), upperparts and tail yellowish-green, upperwing fringed yellowish-green; lores greyish-green, this colour extending vaguely over eye, cheek and ear-coverts pale silvery grey; underside greyish-white, whitest on central area from chin to belly, vent pale yellow; iris grey, chestnut, ruby-red or dark brown; bill pinkish, culmen brown; legs greyish-rosy to whitish-flesh. Sexes similar. Juvenile is duller than adult, upperparts and secondaries with brownish cast. Race *tyrannulus* is greener above and greyer below than nominate; *canescens* has faint greyish wash on crown and upper mantle; *brunescens* is like nominate but duller, slightly brownish-tinted, particularly above; *saani* resembles last, but upperparts greener, not so yellow, crown darker. Voice. Song a short high-pitched descending trill, “si-ti-ti-ti”, or rising and falling “ss-sss-sse-se-se”, or only rising and with rapid delivery (trilled), “chechecheche”. Typical calls loud peevish nasal “nher-nher” or “jeeer-jeeer-jeeer” notes, interspersed with chirring notes and dry trills; also “hihi” notes, call of foraging individual in Taiwan a rapid rising quiet tinkle, “didi-didi”, lasting c. 0.5 seconds.

**Habitat.** Broadleaf evergreen forest, secondary growth, selectively logged forest, light deciduous forest, mixed broadleaf-pine forest, moss forest, bamboo, also upland heath and overgrown rubber in N Borneo (Sabah). Found at 180–2300 m, rarely to 2400 m, in Indian Subcontinent, once 3650 m in Bhutan; 360–1150 m in China but 1525–3300 m in Taiwan, some possibly descending a little in winter (although limits in N Taiwan given as 50–1850 m); up to 2650 m in SE Asia, 550–1100 m in Sumatra and to 1700 m in Borneo.

**Food and Feeding.** Small grasshoppers and bush-crickets (Orthoptera), and other insects and their larvae, particularly small caterpillars; also berries, soft figs and flower nectar, occasionally seeds. Less gregarious than other yuhinas. Found singly all year, but also in pairs or small parties, and often in company with mixed flocks of warblers (Sylviidae) and other small babblers (e.g. minlas). Frequents lower canopy and higher bushes, in middle storey. Often hangs upside-down in manner of a tit (Paridae).

**Breeding.** Mar–Jun in Indian Subcontinent and Jan–Aug in SE Asia; birds in breeding condition Jan–May, Oct and Dec and dependent juvenile Aug and Dec in Borneo. Nest, built by both sexes, a small, deep cradle made of fine grass stems, moss, rootlets, small dry leaves, finely shredded brown or other fibres, sometimes plentifully compacted with cobweb, lined with fine dark leaf stems, fine grasses and whitish fibres, suspended 0.5–2 m above ground (sometimes up to 5.5 m) between horizontal twigs of tree, bamboo or shrub. Clutch 2–3 eggs in India, Myanmar and Peninsular Malaysia, white, creamy white or with faint pink tinge, thinly marked with speckles and blotches of pale pinkish-red or pale red-brown. No other information.

**Movements.** Resident. In Taiwan, higher elevations usually visited only in post-breeding dispersal period. Reports of local seasonal movements (e.g. in India, regarded as regular winter visitor in Nameri National Park and local migrant to Kaziranga National Park, in Assam) improbable and require substantiation.

**Status and Conservation.** Not globally threatened. Locally fairly common to common in SW, C & E Nepal. Relatively uncommon but fairly widespread in Bhutan, where present in Thrumshingla National Park. Locally fairly common in India, but scarce or rare in hills of Assam; in NE India, present in Buxa Tiger Reserve (West Bengal), with 12 birds/km<sup>2</sup> in hill forest, and in (at least) Eaglenest Wildlife Sanctuary and Nandapha and Mouling National Parks (Arunachal Pradesh), Balphakram National Park, in Meghalaya, Nameri National Park and Barail Reserve Forest, in Assam, and Ngengpui Wildlife Sanctuary and Dampa Tiger Sanctuary, in Mizoram. Locally common in SE Bangladesh. Fairly common or locally common and widespread in S China, where recently recorded at 31 (57%) of 54 sites surveyed (of which 52 are protected areas), including Shiwandashan National Nature Reserve (where rare) and Diding Nature Reserve (where common), in Guangxi. Uncommon to common in Taiwan. Scarce and localized in Hong Kong, but spreading and increasing in numbers following colonization c. 1980. Generally common in SE Asian range. Uncommon throughout Myanmar, but very common in Thailand. In Laos, common and/or present in Xe Pian National Biodiversity Conservation Area (NBCA), and in Phou Xang He, Phou Dendin, Dong Hua Sao, Xe Bang Nouan, Nakai-Nam Thuen, Hin Namno, Nam Kading, Phou Khaokhoay and Phou Xiang Thong NBCAs. In Vietnam, present in Ba Be National Park and Na Hang Nature Reserve, in N, and in Thuong Da Nhim and Chu Yang Sin Nature Reserves (Da Lat Plateau), in S Annam, and in twelve protected areas in the Annamese Lowlands EBA. Rare in Aceh, in Sumatra, where race *suani* known from one specimen and three other records, two in Gunung Leuser National Park. Uncommon generally in Borneo, but common in N (Sabah); present in Similajau National Park, in Sarawak.

**Bibliography.** Ali & Ripley (1948, 1971), Allen *et al.* (1997), Anon. (2004c), Barua & Sharma (1999, 2005), Birand & Pawar (2004), Buij *et al.* (2006), Caldwell & Caldwell (1931), Carey *et al.* (2001), Chasen (1939), Chasen & Hoogerwerf (1941), Cheng Tsohsin (1987), Cheng Tsohsin & Cheng Paolai (1962), Choudhury (2003), David-Beaulieu (1932, 1939, 1944, 1950), Davidson (1998), Davidson *et al.* (1997), Davison (1997b), Deignan (1963), Delacour & Jabouille (1931a), Duckworth & Hedges (1998), Duckworth & Kelsh (1988), Duckworth, Tizard *et al.* (1998), Duckworth, Wilkinson *et al.* (1997), Eames (1995), Eames, Eve & Tordoff (2001), Eames, Steinheimer & Ros Bansok (2002), Engelbach (1932), Evans & Timmins (1998), Evans *et al.* (2000), Grimmett *et al.* (1998), Hachisuka & Udagawa (1950, 1951), Hill (2000), Holmes (1996, 1997), Hume (1880), Hume & Davidson (1878), Inskipp & Inskipp (1991), Inskipp *et al.* (2000), Johns (1989), Katti *et al.* (1992), King & Han Lianxian (1991), King & Liao Weiping (1989), Koh Chaonien & Lee Peifen (2003), La Touche (1923, 1925–1930), Lê Manh Hùng *et al.* (2002), Lê Xuân Canh *et al.* (1997), Lee Kwok Shing *et al.* (2006), Lekagul & Round (1991), Lewthwaite (1996), Ludlow & Kinnear (1944), van Marle & Voous (1988), Mayr (1938), Medway & Wells (1976), Meyer de Schauensee (1984), Neath (2001), Nguyễn Duc Tu *et al.* (2001), Rasmussen & Anderton (2005), Rheindt (2004), Robbins *et al.* (2006), Robinson (1928), Robinson & Kloss (1919a), Robson (2000), Robson, Eames, Nguyễn Cu & Truong Van La (1993a), Robson, Eames, Wolstencroft *et al.* (1989), Sharpe (1889), Sheldon *et al.* (2001), Showler, Davidson, Chanthavi Vongkhamheng & Khounmee Salivong (1998), Showler, Davidson, Khounmee Salivong & Khannkhoun Khounboline (1998), Singh, A.P. ## Genus *KAKAMEGA* Mann *et al.*, 1978

### 303. Grey-chested Kakamega

#### *Kakamega poliothorax*

**French:** Kakamega à poitrine grise

**Spanish:** Tordina de Kakamega

**German:** Graubrust-Drosseltimalie

**Other common names:** Grey-chested Akalat/Illadopsis/Babbler/Thrush-babbler

**Taxonomy.** *Alethe poliothorax* Reichenow, 1900, Bangwa (c. 5°15' N 10°25' E). Cameroon. Affinities uncertain. Has been placed in genus *Malacocincla*, and possibly belongs in *Modulatrix*; recent molecular research indicates possible relationship with the sugarbirds (Promeropidae), whereas some evidence suggests that it may belong in the thrush family (Turdidae). More study needed. Despite fragmented distribution, geographical variation virtually non-existent. Monotypic. **Distribution.** SE Nigeria, W Cameroon and Bioko I (Fernando Póo); E DR Congo, W Uganda, SW Rwanda, W Burundi and W Kenya.

**Descriptive notes.** 16.5 cm; 30–42 g. Thrush-like passerine, reddish-brown above, grey and white below, with rather long stout legs; very shy. Crown and forehead are dark rufous-brown with thin pale mottling, lores dark, head side (superciliary area, cheek, ear-coverts and neck side), upperparts and upperwing rich reddish-brown, slightly darker chestnut tail; chin, submoustachial area and throat off-white with grey mottling, upper breast and flanks grey, lower breast paler and shading to whitish on lower belly, with grey thighs and vent; iris reddish-brown; upper mandible black, lower mandible slate-grey; legs slate-blue. Sexes similar.

Juvenile has more blackish-grey head than adult and duller, more gingery upperparts, more olive-brown breastband, iris brown. **VOICE** Song, from low in vegetation and singly (sometimes within a group, but not in chorus), a loud, clear, melodious whistling, almost like that of Old World oriole (*Oriolus*) in quality, repeated several times before switching to another combination of notes, “pyoo-pyoo-tseewo” or “pyaw-pyaw-pyoo-pyi”, rather monotone but with loud and soft notes often alternating (“pée-patyée-patyóó”), sometimes longer, sometimes more rapid with bubbling quality, “trilutruleo”; described also as an attractive rising and falling fluty “t’iyew-t-t’chloo”. Has warbling call, “chee-cheerlee-cheerlee-chii-chee-cher-chii-ri-uu”, last note trilled, and loud “chee-wee, chee-wee, chee-wee, chee-wee...”, explosive “chichichichi” and liquid “tuituituituituit” calls, a thrush-like “chirp”, also a harsh chattering alarm, “kertakertaker” or “shrank-shrank”.

**Habitat.** Mature and secondary montane forest, especially near streams, also (DR Congo) transition forest and high-elevation gallery forest; in Rwanda, only in shady forest, especially by streamsides, in damp hollows and on slopes with Acanthaceae and tree-ferns. At 700–2200 m in Cameroon; 1830 m on Bioko; 1525–2440 m in DR Congo, and 2135–2440 m in Uganda.

**Food and Feeding.** Invertebrates. Usually found singly or in pairs, on or near ground. Turns over dead leaves and creeps about quietly and unobtrusively in thick undergrowth. Often follows swarms of army ants (*Dorylus*), then associating with other species in mixed flocks; occasionally comes into more open areas at such times.

**Breeding.** Breeding-condition birds in Apr and Nov in Cameroon and Jan–Feb and April in DR Congo; increase in singing intensity and alarm-calling in Oct in Rwanda; birds with brood patches in Aug–Sept in Uganda. Nest a deep cup made of leaves and moss, placed on ground in hollow under fallen tree. Clutch 2 eggs, “whitish”. No other information.

**Movements.** Resident; record at 580 m on Mt Cameroon may have involved an elevational migrant. **Status and Conservation.** Not globally threatened. Generally uncommon to rare, but locally common. Common in SE Nigeria; widespread and generally uncommon in W Cameroon. Uncommon to fairly rare in E DR Congo; present in Nyungwe Forest Reserve, in Rwanda, and Bururi Forest Nature Reserve, in Burundi; fairly common at Ruhija in Bwindi-Impenetrable National Park, in Uganda, and present in Ruwenzori National Park. Local and scarce in Kakamega Nature Reserve and North and South Nandi Forest Reserves, in Kenya, and now extinct on Mt Elgon and Lerundo.

**Bibliography.** Bannerman (1953), Borror & Demey (2001), Britton (1980), Carswell *et al.* (2005), Chapin (1953), Dowsett-Lemaire (1990), Elgood *et al.* (1994), Fry *et al.* (2000), Holyoak & Seddon (1990), Lewis & Pomeroi (1989), Louette (1981), Mann (1980, 1985), Mann *et al.* (1978), Stevenson & Fanshawe (2002), Stuart (1986), Williams & Arlott (1980), Willis (1983), Zimmerman *et al.* (1996).

## Genus *MODULATRIX* Ripley, 1952

### 304. Spot-throat

#### *Modulatrix stictigula*

**French:** Modulatrice à lunettes

**German:** Fleckenkehltimalie

**Spanish:** Tordina de Anteojos

**Taxonomy.** *Turdinus stictigula* Reichenow, 1906, Mbaramo, Usambara, Tanzania. Affinities uncertain. Thought not to be long in present family; has been considered to belong with the bulbuls (Pycnonotidae) or the thrushes (Turdidae), but recent molecular studies suggest that it is closest to the sugarbirds (Promeropidae). Further research needed. Proposed race *pressa* (from S of range) considered undiagnosable, as characters on which it was based (and others, more recently used) are not apparent in large series of specimens. Treated as monotypic. **Distribution.** Mountains of E & S Tanzania (S from Usambaras and Nguru Mts, in NE) and extreme N Malawi.

**Descriptive notes.** 15–17 cm. Dark brown babbler-like passerine with dull rufous breast and dark-mottled buffy throat; restless but shy. Crown and upperparts are dark rufescent olive-brown, upperwing with chestnut fringes, tail chocolate-chestnut; lores deep chestnut-brown, cheek and ear-coverts the same with tiny buff shaft streaks; chin, submoustachial area and throat buffy-tan with blackish tips, lower neck side and breast to belly shiny rufous-tan, shading buffier on mid-belly and olive-chestnut on flanks and thighs, vent dull rufous; iris dark brown, off-white evering; upper mandible blackish, lower mandible grey-brown; legs dark brown. Sexes similar. Juvenile is slightly paler below, throat less mottled than adult. **VOICE.** Song a loud, shrill, slurred whistling with some long higher notes, varying greatly regionally and individually, e.g. “skureet chirreet siureeeet sreet see sheeu-tsi-chiu, seceeeet, swee-ir-si-rééó”, final note loudest, or “eit, seeyee, heet, eeree, reeze, peeyer”; also a shorter “chiu chi-chi-chééó” and shrill, descending “siuuuu”, repeated several times. Alarm call a hard 3-note “jeir jeir jeir” or “chew churri”.

**Habitat.** Montane forest, including dense high-elevation thickets, locally also degraded forest (although in E Usambaras degraded forest apparently unsuitable); also undergrowth and shrubbery at forest edge, gardens. At 900–2700 m, mainly above 1200 m; mid-altitude wet luxuriant forest and drier forest at higher elevations in Ndundulu; 1750–2000 m, commoner above 1800 m, in Malawi.

**Food and Feeding.** Insects and berries reported. Probes in leaf litter and flicks leaves with bill; runs along forest floor or hops, with tail held slightly elevated. Solitary, in pairs or in (probably family) groups of 3–4 individuals. Sometimes attends ant columns.

**Breeding.** Birds in breeding condition in Oct–Mar (peak Nov–Dec) in Tanzania; peak in singing Feb–Mar in Malawi. Nest in one case a neat cup of twigs lined with felt of leaf skeletons, placed 1–6 m above ground in fork of forest sapling. Clutch 2 eggs, pinkish with heavy crimson blotches and scrawls. No other information.

**Movements.** Resident; Dec record at 600 m in dry bushland suggests some altitudinal movement.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Tanzania–Malawi Mountains EBA. Uncommon to abundant, and especially numerous at higher elevations. Common in Ndundulu Mts in both wet and drier forests, and in the Udzungwa National Park as many as 74 pairs/km<sup>2</sup>. In E Usambaras, the Nilo Forest Reserve holds a high density of this species and may be of particular importance. Density of 1 singing bird/ha in Malawi, where species present in Wilindi-Matipa Forest Reserve.

**Bibliography.** Britton (1980), Dinesen *et al.* (1993), Dowsett-Lemaire (1989), Dowsett-Lemaire & Dowsett (1983, 2006), Keith *et al.* (1992), Moyer (1993), Ripley & Heinrich (1969), Slater & Moreau (1932), Seddon *et al.* (1999a, 1999b), Stattersfield *et al.* (1998), Stevenson & Fanshawe (2002), Zimmerman *et al.* (1996).

Jensen & Stuart (1982), Keith *et al.* (1992), Moreau & Moreau (1937), Moyer (1993), Newmark (1991), Ryan *et al.* (1999), Stattersfield & Capper (2000), Stattersfield *et al.* (1998), Stuart & Hutton (1977), Stuart & Jensen (1981), Vincent (1935), van der Willigen & Lovett (1981), Zimmerman *et al.* (1996).

## Genus *ACHAETOPS* Roberts, 1922

### 306. Rockrunner

#### *Achaetops pycnopygius*

**French:** Achetopse à flancs roux **German:** Klippensänger **Spanish:** Saltarrocas de Damara  
**Other common names:** Damara Rockjumper

**Taxonomy.** *Sphenoeacus pycnopygius* P. L. Slater, 1953, Omaruru River, Damaraland, Namibia. Affinities uncertain. Often placed in genus *Chaetops* on basis of similarities in osteology and habitat, but entirely distinct in behaviour and voice; possibly does not belong in present family, and has been suggested, in part on basis of molecular evidence, that placement closer to sylviid genus *Sphenoeacus* more appropriate (although familial affinity of latter open to question). Further research required. Two subspecies recognized.

#### **Subspecies and Distribution.**

*A. p. pycnopygius* (P. L. Slater, 1953) – coastal SW Angola and N & C Namibia.  
*A. p. spadix* Clancey, 1972 – Huila and Namibe escarpment (SW Angola).

**Descriptive notes.** 16–17 cm; 24–34 g. Striking terrestrial babbler-like passerine, peppered black and white, with tawny rump and flanks and long dark tail. Male nominate race has crown to scapulars narrowly streaked buff and dark brown, diffusing on back to more vinous tints and on rump to tawny-chestnut; tail dark brown, flight-feathers dark reddish-brown with cinnamon fringes; long narrow supercilium buffy white, lores blackish, line behind eye blackish, ear-coverts dull cinnamon with white and dark streaks, narrow submoustachial stripe buffy white, narrow malar black; chin to upper belly buffy white, breast side with profuse

black spotting, lower belly to vent shading to bright tawny-rufous; iris dark brown; bill blackish, whitish base of lower mandible; legs dark grey to blackish-brown. Female is similar to male, but with more extensive tawny on belly. Juvenile is duller than adult, markings weaker, tail shorter. Race *spadix* is darker than nominate, darker on head and mantle, rump much darker, innermost tail feathers blacker. **VOICE.** Song, by both sexes at dawn and dusk, mainly in breeding season, a rich mix of clear bubbling and warbling notes, “tip tip tootle tootle ti tootle tootle too”, average duration in one case 2.2 seconds, in another 3.2 seconds, with pauses of 6–12 seconds between songs in bout; reported as sometimes mimicking other bird species. In territorial aggression a repeated soft “poew-perrit-poew”. Contact call “hoo-boy”; alarm a harsh “cheerrrrrrrr”.

**Habitat.** Sloping rocky areas, scree and outcrops with scattered thorn trees, especially along watercourses, in dry hills and mountains; rarely in trees, except when singing or calling in alarm. In Angola on rock-strewn moist grassy mountain slopes adjacent to and above escarpment forest.

**Food and Feeding.** Invertebrates, in one case apparently a small scorpion (Scorpiones); young provisioned with beetles (Coleoptera), green caterpillars (Lepidoptera) and grasshoppers (Orthoptera). Moves with tail frequently held cocked, often in open on rocks; has mouse-like running habit, and flies in laboured manner, with tail held downwards, cocked on alighting.

**Breeding.** Breeding-condition males in Dec in Angola; season Nov–Apr in Namibia. Solitary and territorial. Nest a large thick untidy structure of grass, outer rim of coarse dry blades, cup lined with fine soft grass and sometimes rootlets, well-matted entrance verandah-like; well hidden close to ground in middle of large clump of grass (e.g. *Digitaria dimeri*) or in low large-leaved shrub. Clutch 2–3 eggs, usually 3, pale pinkish-buff with dark brownish-red spots and slaty clouds; incubation period in one case 15 days; young leave nest at relatively early age, before able to fly, and hide in grass. Of five nests, three successful, each fledging 2 or 3 young (mean 2.3 per nest).

#### **Movements.** Resident.

**Status and Conservation.** Not globally threatened. Locally not uncommon in Namibia and drier coastal areas in SW Angola. Population in Namibia estimated at 96,000 individuals, of which 7500 in three protected areas, including Waterberg Plateau and Namib-Naukluft National Parks, where common. Regional population density variable, dependent mostly on elevation and rainfall; in Khomas Hochland, in C Namibia, densities higher on mica-schist than on granite slopes with less grass cover, fewer outcrops and small boulders.

**Bibliography.** Beresford *et al.* (2005), Clancey (1966, 1972a), Clinning & Tarboton (1972), Dean (2000), Fry *et al.* (2000), Ginn *et al.* (1989), Harrison *et al.* (1997), Hockey *et al.* (2005), Jarvis & Robertson (1999), Robertson *et al.* (1995), Stattersfield *et al.* (1998).

## Genus *CHAETOPS* Swainson, 1832

### 307. Cape Rockjumper

#### *Chaetops frenatus*

**French:** Chétopse bridé **German:** Kapfelsenspringer **Spanish:** Saltarrocas del Cabo  
**Other common names:** Rufous Rockjumper

**Taxonomy.** *Malurus frenatus* Temminck, 1826, Riviersonderend Mountains, Western Cape, South Africa.

Affinities uncertain. Recent biomolecular evidence suggests that this genus, rather than being included in present family, is more closely related to the picathartes (Picathartidae), but sufficiently distinct in structure, behaviour and breeding biology to merit placement in its own separate family, Chaetopidae. Further research needed. Commonly treated as conspecific with *C. aurantius*, but

## Genus *ARCANATOR* Irwin & Clancey, 1986

### 305. Dapple-throat

#### *Arcanator orostruthus*

**French:** Modulatrice grivelée **German:** Bülbültimalie **Spanish:** Tordina Manchada  
**Other common names:** Dappled (Mountain) Robin, Mottled Robin

**Taxonomy.** *Phyllastrephus orostruthus* Vincent, 1933, Mount Namuli, Mozambique. Affinities uncertain. Frequently placed in genus *Modulatrix*, but thought not to belong in present family; has been considered to be a bulbul (Pycnonotidae) or a chat (Turdidae), but recent molecular studies suggest that it is closest to the sugarbirds (Promeropidae). Further research needed. Three subspecies recognized.

#### **Subspecies and Distribution.**

*A. o. amani* (W. L. Slater & Moreau, 1935) – E Usambara Mts, in NE Tanzania.  
*A. o. sanjei* Jensen & Stuart, 1982 – Udzungwa Mts, in S Tanzania.  
*A. o. orostruthus* (Vincent, 1933) – Mt Namuli, in N Mozambique.

**Descriptive notes.** 17–19 cm. Dark greenish-olive babbler-like passerine with pale sulphur-tinted underparts heavily marked with soft-edged dark spots and streaks, very rounded wings. Nominative race has crown dark rufescent olive, face (lores, cheek and ear-coverts), neck side and upperparts dark olive, upperwing rufescent brown with paler fringes, tail chocolate-chestnut; chin, submoustachial area and throat pale yellowish with indistinct soft greyish-olive mottling, breast and flanks slightly stronger yellow with long, broad but soft-edged greyish-olive streaks, mid-belly pale yellowish with greyish-olive flecks, thighs and

vent unmarked pale yellow; iris brown or red-brown; bill blackish-brown, pale base of lower mandible; legs pinkish-grey. Sexes similar. Juvenile has little yellow on underparts, which appear rather uniformly olive. Race *amani* has crown, rump and flight-feathers without rufescent tinge, tail darker; *sanjei* is very like last, but has dark brownish-olive tail with minimal chestnut tinge, breast more heavily dappled, flanks more continuously dark olive, bill broader-based. **VOICE.** Song pure and pleasant but not rich, of several types, all rapidly delivered and of short, clear, melodious stanzas, sometimes like that of Old World oriole (*Oriolus*), e.g. “qu qu-we wurdilec wée-yew” or “(twee) turileá”, or “tu-tu-wéetaloo, tu-tu-wéetaloo”, or “tu-tupeeter-tu, ter-tu-wée”. Also has a bulbul-like melodious but repetitious chattering, “chiquea chiquea chiquea”. Main call a rising fluty whistle, “hoooo-reee”, ending much higher-pitched; at beginning and end of day a babble resembling sound of small bells.

**Habitat.** Undisturbed wet luxuriant montane evergreen forest, especially near streams, at 900–1800 m; 1500–1800 m on Mt Namuli; 1450 m to at least 1720 m in Udzungwa Mts, where it keeps to areas with scattered tall herbs and also places with open forest floor surrounded by dense patches of shrubs, herbs and *Cyperus*.

**Food and Feeding.** Invertebrates; stomach contents revealed insects. Terrestrial; forages invariably on ground. Tosses leaves in search of items. Rather territorial; keeps to an area even when subject to human disturbance (camping), but will leave if disturbance too heavy.

**Breeding.** Juv in Nov (E Usambara Mts) and breeding-condition bird in Nov, adult with brood patch in early Aug and another with brood patch in late Mar (Udzungwa Mts) in Tanzania; breeding-condition bird and one in apparent post-breeding moult in Nov–Dec in Mozambique. No other information.

#### **Movements.** Resident.

**Status and Conservation.** VULNERABLE. Restricted-range species: present in Tanzania–Malawi Mountains EBA. Rare to locally fairly common. Global population estimated at 10,000–20,000 individuals, within total geographical range of 6100 km<sup>2</sup>. Nominative race, although originally considered rare, is at least patchily numerous, with at least 2.5 birds/ha in one area, and likely total population in the low thousands; forest habitat in its altitudinal range, however, under increasing pressure from encroaching human population. Race *amani* is relatively rare, with population estimated at between a few hundred and a few thousand individuals (depending on degree to which it is restricted to Amani region); clearance of forest understorey for cardamom plantations in E Usambaras has created extensive areas uninhabitable by this species. Udzungwa race *sanjei* uncommon in Mwanihana Forest, but fairly common in S part of Udzungwa National Park, where 31 pairs/km<sup>2</sup>, and rather uncommon in remote wet luxuriant forest in the Ndundulu Range.

**Bibliography.** Benson & Irwin (1975), Beresford *et al.* (2005), Collier & Stuart (1985), Dinesen, Leimberg, Raboin & Fieldso (2001), Dinesen, Leimberg, Nylen & Jansen (1993), Fieldso (1999), Jensen & Bogger-Jensen (1997),

differs significantly in size, colour of underparts and extent of male's black upper breast; the two species approach each other geographically to within 100–150 km. Monotypic.

**Distribution.** Western Cape and SW Eastern Cape, in S South Africa.

**Descriptive notes.** 23–25 cm; 54–60 g. Striking ground-dwelling passerine, streaked grey and black above, with chestnut rump and underparts, black throat with white moustache, long and rounded white-tipped black tail. Male has crown, hindneck, upper ear-coverts, mantle, scapulars and back silvery grey with dense black streaks, rump rich chestnut, tail glossy black with increasingly broad white tips on outer feathers; upperwing-coverts black with white tips, flight-feathers black, outer primaries and inner secondaries tipped white, white patch at base of primaries; vague supercilium silvery grey, lores, cheek, lower ear-coverts, lower neck side and chin to upper breast black, submoustachial to upper breast side white, mid-breast to belly rich chestnut, vent and thighs blackish with buffy-grey tinge; iris orange-red; bill and legs black. Female is similar to male, but olive-brown replaces silvery grey above, rump and belly paler red, wings brownish-black, sides of face and neck buff-mottled grey-brown, submoustachial, chin and throat buff with dark grey-brown mottling. Juvenile resembles a weakly marked female. **Voice.** Song an often long series of penetrating piping notes, “psu-wee-psu-wee-psu-wee” and “sip-sip-psu, sip-sip-psu”, or more varied “peeup tri-tri-tri chi-treeecrip...”. Confrontations between territorial groups involve short piercing whistles. Monosyllabic contact and alarm calls; parent-offspring contact call a soft “cheee cheee chee-chee-chee-chee”.

**Habitat.** Rocky fynbos, from mountains down to sea-level, but particularly in windswept, high-rainfall areas on upper mountain slopes and ridges.

**Food and Feeding.** Invertebrates, occasionally small lizards and amphibians. Prey brought to nests at one site include caterpillars (30%), beetles (Coleoptera; 27%) and annelid worms, flies (Diptera), Hymenoptera, Orthoptera, spiders (Araneae) and scorpions (Scorpiones), less often geckos (Gekkonidae) and amphibians (*Brevicaps*). Forages on ground, probing with bill in sand around base of rocks and bushes, scuttling between patches of cover. Generally in pairs or family groups.

**Breeding.** Jul–Jan, mainly Sept–Oct. Breeds as monogamous pair in permanent all-year territory of 4–11 ha. Co-operative, with helpers. Nest, built by both sexes in 3–7 days, then lined added for 5–10 days before egg-laying; an untidy bowl of grass, twigs, rushes, lichen and moss, lined with fine grass, rootlets, hairy *Protea* seeds and mammal fur, placed on ground at base of rock or clump of vegetation, entrance oriented to protect against wind. Clutch 2 eggs, white, sometimes with reddish speckling; replacement clutches laid if first lost; rarely three attempts in season; incubation by both sexes (once by two females), period 19–21 days; nestling period 18–21 days (mean 19.5 days); young escape on foot but cannot fly for 5 days, with longer flights from day 10, fed by both parents and by any helpers present generally for 4–5 days but up to 30 days after fledging; of five ringed nestlings, three still on natal territories in following breeding season. Of 60 eggs (30 nests) at one site, 39 hatched, producing 24 young; losses due mainly to predation.

**Movements.** Resident; possibly some altitudinal movements.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Cape Fynbos EBA. Locally common. Potential threats include spread of exotic vegetation.

**Bibliography.** Beresford *et al.* (2005), Ericson & Johansson (2003), Ericson *et al.* (2003), Fry *et al.* (2000), Harrison *et al.* (1997), Hockley *et al.* (2005), Holmes *et al.* (2002), Macleod (1966), Martin (1964), du Plessis *et al.* (1995), Stattersfield *et al.* (1998), Winterbottom (1973).

## 308. Drakensberg Rockjumper

### *Chaetops aurantius*

**French:** Chétopse doré **Spanish:** Saltarrocas del Drakensberg  
**German:** Orangebrust-Felsenspringer  
**Other common names:** Buff/Orange-breasted Rockjumper

**Taxonomy.** *Chaetops aurantius* E. L. Layard, 1867, near Graaff-Reinet, west Eastern Cape, South Africa.

Affinities uncertain. Recent biomolecular evidence suggests that this genus, rather than being included in present family, is more closely related to the picathartes (Picathartidae), but sufficiently distinct in structure, behaviour and breeding biology to merit placement in its own separate family, Chaetopidae. Further research needed. Commonly treated as conspecific with *C. frenatus*, but differs significantly in size, colour of underparts and extent of male's black upper breast; the two species approach each other geographically to within 100–150 km. Birds in Lesotho reportedly paler below than those in rest of range, but no subspecies described. Monotypic.

**Distribution.** Lesotho highlands and adjacent South Africa in montane Free State, KwaZulu-Natal and Eastern Cape.

**Descriptive notes.** 21–22 cm; 48–53 g. Striking ground-dwelling passerine with long and rounded white-tipped black tail, similar to *C. frenatus*. Male has crown and upper face to upper back blackish with dense but narrow grey-brown streaks, lower back and rump chestnut, tail glossy black with increasingly broad white tips on outer feathers; primary coverts black, tipped white (forming patch on folded wing), flight-feathers brownish-black, white patch at base of primaries (visible in flight); narrow supercilium and broad submoustachial band white, upper ear-coverts rather plain grey, lores, cheek, lower ear-coverts, throat and upper breast black,

lower breast and belly sandy orange, colour most intense across breast; iris orange-red; bill and legs black. Differs from *C. frenatus* mainly in being smaller and smaller-billed, with underparts (but not rump) sandy orange (instead of chestnut), black of throat ending higher on upper breast, white supercilium more obvious, upper ear-coverts rather plain (not heavily streaked). Female is similar to male but usually paler above, throat mottled buffy white. Juvenile is like female but browner, less streaked

above, with bill paler. **Voice.** Song consists of series of various strident piping calls, notably a loud staccato “pree-pree-pree”, loud repeated “teep-teep-téep” and “pee-téé-teep”, sometimes in combination, very similar in tone and type to that of *C. frenatus* but distinct in structure; song often given simultaneously by group-members, and tail often fanned and depressed during singing. Male with nestlings gave repeated sharp piercing “pee” on descending scale, and harsh “churrrr”.

**Habitat.** Steep-sloping alpine and subalpine grasslands with rocky outcrops, scree, rocky gulleys and passes, but disappearing where extensive scrub cover and flat ground appear; mainly above 2250 m, but at 2000 m in KwaZulu-Natal and 1800 m in Eastern Cape.

**Food and Feeding.** Invertebrates, including caterpillars and moths (Lepidoptera) and grasshoppers (Orthoptera); nestlings fed mainly with caterpillars, but at one nest only grasshoppers. Forages on ground, pecking and scratching at earth, and bounding from rock to rock without flying. Usually in pairs or in family parties up to twelve individuals, but often dispersed widely when feeding.

**Breeding.** Jul–Apr, mainly Oct–Nov. Breeds as monogamous pair, in territory. Co-operative, with helpers. Nest, built by both sexes, a bulky, untidy deep cup, made mainly of grass with some twigs, lined with fine grass and rootlets, sometimes also mammal fur, typically just above ground under overhanging rock or shrub or in grass clump, especially wiregrass (*Merxmüllera*). Clutch 2–3 eggs, white, sometimes with black speckling; incubation by both sexes. No other information.

**Movements.** Resident or altitudinal migrant. Although reportedly resident in Lesotho, even above 3000 m, recorded also as making regular winter movements from 2500 m down to 2000 m along Lesotho–South Africa escarpment.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Lesotho Highlands EBA. Locally common; global population estimated at 100,000–500,000 individuals. Population in Lesotho estimated at 10,000–100,000 individuals, with density of 4 birds/km<sup>2</sup> in summer, 1.6/km<sup>2</sup> in winter; in summer, near Katse (Lesotho), average 1 pair or group/30 ha. Present in mid-winter in Mountain Zebra National Park, in Eastern Cape (South Africa).

## Genus MYSTACORNIS Sharpe, 1870

### 309. Madagascar Groundhunter

#### *Mystacornis crossleyi*

**French:** Mystacorne de Crossley **German:** Crossleytimalie **Spanish:** Tordina Malgache  
**Other common names:** Crossley's Babbler

**Taxonomy.** *Bernieria Crossleyi* A. Grandidier, 1870, Lake Alaotra, Madagascar.

Affinities uncertain. Appearance unlike that of a “true” babbler; has sometimes been placed tentatively in family Vangidae; further study required. Monotypic.

**Distribution.** E Madagascar.

**Descriptive notes.** 15–16 cm; 21–28.5 g. Small babbler-like passerine, olive-brown above and greyish below, with proportionately very long, narrow, slightly hook-tipped bill. Male has crown blackish-olive, with bluish-grey tinge laterally and on nape (all-over bluish-grey sheen in some lights); upperparts olive-brown, upperwing brown with paler olive-brown wing flash, tail rufescent brown; lores to above eye black, top and bottom of eyering white, upper ear-coverts glossy blackish-blue, lower ear-coverts black, submoustachial line under eye and ear-coverts to neck side white; chin and malar area to upper breast blackish-grey, shading

grey on breast, greyish-white belly and vent, dull ochreous-olive flanks and lateral undertail-coverts; iris dark brown to chestnut; bill black, lower mandible bluish or pale grey with black tip; legs pink. Female is like male, but crown as upperparts, tail less rufescent, lores, supercilium and upper ear-coverts mid-grey, chin and submoustachial area to mid-belly white, slight grey wash on breast. Juvenile is like female, but head chestnut, eyestripe black, neck chestnut, upperparts rufous, throat and underparts light chestnut, white centre of breast and belly. **Voice.** Song consists of three parts, a short, high-pitched, swelling “wee wee” (audible at close range), followed by prolonged, plaintive, resonant, sweet, melancholy, high-pitched whistle “tweeeeee” or “tsuuiooeeee”, and finally a harsh “tsishrrr”. Also has series of single-note whistles, “tooe tooe tooe”, sometimes given in rising series. Calls include very high “peeceer” and loud chacking in alarm.

**Habitat.** Primary broadleaf evergreen forest, also logged-over guava (*Psidium cattleianum*) forest, from sea-level to 1800 m.

**Food and Feeding.** Stomachs of three individuals contained spiders (of family Salticidae), cockroaches (Blattodea), earwigs (Dermaptera), bugs (Hemiptera, including homopterans), grasshoppers (Orthoptera) and ants (Formicidae). Found singly or in pairs. Walks or runs along ground, rarely flies; bobs head backwards and forwards when walking. Forages in open undergrowth and understorey of forest, among leaf-litter; also on or next to fallen trunks and rotten trees, probing mosses and epiphytes with bill.

**Breeding.** Aug–Nov. Nest, built by male, at least, a shallow cup or platform of largish twigs, sometimes fine black rootlets, lined with root-like material, or neatly woven grass and fern leaves, placed up to 1.5 m above ground in small tree, sessile pandan, or base of crown of tree-fern or on horizontal vines. Clutch 2–3 eggs, white, mottled with chestnut; incubation by both sexes. No other information.

**Movements.** Resident.

**Status and Conservation.** Not globally threatened. Fairly common to common throughout habitat, but patchily distributed; rarer in SE and at lower elevations. Present and fairly common in reserves at Périnet-Analamazaotra, Marojejy, Mantadia, Ranomafana and Andohahelo (parcel 1). **Bibliography.** Benson *et al.* (1977), Dee (1986), Goodman *et al.* (1997), Hartlaub (1877), Irwin (1983), Langrand (1990), Milne-Edwards & Grandidier (1881), Milon *et al.* (1973), Morris & Hawkins (1998), Rand (1936a), Safford & Duckworth (1990).

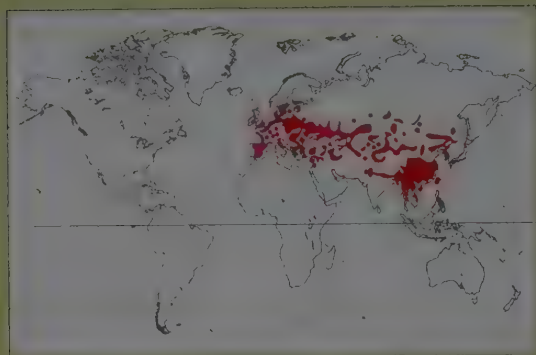

## Class AVES

## Order PASSERIFORMES

## Suborder OSCINES

## Family PARADOXORNITHIDAE (PARROTBILLS)

- Small passerines with strong arched bill, strong tit-like legs and feet, and longish tail; plumage mostly brown, grey and rufous in various combinations, often some black markings.
- 9.5-28.5 cm.

- Palearctic and Oriental Regions.
- Bamboo, grass, scrub and broadleaf evergreen forest, in lowlands and mountains.
- 3 genera, 21 species, 62 taxa.
- 3 species threatened; none extinct since 1600.

## Systematics

Apart from one or two of the 21 species, the parrotbills represent a relatively little-known group of Old World passerines. Their centre of distribution lies in central Sichuan, in China, where twelve species are found. From here, the ranges of the various forms radiate as far westwards as the Western Palearctic and Central Asia, where the widespread Bearded Parrotbill (*Panurus biarmicus*) occurs, and north to Mongolia, east to the south-east Russian region of Ussuriland, the Korean peninsula and Taiwan, and south to south-central Vietnam and east Cambodia, where the Black-crowned Parrotbill (*Paradoxornis margaritae*) has its very restricted range.

Historically, the parrotbills have been treated in various ways by systematists and taxonomists. E. W. Oates and W. T. Blanford, writing at the end of the nineteenth century, treated them as a subfamily of the crows (Corvidae). Later, in 1914, H. H. Harington included them in the babblers (Timaliidae). In 1922, E. C. Stuart Baker separated them as a distinct family, placing them between the tits (Paridae) and the nuthatches (Sittidae), the latter preceding Timaliidae in the sequence.

Recent research suggests that the parrotbills may not merit separation at the family level. Analyses of mitochondrial DNA by A. Cibois, with results published in 2003, indicate that, contrary to the 1990 classification by C. G. Sibley and B. L. Monroe, the babblers do indeed form a distinct family, and that the parrotbills belong therein. Nevertheless, for the present work their status as a separate family, Paradoxornithidae, is maintained.

As constituted herein, the family contains the three genera *Panurus*, *Conostoma* and *Paradoxornis*, the first two of which are monotypic. The third genus, *Paradoxornis*, has in the past sometimes been subdivided into several further genera. In this latter arrangement, the Black-breasted (*Paradoxornis flavirostris*), Spot-breasted (*Paradoxornis guttaticollis*) and Reed Parrotbills (*Paradoxornis heudei*) are retained in *Paradoxornis*, with the Three-toed (*Paradoxornis paradoxus*) and Brown Parrotbills (*Paradoxornis unicolor*) separated in the genus *Heteromorpha*, the Short-tailed Parrotbill (*Paradoxornis davidianus*) isolated in *Neosuthora*, the Grey-headed (*Paradoxornis gularis*), Black-crowned and Greater Rufous-headed Parrotbills (*Paradoxornis ruficeps*) combined in the genus *Psittiparus*, and ten of the remaining eleven *Paradoxornis* species placed in the genus *Suthora*.

In the light of the above, it is of additional interest that provisional DNA analysis suggests that the genus *Paradoxornis*, as

currently constituted, may not be monophyletic. One initial analysis-tree even indicates that certain "Suthora-type" parrotbills, namely the Short-tailed and Black-throated Parrotbills (*Paradoxornis nipalensis*), are more closely related to the timaliid Grey-headed (*Fulvetta cinereiceps*) and Golden-breasted Fulvettas (*Lioparus chrysotis*) than they are to the Grey-headed and Spot-breasted Parrotbills.

Some initial findings of more detailed ongoing genetic research specifically on parrotbills, being undertaken by C. Yeung and colleagues, suggest only a distant relationship between the Bearded Parrotbill and the other members of the family. Furthermore, it appears that the creation of at least two (possibly more) new genera of parrotbills may need to be considered, one for the Reed Parrotbill and the other for the Spectacled (*Paradoxornis*

The parrotbills are strictly Asiatic in distribution. The **Great Parrotbill**, the largest member of the family, is generally placed in the monotypic genus *Conostoma*. Its pale orange bill is longer than it is high, and proportionately much longer than the bills of most other parrotbills. Both sexes are grey-brown, with a flash of rufous on the inner wing and a whitish forehead. This species occurs in mountainous regions from north India to central China and Myanmar in open broadleaf forest, bamboo, and scrub, including rhododendron (*Rhododendron*).

[*Conostoma aemodum*, Wawushan, Sichuan, China.  
Photo: John & Jemi Holmes]

The genus *Paradoxornis* currently spans all but two members of the family, as well as a great deal of phenotypic variation. It can be divided into up to five subgenera, most of which may require separation at the genus level once well-sampled genetic analyses have been completed. One of these groupings is *Heteromorpha*, containing the **Three-toed Parrotbill** (*Paradoxornis paradoxus*) and the **Brown Parrotbill**. These species are large and drab, with subtle facial patterning and very stubby bills, greater in depth than they are in length. Like many parrotbills they are associated with bamboo at high elevations.

*conspicillatus*) and Vinous-throated Parrotbills (*Paradoxornis webbianus*).

At the species level, a number of modifications to the generally accepted taxonomy have been made since the mid-1990s. The recent separation of the Black-crowned Parrotbill from the Grey-headed Parrotbill has already been mentioned; this split was considered justified on the grounds of morphological and plumage differences, as well as vocal ones. Although T. Inskipp and colleagues in their 1996 *Annotated Checklist of the Birds of the Oriental Region* preferred to "lump" the Golden Parrotbill (*Paradoxornis verreauxi*) with the Black-throated Parrotbill, the two are very distinct morphologically from each other, and again treatment as two separate species does seem warranted.

Over the years, the dozen or so taxa making up the "the Vinous-throated Parrotbill complex" have been divided variously between two or more species. It now seems that three polytypic species, the Vinous-throated, Brown-winged (*Paradoxornis brunneus*) and Ashy-throated Parrotbills (*Paradoxornis alphonisianus*), are involved. All three have sometimes been regarded as conspecific. In 1991, following a detailed taxonomic study, Han Lianxian reported constant skeletal differences "in the shape of the lachrymal and orbital process of quadrates" between the Brown-winged and Vinous-throated Parrotbills, supporting the already widely accepted status of the two as separate species. The Brown-winged Parrotbill apparently has long, pointed lachrymals, which are roughly V-shaped, and the pointed socket of the inside of the quadrate is turned downwards. The Vinous-throated Parrotbill, on the other hand, has the lachrymal shorter and blunt, and U-shaped, and the sharp socket of the quadrate is not curved.

Where the range of the Ashy-throated Parrotbill meets that of the Vinous-throated Parrotbill, the two species can sometimes be found in mixed flocks, and hybrids between them have been recorded in these flocks, as, for example, near Sa Pa, in northernmost Vietnam. Apparent hybrids have been reported also in north-west Italy, where individuals of both species, released locally from captivity, have formed free-living populations in several areas (see Relationship with Man). Considering the level of association between the two, however, hard evidence of interbreeding is surprisingly scarce. From central China, there are several specimens considered to exhibit a range of intermediate features, and a separate report of interbreeding, both from central Sichuan and both in the first half of the twentieth century. It has been suggested that the race *ganluoensis* of the Ashy-throated Parrotbill is an intermediate form between this species and the Vinous-throated

Parrotbill, but this seems highly unlikely, as its range lies not within the overlap zone but, instead, to the west of that of the nominate race of the Ashy-throated; *ganluoensis* is thus closer geographically to the Brown-winged Parrotbill.

The Black-throated Parrotbill currently comprises a grouping of ten highly distinctive subspecies. Modern taxonomists would argue that these represent more than one species, and a simple division according to basic plumage differences would support the following five sibling species: the "Grey-capped Parrotbill", consisting of the nominate race and subspecies *garhwalensis*; the "Orange-eared Parrotbill", currently race *humii*; the "Grey-breasted Parrotbill", made up from races *poliotis* and *feae*; the "Buff-breasted Parrotbill", containing the taxa *ripponi* and *patriciae*; and the "Black-eared Parrotbill", represented by the current races *beaulieu* and *kamoli*. Examination of speci-

A group of ten species are sometimes separated in the genus *Suthora*. One of these, the **Black-throated Parrotbill**, is an exquisite little bird of montane forests. It forages in small energetic groups, like tits (*Paridae*), even hanging upside-down in a tit-like fashion. It has a highly fragmented population in Asian mountain ranges, providing a good example of the challenge and flux evident in avian systematics: regional forms are distinctive, and deeper analyses of molecular, morphological and vocal data will probably reveal that at least five species are involved.

mens in the Natural History Museum at Tring, in England, suggests that the tenth subspecies, *crocotius*, may be better regarded as representing a semi-stable hybrid population between *humii* and *poliotis*. "Typical" *crocotius* specimens are from Yonpu La, in east Bhutan, and Shakti, in extreme west Arunachal Pradesh; one from Yonpu La, however, shows a slightly closer resemblance to *humii* than do the others, and specimens from Deothang, to the south of Yonpu La, have more grey on the ear-coverts, suggestive of *poliotis*. Further, Black-throated Parrotbills from the Dafla Hills, several hundred kilometres east of Shakti and extending southwards into Assam, have been described as an additional subspecies, *daflaensis*, but this is currently treated as a synonym of *poliotis*; nevertheless, they appear to exhibit signs of intergradation with *poliotis*, rather than being identical with it, and are possibly better treated along with *crocotius* as a semi-stable hybrid population.

Finally, it is worth mentioning the taxonomy of the Reed Parrotbill, two subspecies of which are currently recognized. In 1979, L. S. Stepanyan proposed that the east Mongolian population represented a third form, which he named as *mongolicus*. This was said to differ from the subspecies *polivanovi*, which occurs in north-east China and Ussuriland, in adjacent south-east Russia, in having a slightly purer grey mantle lacking dark streaks, and a slightly darker back, rump and breast side. All of these characters, however, could be due to minor clinal variation. It was also suggested that *mongolicus* was slightly smaller. Almost 20 years later, in 1998, Stepanyan concluded that *polivanovi* was worthy of full species status, with *mongolicus* incorporated as a race of it, and that "*P. polivanovi*" formed a superspecies with a now restricted *P. heudei*; in this arrangement, the latter's range was that of the current nominate race, extending from south-east Shandong south in east China to north Zhejiang and along the lower Yangtze River.

Stepanyan's entire theory was based on a presumed "huge" gap between the northern and southern taxa. Since then, however, a number of Reed Parrotbill populations have been found in the intervening areas, and it is very likely that, in time, this species will prove to have a fully "joined-up" range. In addition, the possibility remains that the differences currently considered to characterize the subspecies *polivanovi* may represent no more than one end of a cline of geographical variation.

From the foregoing brief discussion, it is clear that the taxonomy of the parrotbills, at present treated as 21 species within a single family, the Paradoxornithidae, will almost certainly undergo radical modification in the not too distant future. In the meantime, however, it is probably more helpful to maintain the existing arrangement while field and laboratory research continues.

## Morphological Aspects

More than 80 years ago, Stuart Baker stated that the parrotbills differ from the babblers simply in having the nostrils completely covered by bristles. The bill is very deep, being greater in depth than in length, except in the case of the two monotypic genera *Panurus* and *Conostoma*. The culmen is strongly downcurved, and the mandibles of most species have the edges at least wavy in shape or even S-curved. The bill bears a resemblance to those of parrots (Psittacidae), hence the English name of "parrotbill". The nostrils are circular, and are shielded by plumules or, in the case of *Panurus*, by a coriaceous membrane. All parrotbills have typically short and rounded wings, and the flight is rather weak and direct.

Parrotbill plumages are mostly brown, grey and rufous in various combinations, often with some black markings. With a single exception, the sexes of parrotbills are alike. Indeed, they are very difficult to tell apart, even in captivity, except perhaps by their behaviour during the breeding season.

The only sexually dimorphic member of the family, the Bearded Parrotbill, has a bill that is not parrot-like but is relatively long and pointed. The culmen and the cutting edges are gradually decurved towards the sharp tip. The nostrils are small, narrow, and partly covered by a membrane above; they are partially hidden under hair-like bristles projecting from the bill base. The tail is long and graduated. The male is rather attractive, having a grey head with a characteristic broad, long black "moustache"; it is otherwise essentially light rufous-chestnut above and white to creamy below, becoming pale vinous-pink on the belly sides, with darker flanks and vent and black undertail-coverts. The female, in contrast, is drab brown from the forehead to the nape, with pale grey confined to the rear side of head, and without the distinctive moustache of the male; she is also somewhat duller above and duller and paler below. Both sexes have dark brownish-grey to greyish-black wings, with a distinct white panel formed by the outer fringes of the outer primaries and their coverts, bordered by a rufous panel created by the edges of the median and greater upperwing-coverts.

The other monotypic genus contains the Great Parrotbill (*Conostoma aemodium*). This is, as its name suggests, much larger than the other parrotbills, and it has a less graduated tail. The outermost pair of rectrices is about three-quarters of the total length of the tail. The bill is longer than it is high, and is proportionately much longer than that of other parrotbills, with the possible exception of the Bearded Parrotbill. Both males and females are grey-brown, with a whitish forehead.

*Paradoxornis* parrotbills, a total of 19 species in the current treatment, are probably best dealt with as five separate groups. The subdivisions of this genus, whether or not they are accorded taxonomic significance (see Systematics), do exhibit several features by which they may be recognized. Thus, the three "typical" *Paradoxornis* species, namely the Black-breasted, Spot-breasted and Reed Parrotbills, have a more graduated tail than that of the Great Parrotbill, with the outer feathers not more than two-thirds of the total tail length. In addition, the bill is much shorter and deeper; the cutting edge of the upper mandible has a deep S-shaped curve, and there is a corresponding curve in the lower mandible. The large and drab-coloured Three-toed and Brown Parrotbills are similar to the three aforementioned "typical" species, but with overall plumage resembling that of the Great Parrotbill. They are sometimes placed in a separate genus, *Heteromorpha*.

Members of the third group, the ten species which are sometimes united in the genus *Suthora*, have a tail that is long and graduated, the outer rectrices being about half the length of the central ones. The bill is short and thick, slightly longer than it is

Three species are sometimes separated in the genus *Psittiparus*. The **Greater Rufous-headed Parrotbill** is typical of this group in having the tail roughly equal in length to the wings and barely graduated, with the outermost feathers almost as long as the central ones. Its legs are exceptionally strong, an adaptation which allows it to forage acrobatically in patches of bamboo, a substrate it rarely abandons. Its global distribution extends from the Himalayas to the Annamite range of Laos and Vietnam.

[*Paradoxornis ruficeps*,  
Namdapha National Park,  
NE India.  
Photo: Ketil Knudsen]

The **Bearded Parrotbill**, a reedbed specialist, has a relatively long pointed bill, and a graduated tail. The male is rather beautiful, with soft plumage and a characteristic black "moustache" on a grey head. It is otherwise essentially rufous-chestnut above and creamy white below. The female, meanwhile, is mainly drab brown, lacking the male's distinctive moustache. Both sexes have dark wings, with a distinct white panel formed by the outer fringes of the outer primaries and their coverts, bordered by a rufous panel created by the edges of the median and greater upperwing-coverts. This species is an outlier in the family, and therefore always separated in the monospecific genus *Panurus*. Not only is it the only sexually dimorphic parrotbill but it is also the only one to have expanded its distribution westward to Europe. Furthermore, it is the only one with a bill that bears no resemblance to that of parrots. Its taxonomic relationships and evolutionary origins have puzzled ornithologists for over two centuries, resulting in considerable nomenclatural instability. The traditional name of "Bearded Tit" made way for "Bearded Reedling", which in turn has been replaced by Bearded Parrotbill. Indeed, this name is not assured any permanence either because, according to molecular evidence, even the link with parrotbills may be remote.

[*Panurus biarmicus*  
*biarmicus*,

deep, and with almost straight cutting edges. The nostrils are very small, circular, and completely concealed by plumules. These species have legs that are long in proportion to the body size, and they climb in a tit-like fashion, but also bounce between perches, and frequently hang upside-down. The ten species are the Spectacled, Vinous-throated, Brown-winged, Ashy-throated, Grey-hooded (*Paradoxornis zappeyi*), Rusty-throated (*Paradoxornis przewalskii*), Fulvous (*Paradoxornis fulvifrons*), Black-throated, Golden and Lesser Rufous-headed Parrotbills (*Paradoxornis atrosuperciliaris*).

One species, the Short-tailed Parrotbill, is the sole member of the "*Neosuthora* group". It has a tail that is less graduated and much shorter than that of other parrotbills, a bill that is proportionately larger and much deeper, and wings that are even more rounded. These characters, in combination, lend it an appearance

like that of a munia (*Lonchura*), a member of the family Estrildidae. This is the only parrotbill having the tail shorter than the wing.

The fifth block, the "*Psittiparus* group", contains the Grey-headed, Black-crowned and Greater Rufous-headed Parrotbills. These have the tail about equal in length to the wing, and hardly graduated, with the outermost feathers about five-sixths the length of the central ones. The legs are exceptionally strong.

Adult parrotbills undergo one complete annual moult, a post-breeding moult in the autumn. Juveniles typically moult into full adult plumage during the first autumn of their life.

### Habitat

In the minds of the majority of ornithologists, parrotbills are associated with bamboo, and, indeed, ten of the 21 species are primarily inhabitants of bamboo. Three species are associated with other types of grasses, including reeds. The remaining eight prefer secondary woody vegetation or open forest, but can occur in bamboo. The Vinous-throated Parrotbill and its close relatives occupy the widest range of habitats, having become adapted to occur in all kinds of marginal vegetation, such as secondary growth, scrub, hedges, bamboo groves, marshes, reedbeds, plantations, nurseries and the like. At the other end of the spectrum, the Grey-hooded Parrotbill is found only in bamboo and bushes in open mountain-top conifer forest and mixed fir (*Abies*) and rhododendron (*Rhododendron*) forest, the Bearded and Reed Parrotbills are very much restricted to reedbeds, and the Black-breasted Parrotbill is restricted to tall grassland.

Among the bamboo-loving species, the Three-toed, Fulvous, Short-tailed, Lesser Rufous-headed and Greater Rufous-headed Parrotbills, at least, rarely stray from this habitat. Of these five, the last two can often be found in consort with other bamboo-dependent species, such as the White-hooded (*Gampsorhynchus rufulus*) and Collared Babblers (*Gampsorhynchus torquatus*).

The altitudinal range occupied by the parrotbill family is a wide one, extending from sea-level up to an elevation of about 3660 m. The more lowland species are those associated with blocks of reeds and tall grassland, although the reedbed-dwelling species can sometimes be found at higher altitudes, as high as the limit of occurrence of suitable habitat within their ranges. The Bearded Parrotbill, for example, ascends to at least 3050 m. The species found within the broadest altitudinal zone is the Vinous-throated Parrotbill, which, in Taiwan, has evolved through limited competition to occupy areas from sea-level up to 3100 m. Indeed, it is thought probably to have the widest niche of any

The juvenile **Bearded Parrotbill** resembles the adult female, apart from several morphological peculiarities. It is more buff, and less chestnuttinged, and its lower mantle, back and outer rectrices are blacker. The immature male—pictured here—is duller overall than the adult male, lacking the vinous-pink tinge to the underparts, and having the black "moustache" restricted to the lores. The iris in juveniles is murkier than that of adults, becoming progressively lighter, and approaching light yellow to orange around the time of the juvenile moult.

[*Panurus biarmicus russicus*, Hungary.

Photo: Markus Varesvuo]

Signalling behaviour in parrotbills is poorly known. Given their group-living habits they must have developed subtle signals to mediate within-group and between-group conflicts, but virtually nothing has been written about their vocalizations and displays. This **Golden Parrotbill** is calling insistently while raising its spread tail, and fluttering its open wings. Whether the context and function of this behaviour is related to courtship or conflict is unknown. Parrotbill displays are probably babbler-like, and especially similar to group-living babblers.

[*Paradoxornis verreauxi*, Wawushan, Sichuan, China.

Photo: Nick Athanas]

Most parrotbills are distinctly gregarious. In the **Bearded Parrotbill** this is a seasonal feature, with breeding pairs and post-breeding families coalescing in the non-breeding season to form monospecific flocks. These gatherings vary in size and composition, containing up to 40–50 individuals, or even 200 at certain localities. These gatherings roam across major reedbeds during the winter months, before disbanding for the breeding season in February and March.

Denzau]

bird species in Taiwan. Those with the most restricted elevational ranges are, not surprisingly, all montane species. These are the Rusty-throated, Grey-hooded and Brown-winged Parrotbills, which live within altitudinal limits of, respectively, 2440–3050 m, 2350–3437 m and 1525–2800 m.

### General Habits

Several traits that are typical of timaliid babblers have been noted in the behaviour of the parrotbills, thereby reinforcing the view that the latter are, in fact, true babblers (see Systematics). These aspects of behaviour include the use of the feet during feeding, and the habits of allopreening, clumping in groups, and “in-out bathing”.

In general, parrotbills are very gregarious, and several species often associate with other relatively small passerines, including certain babblers, in mixed foraging flocks, commonly referred to as “bird waves”. Bearded Parrotbills occur in pairs and family parties, and after breeding form flocks of up to 40–50 or even, on occasion, 200 or so individuals. They remain in groups of varying size and composition during the winter months, before breaking up during February and March.

Social organization and flock dynamics of Vinous-throated Parrotbills have been studied in South Korea and Taiwan. In South Korean studies, it was confirmed that flock size changes seasonally. Flocks gradually increased in size from August onwards, with large parties of 100–140 individuals often observed during October–January. They were then noted as gradually decreasing in size from January onwards, with no large aggregations recorded after February. The flock size was characterized as small in April–July, medium-sized in August and September, large in October–January, and middle-sized again in February and March. Food quantity was the main factor governing the daily routine of flocks. During the non-breeding season, two kinds of flocks, termed “main flocks” and “peripheral flocks”, were noted in South Korea. Main flocks were considered to be larger and to have a defined home range, such as along a stretch of stream.

Members of winter flocks in Taiwan were classified in four categories: (1) core members, which never changed flocks; (2) regular members, which remained primarily in one flock, but visited or temporarily joined neighbouring flocks; (3) floaters, which moved among flocks, instead of having a long-term affiliation

with any specific one; and (4) peripheral members, which were seen in no more than two months in each year, these presumably being visitors from flocks outside the study area.

The ranges of different main flocks can overlap with one another, and two flocks have been observed to forage close together without merging. As they approached each other, it was noted that there was often great excitement and loud contact calling. Typically, when “main flocks” come close to each other or meet, they part quickly, without any transference of individuals, and without any signs of aggression or territorial behaviour. In Taiwan, when two flocks of Vinous-throated Parrotbills merged, a period of loud chorusing ensued, and the groups were seen to stay together for more than two hours, feeding and calling, before separating again.

Movement of an individual from one flock to another was noted in Taiwan as being of two types. The first involved temporary visits, and the second was a more permanent move lasting for more than two months. Temporary changes occurred when a parrotbill was accidentally left behind when a flock moved on, or when two flocks separated after having met. The individuals involved in these cases normally returned to their home flock shortly after the encounter. As many as 45–48% of individuals changed flocks during a three-year survey. The highest number of such changes made by an adult in one year was nine, and that of a juvenile was six. It has been suggested that inter-flock encounters and the switching of flock membership could be mechanisms that have evolved as a means of decreasing the likelihood of inbreeding. In South Korean studies, just a few individuals, having been initially identified as members of one flock, transferred to other flocks during October–January.

During a seven-year study in Taiwan, it was found that a Vinous-throated Parrotbill flock was composed primarily of the members of one or two extended families, spanning up to three generations, along with some individuals of unknown lineage. Furthermore, there was a remarkable similarity in the age composition of different flocks within a year, even though the age composition of the population as a whole differed from one year to another. Flock-leaders were not identified during Korean studies of Vinous-throated Parrotbills, nor was there any obvious evidence of aggressive behaviour between different pairs or individuals, or any social hierarchy.

Individual Vinous-throated Parrotbills that forage together during the day usually roost together, and neighbouring flocks

can also share the same roost. Most flocks of this species roost in specific areas at night, and flock-members separate into small clusters of individuals and spread out into suitable locations. Upon nearing the roost-site, they slow down, move to the lower vegetation level, and slowly hop towards the roost.

Bearded and Vinous-throated Parrotbills, two of the better-studied members of the family, are generally considered to be very weakly territorial. The main type of territorial behaviour appears to involve "supplanting", whereby an individual displaces an intruder of the same species by approaching it or sitting on a nearby perch. During the early part of the breeding season in South Korea, males were seen to drive away other parrotbills that were following them and their partner, and females were observed to supplant intruders. Fighting between pairs or individuals has not been observed in the wild. In captivity, breeding males of the Vinous-throated Parrotbill are considered to be bolder and more aggressive towards other species than are the females. Females are considered to be relatively constant in this respect throughout the year, usually watching or following the male. The minimal aggression that Vinous-throated Parrotbills exhibit is further evidence of their need for energy conservation (see Food and Feeding).

During studies of Vinous-throated Parrotbills, the birds were observed to be in pairs from March to August, corresponding with the breeding period, and pairs apparently form only after the break-up of winter flocks. During a two-year survey in South Korea, 78% of pairs consisted of individuals which were members of the same winter flock. During the early part of the breeding season, in March and April, some pairs were seen to feed away from their small flock during the daytime, returning to it before dark. Some pairs that had already built nests were still occasionally associating with the flock in April. Pairs typically breed within the home range of the particular flock to which they belong, but pairs consisting of individuals from two different flocks have also been recorded. Breeding-season studies in South Korea revealed that isolated single pairs were not unusual, but there were usually at least two or more pairs in close proximity (see Breeding).

Juvenile dispersal by the Vinous-throated Parrotbill has been studied. In South Korea, of 98 individuals of this species marked as nestlings, 16 were recaptured during July and August, but none in September, and it was considered that juveniles travelled far from breeding sites, and did not join the main non-breeding flocks

in the study area. On the contrary, many juveniles from nests outside the study area gradually joined flocks which also included birds that bred within their wintering ranges. In Taiwan, however, most juveniles, 66–96% in various studies, remained and bred in the parental flock, while the rest moved to neighbouring flocks, the discrepancy between the two regions perhaps reflecting differences in the study areas. The chances of breeding for a young bird seemed not to be influenced by whether or not it left its parental flock.

"High-flight" (see Movements) by Vinous-throated Parrotbills is apparently very rare and is thought probably to be a prelude to either eruptive behaviour or pair formation. Fledged young of the Bearded Parrotbill form pairs soon after independence, although it is not known whether these bonds are maintained up to the first breeding season, and they also congregate in flocks at this time. It

Many forest-based parrotbills live in permanent groups. The **Fulvous Parrotbill**, for example, travels in small parties all year round, although groups can swell to 30 individuals in the non-breeding season. These groups sometimes associate with foraging flocks containing other understorey bird species, especially babblers (Timaliidae). The factors underlying group composition in parrotbills are unknown, but flocks in at least one species contain the members of one or two extended families, spanning up to three generations, along with individuals of unknown lineage.

[*Paradoxornis fulvifrons* cyanophrys, Wawushan, Sichuan, China.

Photo: Christian Artuso]

Parrotbills frequently indulge in mutual preening, or allopreening. This is typically a form of mutual comfort behaviour undertaken by paired individuals, and is thought to enhance pair cohesion. The behaviour is perhaps even more regularly observed in group-living species, such as the **Spot-breasted Parrotbill**, but it is not known whether it is only undertaken by paired birds within the group. Allopreening, group-living, the use of feet during foraging, and "in-out bathing" are all forms of behaviour that link parrotbills to the timaliid babblers.

[*Paradoxornis guttaticollis*, Mt Victoria, Myanmar. Photo: Rob Hutchinson]

The **Bearded Parrotbill** switches seasonally from a vegetarian to a non-vegetarian diet, with interesting repercussions for foraging behaviour and digestive adaptations. In winter, it subsists on a diet of reed seeds, which it extracts by drawing parts of reed-heads through the bill while nibbling rapidly, as shown here. To digest these seeds the stomach develops hard plates and is filled with tiny stones. In spring these stones are excreted, and in summer the species captures adult and larval insects by snatching and flycatching at any height from the water's surface to the reed-heads. During this season the stomach is smaller and softer, with relatively few stones.

has been suggested that the initial pair formation by juveniles might ensure that erupting groups, on arriving at their destination, contain an equal sex ratio. The flocks of juveniles are joined by adults once the latter have finished their breeding activities.

Parrotbills are seldom seen to fly for long distances. Even so, the Bearded Parrotbill, which has a rapid and direct flight style, can be seen to cover considerable distances over reedbeds. The flight of this species has been described as being rather mechanical, with whirring wingbeats, and often a strange "winding" movement of the tail, during which it is fanned and then suddenly twisted; the effect is that of level or slightly undulating but uneven flight progress.

Groups of Bearded Parrotbills roost in rows, each in physical contact with its neighbour, on reed stems. Mutual preening and head-scratching have been recorded for this species.

## Voice

The wide variation in morphology, biology and habitat requirements among the parrotbills is reflected also in their vocalizations.

The Bearded Parrotbill has a simple song of about three notes, as well as clear, loud ringing call notes. The Great, Three-toed and Brown Parrotbills, on the other hand, utter rather loud, clear and relatively well-phrased songs, consisting usually of up to four notes. The typical call notes of the first of these three species are wheezing, squealing, cackling and churring notes, whereas the Three-toed and Brown Parrotbills emit guttural calls, short shrill whining sounds and harsh crackling calls. The vocalizations of this trio are perhaps more like those of laughingthrushes (*Garrulax*) than those of other parrotbills.

Both Grey-headed and Greater Rufous-headed Parrotbills also have relatively well-structured songs, that of the latter species being particularly varied, jolly and emphasized. Both species give distinctive "jiow" and "jieu" call notes, those of the Greater Rufous-headed Parrotbill being somewhat louder and more clearly audible. In addition, the Grey-headed Parrotbill, when alarmed, utters harsh scolding rattles like those of a scimitar-babbler (*Pomatorhinus*), and the Greater Rufous-headed Parrotbill, in a similar context, emits a highly distinctive loud, metallic spluttering rattle resembling the sound made by a machine-gun.

Black-breasted, Spot-breasted and Reed Parrotbills have songs that are made up of variable series of clear, quite high stac-

cato notes. The songs of the two first-mentioned species are, unsurprisingly, very similar to one another, and both have a varied repertoire of songs of 3–7-notes and similar calls. The corresponding vocalizations of the Reed Parrotbill are equally varied, although often consisting of more notes. No obvious non-contact-type call notes have been recorded from Black-breasted and Spot-breasted Parrotbills, whereas the Reed Parrotbill may utter a subdued "jhew-jhew" or "jhjo-jho", reminiscent of certain calls of some other larger parrotbills.

In general, the *Suthora*-type parrotbills (see Systematics) utter short high-pitched songs, and have jumbled chattering flock-calls mixed with higher notes. The Lesser Rufous-headed Parrotbill has been recorded as giving varied series of rapidly repeated sharp chipping notes, but it is not clear at present whether this is the song. This species also emits subdued but rapid, jumbled, chattering call notes interspersed with harsher, more metallic notes. The songs of the Spectacled, Vinous-throated, Ashy-throated and Fulvous Parrotbills all consist of a series of 2–5 quickly delivered thin, high, often piercing notes, preceded, in the case of some species, by weak introductory notes. The songs of the Brown-winged and Rusty-throated Parrotbills are currently unrecorded, but they are likely to be very similar to those of the previous four species. The typical non-contact-type call notes of the Spectacled Parrotbill are slightly buzzy and mechanical-sounding, those of the Vinous-throated Parrotbill consist of subdued rapid chattering and chuntering mixed with thin, high piercing notes, and those of the Grey-hooded Parrotbill are harsh, abrupt, scolding, rather rasping sounds; the corresponding calls of the Rusty-throated Parrotbill are rather harsh, spluttering, rolling notes mixed with more tit-like calls, and those of the Fulvous Parrotbill are subdued and slightly spluttering.

Black-throated and Golden Parrotbills have strange, extended, high, wheezy, buzzy, nasal songs of 2–6 notes, but they also give extremely high, thin, steadily rising secondary-type songs of 2–4 notes which bear more resemblance to the songs of the other species in this *Suthora* grouping. These two species utter short rattles and quite harsh, low, slightly spluttering call notes, as well as scolding squeaky nasal call; some of the vocalizations of Golden Parrotbills, at least, are strongly reminiscent of certain ones uttered by the Golden-breasted Fulvetta, a typical timaliid babbler. Generally, the members of the *Suthora* group (see Systematics) give harsher more scolding call notes when agitated.

The **Ashy-throated Parrotbill** travels in parties of 10–40 individuals in the non-breeding season, foraging mainly on seeds and buds, although it may search for insects, if available. During the breeding season, the insect component increases, making up most of the food provisioned to nestlings. Insects are caught in a relatively sluggish manner by examining foliage and plucking off slow-moving forms such as larval lepidoptera or adult orthopterans. This species occurs in south China and north Vietnam, while a small population founded on escaped cagebirds is now established in Italy.

[*Paradoxornis alphonsianus*  
*alphonsianus*,  
 Bifengxia, Yaan,  
 Sichuan, China.  
 Photo: John & Jemi  
 Holmes]

The Short-tailed Parrotbill delivers a series of 6–9 very thin, high, rapid, ascending notes, and it also gives a more structured, three-stage secondary-type song. Jumbled twittering can often be heard from flocks of this species, which also emits harder, shrill, stressed series of short tit-like notes that probably function as alarm calls.

Finally, it may be mentioned that the vocalizations of the Bearded Parrotbill are, as one might expect, thought to be important for the cohesion of groups, especially during eruptive activity (see Movements). It is likely that the same applies to other species in this family.

## Food and Feeding

Parrotbills feed primarily on insects and spiders and on vegetable matter, especially seeds. Of particular interest is the Bearded Parrotbill, which adapts its diet according to the season. During the winter months, its stomach develops hard plates for digesting seeds and is filled with small stones, which are excreted in the spring. Fewer and larger stones are then ingested, and in the summer the stomach is smaller and softer, with few or no stones. Young Bearded Parrotbills, prior to fledging, are fed solely on a non-vegetarian diet.

This is a relatively agile species, hopping and jumping along reed stems, straddling more than one stem, and undertaking acrobatic movements while feeding on seeding reed-heads. It has been observed to draw parts of reed-heads through its bill while nibbling to extract seeds. It also hops, jumps and creeps over ground-level debris and mud. The Bearded Parrotbill is not capable of breaking open reed stems, but it pecks at the surface of these and at cracks in it, as well as at broken reed stems. It also scratches and probes the ground, digs holes in snow, turns over reed leaves, and makes short-range flycatching sorties from the tops of reeds.

It has been noted that, in captivity, Vinous-throated Parrotbills strip bamboo in search of grubs, and seldom attempt to catch flying insects, although they will take a moth (Lepidoptera) that has become trapped, and readily pick fruit flies (Drosophilidae) from flight wires, foliage and fruit-fly feeders. When eating large

grubs such as mealworms, in the form of larvae of the darkling beetle (*Tenebrio molitor*), and waxworms, the larvae of the greater wax moth (*Galleria mellonella*), they stand on the grub's tail and pull its head with the beak until the internal soft tissue is removed.

Wild-living Vinous-throated Parrotbills, in Taiwan, feed mainly on seeds, flowers, fruits and buds, insect food constituting only about 37% of the diet. They are primarily understorey-dwellers, but will visit the canopy of relatively small trees in search of certain flowers and seeds. During the period from December to March, lantana (*Lantana camara*) and the grass giant miscanthus (*Miscanthus floridulus*) were the most important species influencing habitat use by parrotbills in Taiwanese studies, although the importance of each of these varied from month to month. A plant species apparently became more popular when it was the most abundant food source in the habitat. It is thought that parrotbills keep fairly good track of the quality and quantity of plant foods in their habitat. Vinous-throated Parrotbills favoured an inter-branch distance on shrubs of 6–13 cm, and especially 6–7 cm. This is regarded as a relatively long distance, but one that can be covered in an easy hop, while shorter distance between branches may prove more difficult because of the typical gait of the bird. The parrotbills zigzag through their habitat, making detours to avoid crossing wide open spaces, and they often follow dense vegetation to a point where a narrower gap can be found before crossing from one patch of cover to another. Before crossing a gap of more than 5 m, the individuals at the front of a flock tend to call and to wait until those behind them catch up, and only then move across the opening.

Parrotbills evidently make decisions on habitat use which take into consideration the travelling "costs" within each habitat. Thus, the conservation of energy seems to be a primary concern for flocking parrotbills, and local vegetation structure or other habitat features can influence the amount of energy expended during foraging. Both the tracking of food abundance and the minimizing of travelling cost must have the effect of maximizing the energy return, and parrotbills concentrate on favoured areas having a high food supply, where the amount of energy that needs to be expended is not too great. Activity levels remain stable throughout the day, even during light to medium rainfall. Vinous-throated Parrotbills forage almost continuously during the day,

except for some short bouts of resting, bathing or preening. There are no clear early-morning and late-afternoon peaks in feeding activity. In Taiwan, this species, when awake, spent 85% of its time foraging or feeding.

Perhaps the most unusual observation of parrotbill feeding behaviour involved a Great Parrotbill in western China. Here, an individual of this species was seen to catch and carry off an adult Buff-barred Warbler (*Phylloscopus pulcher*), presumably to feed to its young.

### Breeding

Most of what is known about the breeding of this family relates to the two best-studied species, the Bearded and Vinous-throated Parrotbills.

Both of these species are monogamous, although bigyny has been reported for the Bearded Parrotbill. Little information is available on the courtship display and copulation behaviour. During the late winter, flights over reedbeds by male Bearded Parrotbills, as well as aggressive interactions between males and a reduced tolerance of females towards each other, are thought to relate to pair formation. During the winter and spring months, individual Vinous-throated Parrotbills in South Korea were occasionally seen to separate temporarily from their flock and fly up to the higher branches of a tree, while being pursued by one or more others of the species. Other courtship behaviour by this species involved short flights between perches, and a fluttering descent to the same or another perch. After these brief courtship pursuits, pairs would return to their flock. The courtship display of the male Bearded Parrotbill accompanies a three-note song; on the second note the bird stretches its head and neck slightly up, and on the third note it lowers its head, with the feathers ruffled, until its bill touches its breast.

Independent juvenile males of the Bearded Parrotbill, in aggressive confrontations with one another, ruffle up their back feathers, fan the tail and lower the head, and in this posture they run, with a stiff-legged gait, beside one another. Males occasionally display to females in a similar manner. Another display, by recently fledged juveniles, is thought to be related to early pair formation, and involves a male hopping beside a female while holding his tail fanned and twisted so that the undertail-coverts are exhibited to her.

Once Vinous-throated Parrotbills have formed pairs, the partners typically stay close together, except during the incubation period, and the male practises "mate-guarding", whereby he protects his mate from the attentions of other males simply by remaining close to her. During extensive work on Vinous-throated Parrotbills, only rarely has copulation been observed. This is thought to be due to the fact that, during the breeding season, pairs are rather secretive and spend their time in relatively dense vegetation, where they mate close to or on the ground. Copulation has been observed three times in South Korea, on each occasion lasting 2–5 seconds. On two of these occasions it took place on the ground, and in the third instance close to it. In one case it followed display, during which the male hopped next to the female, fanning and twisting his tail, and then flew jerkily for about 5 m. Females were noted as exhibiting evasive behaviour, and apparently did not allow copulation to take place without resistance.

Copulation by Bearded Parrotbills is apparently not preceded by a display, although the male hops towards the female while calling and raising his wings. During the initial stages the female behaves in an evasive manner, but later she is chased and then "raped". After the nests have been built, female Bearded Parrotbills permit copulation without resistance. The act of mating by this species also takes place on or near the ground, but it has been recorded as lasting for approximately 15 seconds. A

Several species of parrotbill, including the **Grey-headed Parrotbill**, are known to feed on very varied plant matter, including chestnuts, buds, seeds and fruit. A large item is removed and carried to a convenient twig, where it is held with the feet, in the manner of a tit (*Paridae*), and eaten piece by piece.

The Grey-headed Parrotbill is essentially a forest bird, and is much more arboreal than most of its relatives, although it sometimes drops to the ground to feed. It lives in small groups of 6–8 individuals, sometimes up to 30 or more, which often associate with babblers (*Timaliidae*) and other passerines in mixed flocks.

[*Paradoxornis gularis*.  
Photo: Cyril Laubscher]

The **Bearded Parrotbill** spends much of the time at the bases of reeds. It regularly drops to the ground, where it hops, jumps and creeps over debris and mud, pausing to scratch and probe the surface of the ground and to turn over reed leaves. It even digs holes in snow to get at the food items hidden beneath. With a dextrous grip of reeds, and manoeuvrable legs, it can easily cling low above water to take a drink, as demonstrated here.

[*Panurus biarmicus*  
*biarmicus*,

Photo: Markus Varesvuo]

In most parrotbill species, both sexes contribute to nest-building, incubation and chick rearing. Adult parrotbills eat a mainly vegetarian diet based around seeds and fruit, but young birds prior to fledging tend to be fed a non-vegetarian diet. Thus, this male **Bearded Parrotbill** is carrying a fresh load of insects back to its brood. Many granivorous or frugivorous bird species bolster the nestling diet with animal matter in this way, presumably because of the greater returns it offers in energy, protein and water content.

recent study of sperm use by Bearded Parrotbills demonstrated that females copulated at a higher rate with their partner when other males were present, but that this did not translate into more sperm on eggs, possibly because insemination rates exceeded the female's sperm-storage capacity. It appears that this species copulates frequently because a single insemination is not enough to fertilize the entire clutch, and females have to continue to copulate during the egg-laying period in order to avoid the risk of their eggs being infertile.

Bearded and Vinous-throated Parrotbills tend to breed in concentrations of several pairs. Although isolated single pairs of the former are not rare, there are usually at least two pairs close together. In addition, there is a tendency for smaller breeding sites of this species to support higher densities. It appears that individual pairs of Vinous-throated Parrotbills can nest very close to one another, separated by no more than 3 m. No differences in breeding success were found, however, between solitary and loosely colonial nesting pairs of Vinous-throated Parrotbills during surveys in South Korea. In this species, the roles of the male and the female were found to be similar during the nest-building, incubation and nestling stages.

All parrotbills for which the relevant information is available construct deep cup-shaped nests, generally sited at relatively low levels. The material used in the construction consists of such items as dead reed blades and leaves of other marsh plants, grasses, strips of bamboo leaves, leaf skeletons, fine strips of bark, and in a few cases moss, and the structure is often reinforced with spider webs, which are plastered over the outside. The nest is generally lined with finer, softer material, typically fine grasses, fine roots, and shreds of dead leaves or bark, sometimes with hair and feathers added. Many parrotbill nests have a yellowish appearance overall, as a result of which they blend in extremely well with their surroundings and are often very difficult to locate.

The clutches of most parrotbills consist of two to four eggs, although the Ashy-throated Parrotbill normally lays three to five eggs, and occasionally six, and the Reed Parrotbill sometimes

lays five eggs. The exceptions to this general rule involve the two best-studied species. The Vinous-throated Parrotbill has a clutch size of three to seven eggs, five or six being the norm in South Korea and four or five in China and Taiwan. The most widespread member of the family, the Bearded Parrotbill, also lays the largest number of eggs. Its normal clutch is of 4–8 eggs, but up to eleven eggs have been recorded in a single nest.

Egg colour varies considerably among the species, and this further supports the subdivision of the family, in particular the

The **Reed Parrotbill** builds a beautiful cup-shaped nest supported in mid-air by three or more reed stems, a design similar to that of the Eurasian Reed-warbler (*Acrocephalus scirpaceus*).

The structure takes 6–7 days to construct from strips of dead reed sheaths, bound, rimmed and lined with filaments of dead reed stems, and wrapped with cobwebs for increased stability. The clutch, of 2–5 eggs, is incubated by both sexes for about 12 days. This species is the only member of the family with seasonal differences in plumage, the smart summer dress becoming generally duller in winter.

[*Paradoxornis heudei*  
*polivanovi*,  
Ussuriland, Russia.  
Photo: Yuri Shibnev]

The duties of nest-building, incubation of eggs and rearing of young are shared more or less equally by both sexes in the **Vinous-throated Parrotbill**. The nest itself is a shabby affair woven from coarse and fine grasses, leaves and fibres, and plastered with cobwebs. It is typically situated 40–90 cm above the ground among reeds, small bamboos, nettles (*Urtica*) or climbing plants, or in the fork of a bush; some have been found about 3 m up in small trees. In South Korean surveys, 141 nests were built in 28 different plant species, partly reflecting the broad overall habitat preferences. The species occurs in all kinds of marginal vegetation, such as secondary growth, plantations, scrub, hedges, bamboo groves, marshes and reedbeds.

[*Paradoxornis webbianus mantschuricus*, Ussuriland, Russia. Photo: Yuri Shibnev]

genus *Paradoxornis*, into several previously accepted genera (see Systematics). The eggs of *Panurus*, the Bearded Parrotbill, are creamy white, with fine dark brown markings. Those of *Conostoma*, the Great Parrotbill, have been described as dull white, sparsely blotched, streaked and smudged with pale yellowish-brown, and with pale inky-purple underspots and clouds; they have been said also to be white with sparse reddish speckles and/or blotches. The eggs of the Black-breasted, Spot-breasted and Reed Parrotbills, the "typical" *Paradoxornis* species (see Systematics), have a white or whitish ground colour with a tinge of green, brown or yellow, and with fairly varied brownish markings and paler brown to purplish undermarkings. No data are available for the Spectacled and Rusty-throated Parrotbills, but the remaining *Suthora*-type parrotbills lay plain bluish or white eggs. In contrast, the eggs of the *Psittiparus*-type species are more colourful: those of the Grey-headed Parrotbill have a whitish, greenish-white, grey, yellowish or reddish ground colour and those of the Greater Rufous-headed Parrotbill a whitish to dull cream-coloured or blue-grey ground, in both cases with complex buffish to brown or reddish markings and grey to purplish undermarkings. The Grey-headed Parrotbill's eggs are perhaps the most varied of those of any parrotbill. There is no information on the breeding of the third *Psittiparus*-type, the Black-crowned Parrotbill. Likewise, the eggs of the two *Heteromorpha* types, namely the Three-toed and Brown Parrotbills, and of *Neosuthora*, the Short-tailed Parrotbill, are currently undescribed.

Both Bearded and Vinous-throated Parrotbills often raise more than one brood in a year, and both have short nestling periods. Studies in South Korea revealed that some 23–27% of Vinous-throated Parrotbill pairs raise two broods during one season. A large proportion of pairs attempting a second brood were made up of the same two individuals as reared the first brood. In Taiwan, it was found that pair-members which succeeded in rearing more than 80% of the clutch to the fledging stage tended to remain together, and individuals which kept the same mate showed some signs of improved breeding success. Several double-brooded, monogamous bird species apparently exhibit high rates of mate-switching between nesting attempts within a single breeding season, but the rate of mate change among Vinous-throated Parrotbills is very low. It does, however, seem to be rare for a male to retain the same mate for more than one season. It was found that second nests were built close to the first nest if the latter had been successful, but far from it if it had failed, a strategy that is apparently employed as a means of reducing predation.

It is evidently common for single pairs of Bearded Parrotbills to begin laying in a new nest while still feeding a previous brood in a nest nearby. Under the correct circumstances, pairs can rear 10–20 young in a single season, one of the highest productivity rates of any European passerine. It has been postulated that early-reared young can themselves breed in August, after moulting. A captive juvenile in Europe apparently laid an egg on 21st July, after having completed an unusually early moult.

Of 33 nests of Bearded Parrotbills monitored during one study in Germany, 70% produced some fledged young, but only 51% of the total number of eggs laid produced fledglings. In another German study, it was found that 90% of 88 nests, and 63% of the eggs laid in 20 nests, produced fledged young. At 140 nests of Vinous-throated Parrotbills in Taiwan, the mean hatching success was 2.68 eggs per nest, corresponding to 64% of all eggs, and the mean fledging success was 1.9 young per nest, or 74% of hatchlings. In addition, pairs that laid larger clutches hatched significantly more eggs and fledged more young than did those laying smaller clutches. As one would expect, hatching and fledging success can vary significantly from one year to another. The proportion of Bearded Parrotbill eggs failing to hatch is also relatively high, with 11.4% recorded during one survey.

During the Taiwan studies, predation of Vinous-throated Parrotbill nests was found to be severe at both the egg stage and the nestling stage. Of 63 nests found before incubation had commenced, only 28, or 44.4%, survived to the hatching stage, and only 15 nests, just 23.8% of the total, produced any fledged young. On the other hand, nests that escaped predation had a high rate of hatching success, 87.8% of eggs laid, with an average of 3.9 eggs per nest.

Breeding success over two seasons of survey work in South Korea was about 43%. It has been found that clutches of six eggs have a higher hatching success rate than do those with four or five eggs. The Vinous-throated Parrotbill, which lays eggs of two different colour types, is a key host of the Common Cuckoo (*Cuculus canorus*) in South Korea. Results of studies there indicate that parrotbills laying white eggs, rather than blue ones, are favoured. It has been suggested that this egg-colour dimorphism evolved as a defence mechanism to combat perfect mimicry by parasites. It is thought that the egg mimicry on the part of the cuckoo has possibly evolved to match the most common egg colour type of hosts that exhibit egg-colour polymorphism. In South Korea, however, blue cuckoo eggs were found in both blue and white clutches of parrotbills, suggesting that the cuckoo did not discriminate between host egg colours when laying in nests of Vinous-throated Parrotbills. Egg colour is determined by the female parrotbill alone, and an individual will lay eggs of the same colour type throughout her life. Moreover, the egg colour type is apparently inherited by offspring.

Predation is the main cause of breeding failure of Vinous-throated Parrotbills, the primary natural culprits being the oriental tiger snake (*Rhabdophis tigrinus*) and the Eurasian Jay (*Garrulus glandarius*) in South Korea and snakes in Taiwan. In Taiwan, many nests were disturbed by humans, and some eggs and nestlings were taken. Other probable predators at the study site here included feral domestic cats (*Felis catus*), certain rodents (Rodentia), including the belly-banded squirrel (*Callosciurus erythraeus*), and an agamid lizard known as Swinhoe's japalura (*Japalura mitsukurii*). After heavy rain showers in Taiwan, adult parrotbills, with the plumage drenched, were seen to leave nests regardless of whether their mates had returned to replace them, and all of the instances of nest predation witnessed during studies occurred under such circumstances.

It appears that Vinous-throated Parrotbill parents encourage their offspring to leave the nest by calling to them, and that all the young leave more or less simultaneously. At two South Korean nests, it took 9–25 minutes for the six young to leave. Similarly, young Bearded Parrotbills are normally encouraged to leave the nest by their parents, which call and, as the chicks come out of the nest, hop away low down in the reeds, where they are followed by the youngsters. There have been reports that the male Vinous-throated Parrotbill, in captivity, often attacks and kills its offspring soon after the latter fledge. The extent to which such behaviour could be influenced by the unnatural circumstances of being held captive is not known.

Both sexes of the Vinous-throated Parrotbill become sexually mature after one year, and individuals of this species are known to have survived for at least seven years, although the maximum longevity is unknown. Pet stores report that this species dies more easily than do individuals of other wild-caught passerines. A ringed Golden Parrotbill lived for 11 years in the wild in Taiwan, and the longest-lived Bearded Parrotbill trapped to date was 6 years old.

During the seven-year study in Taiwan, the survival rate of Vinous-throated Parrotbills after their third year was found to be very low. Some did survive into their seventh year, but the majority died before reaching their fifth year. Juvenile survival to sexual maturity was high compared with mortality levels of older individuals. Predators on juvenile and adult Vinous-throated Parrotbills in Taiwan include the Brown Shrike (*Lanius cristatus*),

**The Bearded Parrotbill** is socially monogamous, although cases of bigamy have been reported. In typical pairs, both sexes build the nest, incubate the eggs, and feed the young. Clutches are highly variable in size from three to eleven eggs (usually 4–8). These are incubated for 10–14 days until they hatch, after which the nestlings are fed for 12–13 days, and sometimes up to 16 days.

This female is busy provisioning a brood of five very hungry chicks. They will leave the nest before they are able to fly, and will probably achieve full independence within two weeks of fledging. Each breeding season 2–4 broods are raised.

Photo: Alan Barnes/NHPA]

The **Brown-winged Parrotbill** is a poorly known species from the mountains of Myanmar and south China, where it occurs in marginal habitats, including scrub, grass and thickets, as well as open forest and at forest edges. It is locally fairly common, and its favoured habitats are likely to be increasing in extent, rather than decreasing. It is therefore not considered to be threatened. Its global range is highly circumscribed, however, falling mainly within the Yunnan Mountains Endemic Bird Area, and it therefore qualifies as a restricted-range species.

[*Paradoxornis brunneus brunneus*, Tengchong, Yunnan, China. Photo: John & Jemi Holmes]

feral domestic cats, and even the golden web spider (*Nephila maculata*), the large webs of which are so strong that parrotbills are unable to break free from them.

## Movements

Parrotbills are largely sedentary. The only long-distance migrant in the group is the Bearded Parrotbill, which is well known for its periodic eruptive movements. These are thought to be an adaptation for relieving population pressure in breeding areas, and for colonizing new sites. Eruptions take place in the period September–November, after the breeding season has been completed, and involve mainly juveniles. Flocks rise steeply to 50–60 m or more, and small groups of individuals then break away and disperse out of sight. The direction taken by the parrotbills, which typically travel in pairs and groups, is dependent on the geographical occurrence of reedbeds. Some establish new colonies in the place where they spend the winter months, while others return to the site of origin in the following spring, in March–May. In Europe, a rapid increase in the breeding population of the Bearded Parrotbill in the Dutch polders during the 1950s and 1960s resulted in major eruptions during the 1960s and 1970s, scattering potential colony pioneers widely across north-western Europe. Of 7450 individuals ringed in Suffolk, in east England, during 1959–1973, a total of 53 was recovered in autumn and winter in Suffolk, whereas 113 were found in other English counties during those seasons.

It has been suggested that high-flying behaviour in winter and spring by Vinous-throated Parrotbills may similarly be linked with eruptive movements by pairs of this species. The young of this parrotbill undertake post-fledging dispersal soon after they become independent, at which time they leave the natal site with others of the species and move to the non-breeding range. Some cold-weather movements are recorded for Vinous-throated Parrotbills in north-east China and east Russia, between September and March/April, and there is also a record of a vagrant from the west coast of Japan.

Some parrotbill species make minor altitudinal movements, descending to lower, warmer, snow-free levels during hard weather. Even some of the small members of the family, however, are very hardy, and the extent of these winter movements has probably been exaggerated to some extent by certain authors.

## Relationship with Man

Parrotbills have no obvious relationship with human beings, apart from through the cagebird trade. Otherwise, the only interactions between parrotbills and man appear to be indirect ones, one such example being the adverse impact of human activities on parrotbill habitats (see Status and Conservation). Parrotbills do, however, hold a great appeal for birdwatchers, and many species are much sought-after subjects for observation.

Many species of parrotbill have been recorded as being kept in captivity, and there are regular shipments of wild-caught individuals from China to Europe and elsewhere. The most popular species appear to be the Vinous-throated and Grey-headed Parrotbills, reflecting their extensive Chinese ranges. Shipments of the former from the western extremities of its range have also included Ashy-throated Parrotbills, and these two species have recently established feral populations in Italy, originating from

The **Black-breasted Parrotbill** occurred in the tall grasslands of north-east India and Bangladesh. It is now restricted to Assam, having disappeared elsewhere due to the destruction of grassland habitats by drainage and conversion. Remaining grassland fragments are heavily overgrazed, and intensively used by local people who harvest them up to three times a year for fodder and thatching. The species is classified as Vulnerable, and its survival depends on protected areas in India's Brahmaputra valley.

[*Paradoxornis flavirostris*, Dibru-Saikhowa National Park, Assam, India. Photo: Edward Vercruysee]

The **Grey-hooded Parrotbill** is a restricted-range species inhabiting open forest and scrub on exposed peaks and ridges in the Central Sichuan Mountains Endemic Bird Area. It is known from very few localities, and it may be under threat from habitat loss. However, it can survive at fairly high population density, and it is not clear whether its mountaintop environment is under much pressure. Moreover, its range is difficult to access and the species may be more widespread than current records suggest. It is thought to have a declining and severely fragmented population, and is classified as *Vulnerable*. Further surveys are necessary.

unwanted birds that were deliberately released into the wild. Fulvous Parrotbills are also kept in captivity, and they have been bred in the United Kingdom, at least.

In south-east China, seven members of this family were found in Liuhua market, in Guangzhou, during 2000–2003 alone. These are the Bearded, Great, Grey-headed, Spot-breasted, Vinous-throated, Golden and Short-tailed Parrotbills. Other species that have been kept in captivity include the Greater Rufous-headed and Reed Parrotbills, and it is likely that small numbers of the remaining species, too, have been held as captives.

Although there is no evidence that the illegal cagebird trade is having an impact on wild parrotbill populations, it is, in any case, a cruel and unnecessary business and one that should be more effectively prohibited.

### Status and Conservation

Globally, most parrotbill species are fairly common and widespread in relatively little-threatened habitats. Three species, however, are considered globally threatened. These are the Black-breasted, Grey-hooded and Rusty-throated Parrotbills, all of which are included in the conservation category of *Vulnerable*.

The Black-breasted Parrotbill is restricted to the Assam Plains Endemic Bird Area, in north-east India, and its current population size is unknown, but believed to be declining. It is already extinct in neighbouring Bangladesh. The primary threat to this species is the loss and degradation of its grassland habitat to agriculture and forestry plantations, dam and irrigation schemes, overgrazing by domestic livestock, and the intensive harvesting of the vegetation by local communities. This last activity is often associated with the use of burning.

Grey-hooded and Rusty-throated Parrotbills are primarily inhabitants of areas of bamboo in remote open forests of western China, and it is basically because of their small population sizes that they are considered to be *Vulnerable*. There is, however, no clear evidence that the population of either species has declined. The Grey-hooded Parrotbill has been recorded from only nine sites, and the Rusty-throated from four. Although status information is rather lacking, it seems that Grey-hooded Parrotbills can exist at fairly high densities in suitable habitat, but the small number of localities and the species' highly localized distribution suggest that it could have a small total popula-

tion. Virtually no information is available on the current population of the Rusty-throated Parrotbill, which is the least-known of all parrotbills. This species has been observed recently only at Jiuzhaigou Nature Reserve, in north Sichuan, and even there it has not been seen with any sort of regularity since a mass flowering and subsequent die-off of bamboo in the late 1980s. The main threat to these two species is likely to be direct loss and fragmentation of habitat.

A further species, the Reed Parrotbill, is placed in the conservation category of *Near-threatened*. Although originally believed to have a very small and fragmented population, this species is now known to inhabit an extensive range in east and north-east China, east Mongolia, and the Lake Khanka region of south-east Russia. As with the Black-breasted Parrotbill, the main threats to its survival are associated with the mismanagement and clearance of its grassland, reedbed, habitat. In the case of this species, the over-harvesting of reeds, instead of a wildlife-sympathetic rotational method of reed-gathering, has been cited as a primary cause for concern. Others mentioned are the large-scale destruction of reedbeds for paper pulp and the reclamation of tidal lands for cultivation.

Notwithstanding the above, the most marked population fluctuations recorded for any parrotbill are those of the most widely distributed member of the family, the Bearded Parrotbill. This species' population in the East Anglia region of England was thought to number as few as 2–4 pairs in 1948, but by 1974 it had risen to 590 pairs; currently, the Norfolk population is in decline. In the Netherlands, 30,000–55,000 pairs of Bearded Parrotbills were estimated in 1965 and 1973, but only 700–1400 in 1983, this huge reduction thought to have been caused at least in part by loss of habitat. In 1989–1991, the Dutch population was estimated to number 1300–2000 pairs.

## PLATE 25

## Family PARADOXORNITHIDAE (PARROTBILLS) SPECIES ACCOUNTS

### Genus *PANURUS* Koch, 1816

#### 1. Bearded Parrotbill

##### *Panurus biarmicus*

**French:** Panure à moustaches **German:** Bartmeise **Spanish:** Bigotudo  
**Other common names:** Bearded Tit/Tit-babbler, (Bearded) Reedling, Whiskered Tit

**Taxonomy** [*Panurus*] *biarmicus* Linnaeus, 1758, Europe = Holstein, north Germany. Range of plumage variation considered by some authors to be perhaps at least partly clinal, such that the species may be better treated as monotypic. Unclear whether populations of E Baltic (between Finland and Poland) belong to nominate race or *russicus*, which presumably intergrade in Poland and Slovakia and perhaps elsewhere in E Europe. Birds in E Turkey, Georgia and Armenia presumably like those from Azerbaijan, presently included in nominate; racial identity of those breeding in Syria uncertain, tentatively included in *kossigi*. Three subspecies currently recognized.

##### **Subspecies and Distribution**

*P. b. biarmicus* (Linnaeus, 1758) – breeds locally from England, France and S & E Spain E to S Norway, Denmark, S Sweden, S Finland, SW Russia, Balkans, W & S Turkey and Azerbaijan, non-breeding also S to Cyprus.

*P. b. russicus* (C. L. Brehm, 1831) – breeds S Lithuania, Poland and Belarus S to E Austria, NE Croatia, NE Bosnia-Herzegovina, N Serbia & Montenegro, N & E Bulgaria and C Turkey, E to S Russia (S from L Chany, SW Siberia and Tarbagatay, and S of L Baikal), Kazakhstan, Mongolia and N & NE China (Xinjiang, N Qinghai, W & NE Nei Mongol, Ningxia, NE Heilongjiang); non-breeding also Israel, N Iran (mainly Caspian coast), E China (N Hebei and SC Liaoning) and NE Afghanistan (may breed).

*P. b. kossigi* Kumerloewe, 1958 – S Turkey (area around Amik Gölü, at least) and NW Syria.

**Descriptive notes** 14–5, 17 cm; 11–20.8 g. The only sexually dimorphic parrotbill. Male nominate race has medium blue-grey or ash-grey forehead to nape, and sides of head and neck (from below eye backwards), often hint of darker lateral crownstripe, with black lores, neck and long moustachial and malar areas usually narrowly whitish bordered above lores and at rear; upperparts pale rufous-chestnut, outer scapulars buffier to buffish-white, inner scapulars with slight vinous-pink tinge. Flight-feathers and primary coverts dark brownish-grey to greyish-black, primaries P6–P9 and their coverts with narrow white outer fringes (forming distinct white panel on closed wing), P1–P5, P10, secondaries and other primary

coverts with rufous-chestnut outer edges (but white towards base of P1–P5), tips of secondaries and inner primaries narrowly fringed pink-cinnamon or cream-buff (inner webs more broadly so); outer two tertials black on shaft and outer web, white or cream-pink on inner web, innermost tertial largely white, tertial fringes pale rufous-chestnut to pink-cream; greater and median upperwing-coverts black with rufous-chestnut fringes (broadest on outer greater), lesser coverts mottled pale grey, buff and creamy white, alula black with broad white fringe along outer web; uppertail pale rufous-chestnut or cinnamon-chestnut with slight grey wash, tips of feathers T3 and T4 with slight pale ash-grey wash, tips and outer webs of T5 and T6 extensively pale ash-grey (whiter than T3 and T4) and with variable amount of black at base, some blackish often present also on outer fringes and tips of T3–T6 and occasionally on tips of T1 and T2; throat white to creamy, breast centre either white with faint grey wash or tinged vinous-pink, belly centre creamy buff, flanks as mantle and scapulars or slightly paler, undertail-coverts black; in worn plumage (spring and early summer), head duller grey (less bluish), mantle, scapulars and central rectrix paler (buffier), more cream and white of outer scapulars visible, uppertail-coverts more extensively vinous-pink, throat and centre of abdomen sometimes more extensively white to creamy (but belly side often less so), and tail tips heavily abraded; iris yellow or light orange-yellow, rarely dark brown, greyish-yellow or yellow-brown, generally brighter yellow-orange in spring; bill orange-yellow, orange-brown or bright orange; legs black, occasionally with brown or yellow-brown tinge, exceptionally bright yellow. Female has drab brown forehead to nape, often some black spots/mottling on centre, side or rear of crown (sometimes in pattern of two rough lateral crownstrips which coalesce on nape), occasionally completely streaked black (except for forehead and supercilium); upperparts similar to those of male but a little duller, usually some black streaks on lower mantle, inner scapulars and back, sometimes heavily streaked, the streaks coalescing to form black patch on lower mantle; lores mottled dull grey and pale buff, cheek and head side behind eye pale grey with variable vinous-pink tinge, ear-coverts and neck side tinged warm buff to variable extent, occasionally some black spots or shaft streaks on lower cheek; wings as male, but white fringes of outer primary coverts less pronounced and tinged buff, fringes along outer webs and tips of secondaries, tertials, inner primaries and greater upperwing-coverts slightly paler; tail as that of male, but generally slightly paler-tinged; underside as male, but vinous-pink tinge usually paler and less extensive, flanks paler (less rufous), abdomen centre often more extensively cream, undertail-coverts warm buff (not black); in worn plumage, slightly paler and greyer above, with more pronounced black markings (if present), uppertail-coverts extensively pale vinous-pink, largely dirty white below, with restricted pale vinous-pink on head side and upper flanks, pale buffy-brown lower flanks and undertail-coverts; bare parts as male, but iris yellow to reddish-amber in spring, bill yellow-brown, greenish-horn or grey-brown with yellow or yellow-orange cutting edges and lower mandible. Juvenile resembles female, but much buffier (less chestnut-tinged) above, on flanks and on central pair of tail feathers, has largely black lower mantle to back and rectrices T2–T6, blacker wings with pale fringes buffier and more restricted (those of P6–P9 creamy white), and duller underparts lacking vinous-pink tinge, young male with black lores, green-grey to yellow-green iris (week 3–6) becoming light yellow to orange around time of juvenile moult, bill yellow to orange, legs initially paler than adult, young female with lores dull grey with some buff mottling, bill horn-brown, grey-brown or blackish. Races vary mainly in depth of ground colour of head and body (both sexes) and in amount of black streaking on head and upperparts of female: *russicus* is paler than nominate, male crown pale blue-grey or pale ash-grey, mantle, scapulars and fringes of greater upperwing-coverts and secondaries more buffy rufous, mantle and scapulars sometimes tinged pink-grey, uppertail-coverts pale vinous-pink, female crown and upperparts only faintly streaked or unstreaked, underparts largely creamy white, buff tinge only on lower flanks and undertail-coverts, vinous-pink pale and restricted, juvenile has paler yellowish-buff base colour; *kossiwigi* is similar to nominate, but has darker and more rufous-brown upperparts and flanks, male rather dark grey on head and intense vinous-pink on breast and belly side, with uppertail-coverts deep vinous-pink, female with very little black streaking on mantle and scapulars. Voice. Male's song "tschindschik-tschrää" or "ts'chin-dschik-tschrää" lasting 2 seconds or slightly longer, with "tschrää" note harsher and second note shorter and softer than first, usually preceded by 3–5 introductory "tschin" notes (can be omitted if song quickly repeated); has also been described as "tschin-tik (tschri)-tschiuu", final note more drawn out and melodious, and as loud "chveen-chveen". Typical call a distinctive ringing "ping ping" or "tschin tschin"; plaintive "tuu" or "tjuu" notes from flocks often mixed with typical call; very soft "djipp" or "djupp" contact calls; soft "pitt pitt" in vicinity of nest, also "tze-tze-tze" or "tje-tje-tje" by parents contacting fledged young; when excited, utters harder "tjick" or "tschick", "tjipp" or "ticio", becoming sharper and more rapidly repeated as excitement increases; in alarm, scolding "t-tzääahh", "schra", "dschraahh" and "djschirr", as well as guttural "p/whut", plaintive "ee-ar, ee-ar" and churring "chirr-irr-irr-irr".

**Habitat.** Extensive reedbeds (*Phragmites*) and associated dense non-woody vegetation in and beside fresh and brackish water, or immediately adjoining marshes and swamps; tussocky edges of reedbeds; stands of reeds and bulrushes (*Typha*) in marshes and along shores of lakes and rivers. Vagrants have been recorded in wild sugar cane (*Saccharum*) and tamarisk (*Tamarix*) scrub. From sea-level to medium elevations; to at least 3050 m in China (Qinghai).

**Food and Feeding.** Feeds mainly on invertebrates and their larvae in summer breeding season; vegetable matter in late autumn and winter. Summer diet includes, among others, springtails (Collembola), mayflies (of family Polymitarcidae), damselflies (Zygoptera), stoneflies (Plecoptera), bugs (Hemiptera, including Veliidae, Delphacidae, Aphididae), moths (of family Noctuidae), caddis flies (Trichoptera), craneflies (Tipulidae), mosquitos (Culicidae), non-biting midges (Chironomidae), gall midges (Cecidomyiidae), soldierflies (Stratiomyidae), Hymenoptera, beetles (of families Halipidae, Dytiscidae, Hydrophilidae, Coccinellidae, Chrysomelidae, Curculionidae), spiders (Araneae) and slugs/snails (Gastropoda). Tends to catch relatively slow-moving insects, non-biting midges gathered from water's edge featuring frequently in diet. During breeding season, may be able to catch large numbers of larvae or pupae of various wainscot moths (Hadeninae), pale cream caterpillars of which feed within reed stems but emerge to pupate; these caterpillars can sometimes be identified at long distances as primary foods brought to a nest. In late autumn and winter, diet consists mainly of seeds (also plant fibres), including those of bulrushes, sedges (Cyperaceae), reeds and various other grasses (Gramineae) and rushes (Juncaceae); those of common reed (*Phragmites australis*) the most widely sought-after. Wandering flocks sometimes found away from reeds, and have been noted as taking seeds of knotgrasses (Polygonaceae), goosefoots (Chenopodiaceae), common nettle (*Urtica dioica*), great willowherb (*Epilobium hirsutum*), willows (*Salix*), mints (*Mentha*), and sometimes sea-buckthorn (*Hippophae rhamnoides*). Diet of dependent young lacks plant material, but becomes more varied soon after independence. Forages in pairs and family parties, and in post-breeding flocks of up to 40–50 or even 200 or so. Feeding areas are typically near standing water, well separated from nesting areas; often feeds at base of reeds, forages also on muddy ground and at margins of open water. Regularly climbs to top of reed

stems and flies short distances above reeds. Searches broken and cracked stems, and makes rapid darting movements to catch passing insects; sometimes hangs upside-down when feeding, and sometimes uses its bill or foot to pull a seedhead closer. Draws parts of reed-heads through its bill while nibbling to extract seeds. Hops and runs quickly on the ground, scratching earth and turning over reed leaves in search of food. In cold weather, feeds on fallen seeds and even probes snow.

**Breeding.** Season late Mar to early Sept in W Palearctic; regularly 2–4 broods. Monogamous, but bigyny also reported. Nest built by both sexes, a deep cup-shaped structure of dead reed blades and other marsh-plant leaves, lined with flowering reed-heads, usually also feathers and occasionally mammal hair (lining material often added through egg-laying and even incubation periods), nearly always roofed by sheltering vegetation, outer diameter 8–15 cm, height 6–23 cm, inner diameter 6–6.8 cm, cup depth 5–5.8 cm; placed 5–72 cm up (those above water typically higher) among close-growing and typically more or less vertical stems of reeds, sedges and other marsh vegetation, exceptionally built into rim of heron (Ardeidae) nest; artificial nests accepted. Clutch 3–11 eggs, usually 4–8, smooth and glossy, white to creamy, lightly and finely streaked and speckled dark brown, dimensions 14.5–19.7 × 12.4–15.1 mm; incubation by both sexes, period 10–14 days; chicks cared for by both parents, nestling period usually 12–13 days, sometimes up to 16 days, young may leave nest at 10 days if disturbed, and apparently typically leave before able to fly; rarely dependent for more than two weeks after having left nest.

**Movements.** European populations mainly fairly sedentary, but subject to eruptive post-breeding and wintering movements, sometimes resulting in establishment of new colonies; other erupting individuals return to source site to breed in following spring. Birds which leave breeding grounds for winter depart Sept–Nov (mainly Oct) and return Mar–May. Rapid increase in breeding population of the Dutch polders during 1950s and 1960s resulted in major irruptions during 1960s and 1970s across NW Europe. Vagrants of nominate race recorded in Republic of Ireland (bred 1976–1985, at least) and N Africa (Morocco, Algeria), and of race *russicus* in Kuwait, Pakistan, Korea and Japan; erratic winter visitors to Syria not identified subspecifically.

**Status and Conservation.** Not globally threatened. Generally fairly common to common in places where established as a breeding species. Breeding numbers, however, may show regular annual fluctuations, and have probably always risen and fallen locally, to a considerable extent. Range currently expanding in much of Europe; has increased in some areas after an earlier decline, as well as colonizing new areas. Population is likely to increase further where winter weather conditions are becoming milder. In other regions (e.g. Turkey), breeding population thought to be decreasing, primarily as a result of drainage of marshland habitat. In S Turkey, race *kossiwigi* has never been collected outside area around Amik Göldü, where it was present until at least 1956 but was apparently extinct by 1962.

## Genus CONOSTOMA Hodgson, 1841

### 2. Great Parrotbill

#### *Conostoma aemodium*

French: Grande Panure German: Riesenpapageimeise Spanish: Picoloro Grande

**Taxonomy.** *Conostoma* [sic] *Emodium* [sic] Hodgson, 1841, northern Nepal.

Original description included two different spellings of genus name (*Conostoma*, *Conostama*) and three of species name (*aemodium*, *aemodius*, *omodius*); both elements of current name determined by ICZN Principle of First Reviser. Genus name has been claimed to be preoccupied by the name of an insect genus, with replacement name *Emendrodzovoma* proposed; however, several significant uncertainties surround this claim, and so long-established and almost universally used current name should be retained until satisfactorily proven otherwise. Monotypic.

**Distribution.** Himalayas from N India (E Uttaranchal Pradesh) E to E Bhutan, and locally in adjacent areas of S Xizang (S China); also, disjunctly (on basis of present knowledge), in C China (SW Shaanxi and S Gansu S to Sichuan and NW Yunnan) and E part of N Myanmar.

**Descriptive notes.** 27.5–28.5 cm; c. 88–110 g. Adult is much larger than other parrotbills, and relatively long-billed. Forehead is greyish-white, fading onto crown; otherwise, mousy greyish-brown with faint warm tinge above, slightly greyer on crown, rump and uppertail-coverts; lores and orbital area blackish-brown, head side similar in colour to upperparts; flight-feathers dark grey with buffish-cream inner fringes, primaries P5–P10 have pale ash-grey outer fringe towards tips (after emargination), becoming greyer towards base, and tinged with colour of upperparts close to base, inner primaries mid-grey on outer webs and washed

with colour of upperparts; strong rufescent wash over outer webs of secondaries and tertials, extending just to innermost primaries; tail medium grey, becoming similar in colour to upperparts towards centres of feathers; mostly ashy grey below, with vague paler and darker streaks on throat to ear-coverts, flanks with wash of similar colour to that of upperparts (or a shade greyer); iris pale yellow or pale orange-yellow to ochre-brown; bill orange-yellow, yellow at tip of upper mandible,

Has sometimes been placed in a genus *Psittiparus*, along with *P. ruficeps*. Until recently considered conspecific with *P. margaritae*, but the two differ somewhat in morphology, plumage and voice. Birds in parts of S China of uncertain racial identity, those in W & NW Yunnan presumed to belong with *translivialis* and those in S Yunnan and SW Guangxi with *laotianus*. Former race considered of doubtful validity by some authors, and may be better merged with nominate. Likewise, *laotianus* differs only slightly from *fokienensis* and perhaps better synonymized with it. Six subspecies currently recognized.

## 7. Black-breasted Parrotbill

### *Paradoxornis flavirostris*

**French:** Paradoxornis de Gould

**German:** Schwarzkehl-Papagei

**Spanish:** Pícoloro Pechinegro

**Other common names:** Gould's Parrotbill

**Taxonomy.** *Paradoxornis flavirostris* Gould, 1836, probably Nepal (north West Bengal, India, later considered more likely).

Formerly treated as conspecific with *P. guttaticollis* by some authors, but is morphometrically quite distinct and differs in vocalizations and, especially, in habitat requirements; ranges of the two overlap (or formerly overlapped) in parts of NE India, but they are ecologically separated. Monotypic.

**Distribution.** R Brahmaputra floodplains in NE West Bengal, NE Assam and immediately adjacent areas of Arunachal Pradesh, in NE India. Contrary to some published reports, not present on Mt Victoria (W Myanmar).

**Descriptive notes.** 19.5–21 cm. Has forehead to nape chestnut-brown, lores and ear-coverts blackish with variable white mottling below eye, neck side (area behind ear-coverts) chestnut; upperparts rufescent brown; flight-feathers and tertials dark brown with creamy-buff inner fringes, dark rufous outer fringes, outer edges of most primaries paler and duller towards tips; upperwing-coverts dark brown, outer fringes similar in colour to upperparts; uppertail dark brown, outer fringes brighter; chin to upper breast mostly black, variable white mottling on throat; underparts deep rufescent-buff; iris deep red or red-brown to olivaceous brown; bill wax-yellow to bright or deep yellow; legs slate-coloured to plumbeous grey. Distinguished from similar *P. guttaticollis* by darker and more chestnut forehead to nape, blacker lores, more chestnut-tinged rear neck side, mostly black chin to upper breast, and much darker and warmer underparts. Sexes alike.

**Behaviour.** Juvenile is richer rufous above, with duller bill. **Voice.** Song, given often from any exposed perch (e.g. tall reed stem), of 4–7 clear, quite high notes, e.g. "woi-woi-woi-woi-woi" or "wui-wui-wui-wui-wui" or "whii-whii-whii-whii", and huskier "jhor-jhor-jhor-jhor-jhor" or "jhui-jhui-jhui-jhui-jhui"; these vocalizations sometimes accompanied by antiphonal worried-sounding "er-er-er-er-er-er" or "uu-uu-uu-uu-uu", and slow "whittittittit" (possibly from female). Other calls include clear, rather high "wu, wi, wi" and "wu, wi, wi, wii" ("wu" notes lower) mixed with low, slightly nasal "uh-uh-uh-uh-uh".

**Habitat.** Tall mixed grassland, including ekra (*Erianthus ravanee*) and wild sugar cane (*Saccharum*), along riverbanks and seasonally inundated riverbeds; possibly also frequents bamboo and wild cardamom in some areas. Restricted to plains level; formerly occurred as high as 915 m.

**Food and Feeding.** Diet consists of a mixture of small invertebrates and seeds. Various insects, including earwigs (Dermaptera) and beetles (Coleoptera), and their larvae (particularly during breeding season); also berries. Forages in small parties of up to twelve individuals, often 7–8, during non-breeding season. Fairly shy. Often keeps low down, close to ground, when foraging, but periodically ascends to tops of reed or grass stems (particularly when calling). Obtains food from cracks and crevices in reeds and various grasses; makes loud noises when nibbling at flowers of these plants.

**Breeding.** Mar–Jul. Nest a very neat, compact deep (rarely shallow) cup constructed from fine strips/shreds of bark or coarse grasses and bamboo leaves (occasional dead leaves), bound with cobwebs (rarely, fine elastic twigs), lined with fine pieces of grass, bark and occasionally hair (nest is of a bright, clear yellowish colour, blending perfectly with surroundings), external diameter 8.4–10.2 cm, height 6.4–7.6 cm, internal diameter 6.3 cm, depth 5.1 cm; placed 1–3 m above ground, usually fixed to three or four reed stems or in cluster of twigs jutting out from a bamboo node, exceptionally in a sapling. Clutch 2–4 eggs, smooth, sometimes faintly glossed, usually very pale greenish-white, sometimes tinged brownish or yellowish, or almost white, scantily marked with minute freckles to large blotches of pale amber or olive-brown over paler undermarkings of same colour and a few short twisted lines of dark amber (one clutch described as showing a few very faint pinkish/purplish-brown specks at larger end), average dimensions 21.9 × 16.2 mm. No other information.

**Movements.** Sedentary.

**Status and Conservation.** VULNERABLE. Restricted-range species: present in Assam Plains EBA. Rare to uncommon, and local. Formerly more widespread, and once occurred also from NE Bangladesh E to plains of Cachar, in S Assam. Despite some published statements, is not present on Mt Victoria, in W Myanmar. Population size unknown but, in view of paucity of recent records and the widespread reduction in area of its habitat, it is believed to be declining. Historically in Indian Subcontinent, was regarded as fairly common in Assam (including Cachar) to rare in the Bhutan duars. The few recent sightings have come from Assam, where extensive habitat remains for the species in Dibru-Saikhowa National Park and, to lesser extent, Kaziranga National Park; recent records also from Jaldapara Wildlife Sanctuary (West Bengal), and D'Ering Memorial Wildlife Sanctuary (Arunachal Pradesh). In Bangladesh, was formerly scarce to uncommon along R Kushiara, although earlier authors suggested that it was rather common in Sylhet and regularly encountered when travelling by boat through this district; no extensive patch of tall grassland remains in Bangladesh, and surviving fragments generally heavily used and harvested up to three times a year for fodder, thatching and building materials; reedbeds of NE Bangladesh were leased out for paper production in 20th century, and reported to have been entirely destroyed. Primary threat is loss and degradation of habitat. Huge areas of grassland throughout this species' former range have been converted to agriculture and forestry plantations, others have been modified as flooding regimes have been changed by dam and irrigation schemes, and many remaining grasslands are overgrazed by domestic livestock and intensively harvested by local communities (often associated with burning). In many areas, grasslands of conservation value are virtually confined to protected areas, but here, too, they continue to suffer degradation. Grasslands are generally poorly represented in protected-area systems, although in Assam there is a preponderance of grassland in protected areas and a shortage of forest. Even in the Brahmaputra floodplain in Assam, however, the state and local distribution of this habitat can be altered by annual flooding.

## 8. Spot-breasted Parrotbill

### *Paradoxornis guttaticollis*

**French:** Paradoxornis fléché **German:** Brustflecken-Papagei **Spanish:** Pícoloro Pechipinto

**Other common names:** White-throated/Spotted-breasted/Rufous-headed Parrotbill

**Taxonomy.** *Paradoxornis guttaticollis* David, 1871, western Sichuan, China.

Formerly treated as conspecific with *P. flavirostris* by some authors, but is morphometrically quite distinct and differs in vocalizations and, especially, in habitat requirements; ranges of the two overlap (or formerly overlapped) in parts of NE India, but they are ecologically separated. Proposed race *gongshanensis* (from W Yunnan, in S China) considered of very dubious validity. Treated as monotypic.

**Distribution.** NE India (Himalayas of extreme E Arunachal and hills S of R Brahmaputra), W, N, E & S (E part) Myanmar; N part of NW Thailand, N Laos, N Vietnam (W & E Tonkin) and C, S & SE China (S Gansu and S Shaanxi S to WC Sichuan and Yunnan, E through Guizhou, N Guangxi and N Guangdong to N Fujian).

**Descriptive notes.** 18–22 cm; male 28–40 g, female 26.5–35 g. Has rufous crown and nape, very slightly buffier forehead, and rufescent-brown upperparts; lores mostly black with buffish-white to pale buff admixed, prominent large blackish ear-covert patch (including lower moustachial/malar area), buff neck side behind ear-coverts; upperwing dark brown, darker on inner webs, flight-feathers and tertials with creamy-buff inner fringe, dark rufous outer fringes (warmer than upperparts, but not so bright as crown), outer edges of primaries P2–P8 paler and duller towards tips (after emargination); upperwing-coverts and

uppertail dark brown, with outer fringe brighter (similar in colour to upperparts); cheek to throat side and area just behind eye pale buff to buffish-white with greyish streaks, mottling or speckles; remainder of underside buff to pale buff, with mostly blackish chin, and sooty inverted chevrons or streaky spots on throat and upper breast; iris brown to red-brown or chestnut; large, short and very deep-based bill bright yellow, orange-yellow or wax-yellow, tip sometimes browner; legs slaty, bluish-grey or greenish-plumbeous. Sexes alike. Juvenile is similar to adult, but has paler crown, more rufescent upperparts and wing and tail fringing, and more buff-tinged underparts. **Voice.** Song, from exposed perch, e.g. top of tall grass stem, a loud staccato series of usually 3–7 notes, repeated every 1.5–1.5 seconds, "whit-whit-whit-whit..." and jollier "wui-wui-wui-wui", "whi-whi-whi-whi", "dri-dri-dri-dri-dri" and "tui-tui-tui-tui-tui", or shorter strident "du-du-du", when excited, may give longer "ju-ju-ju-ju-witwitwitwit witwitwitwitwitwit" or "ju-ju-ju-ju-witwitwitwitwitwit...", starting with hurried rising notes and culminating in thin, higher-pitched, quite metallic ones; also gives introductory series alone, and makes coarse sounds (harsher than similar territorial calls), as "ee-cho-cho-cho-cho", "chow-cho-cho-cho-cho-cho", "jieu-jieu-jieu-jieu" and "ju-ju-ju-ju-dui-dui" and so on. Contact calls include low "ruk-ruk", "ruk-uk-uk", "rut-rut-rut-rut", "chi-cho-cho" and sibilant "chu-chu" and "chut-chut-chut".

**Habitat.** Grass and scrub, abandoned cultivation, and bamboo. Occurs at 900–2100 m in India, 1050–2135 m in SE Asia, and 350–3250 m, possibly to 3355 m, in China.

**Food and Feeding.** Diet insects and their larvae, seeds and berries; seeds include those of cultivated millet (*Panicum*). Forages in small parties; occasionally joins bird waves, which may contain such timioid species as Rufous-necked Laughingthrush (*Dryonastes ruficollis*) and harwings (*Actinodura*). Breaks open grass stems in search of food.

**Breeding.** Apr–Jul. Thought to be strongly territorial during breeding season, at least; sings frequently. Nest a very compact and deep cup-shaped structure, made from soft yellowish and other grasses, and bamboo leaves, usually plastered with cobwebs, and lined with finer yellowish (sometimes darker) strips of grass, internal diameter c. 5.1 cm and depth c. 6.3 cm; situated 0.9–1 m, sometimes to 3–7 m, above ground in reeds, bamboo clump, shrub or among stout weeds. Clutch 2–4 eggs, smooth and slightly glossy, variably patterned, one variety described as pale green-grey with numerous but faint blotches and smudges of sepia and brown and underlying spots of lavender and a few dark brown scrawls (said to be indistinguishable from those of *P. flavirostris*), in Myanmar and China said to be white or whitish with sparse speckles or spots and often hair-lines of pinkish-brown, buffy red and often various shades of lilac and grey, dimensions 22.1–23.5 × 15.8–16.5 mm (one from China 22.5 × 17 mm). No other information.

**Movements.** Sedentary; possibly performs some very local and minor altitudinal movements in China.

**Status and Conservation.** Not globally threatened. Very widespread, and generally fairly common in favourable habitat.

## 9. Spectacled Parrotbill

*Paradoxornis conspicillatus*

**French:** Paradoxornis à lunettes **German:** Brillenpapagei **Spanish:** Pícoloro de Anteojos  
**Other common names:** Spectacled Crowtit

**Taxonomy.** [Suthora] *conspicillata* David, 1871, easternmost Kokonor [= Qinghai Hu], China. Sometimes placed together with *P. webbianus*, *P. brunneus*, *P. alphonisianus*, *P. zappeyi*, *P. przewalskii*, *P. fulvifrons*, *P. nipalensis*, *P. verreauxi* and *P. atrosuperciliaris* in a separate genus, *Suthora*. Race *rocki* not very distinct (slightly thicker bill was greatly exaggerated in the text figure in type description), and supposedly paler plumage and lighter brown head not discernible on museum specimens examined; species may be better treated as monotypic. Two subspecies tentatively recognized.

**Subspecies and Distribution.**

*P. c. conspicillatus* (David, 1871) – C China from E Qinghai E to S Gansu, NC & NE Sichuan and S Shaanxi, China.

*P. c. rocki* (Bangs & J. L. Peters, 1928) – W Hubei, in EC China.

**Descriptive notes.** 14–15 cm; 8–9 g. A relatively small and long-tailed parrotbill, recalling *P. webbianus*. Has forehead to nape dull chestnut-brown, merging into colour of upperparts on centre of upper mantle; lores to cheek sooty-coloured, offsetting prominent white eyering; upperparts greyish olive-brown with buff tinge, becoming slightly buffier on uppertail-coverts; flight-feathers and tertials dark greyish-tinged brown with creamy-buff inner fringe, upperwing-coverts and outer fringes of tertials and flight-feathers similar in colour to upperparts, outer fringes becoming paler and more ashy-coloured towards tips (after emargination) of all

primaries except P9 and P10 (sometimes along most of length of outer fringe and extending to outer secondaries); tips of all remiges also paler and more ashy-coloured; tail drab greyish-brown; ear-coverts and neck side vinous-brown, throat and upper breast pinkish-grey to pinkish-brown (paler pinkish-cream centre) with quite broad sooty-brown streaks, remainder of underparts similar to upperparts but paler and a little buffier; iris brown; bill yellow to yellowish-white; legs grey-brown. Sexes alike. Juvenile is darker and more uniform above than adult, with slightly more rufescent upperparts, uppertail and wings, has slightly less pronounced throat and breast streaking, slightly darker and warmer lower underparts, and considerably narrower bill. Race *rocki* differs from nominate only in slightly thicker bill and apparently very slightly larger overall size. Voice. Song a very thin, high, piercing, penetrating series of 4–5 notes, “tsiu-tsiu-tsiu-tsiu”, “ssiu-tsiu-tsiu-tsiu” or “hsiu-tsiu-tsiu-tsiu”, slightly rising, repeated after medium to longish intervals. Typical calls varied, slightly buzzy, mechanical-sounding, e.g. “trrr-trrr-trrr” (rising, falling, rising); when alarmed, harsher, shriller “trrrh”, “trrrh”, “trrii” or “drrri” notes, doubled or in repetitive series, “trrii-trrii-trrii-trrii-trrii...”; also “trrrh-trrrh-trrrh” (with thinner, even shriller end note) and “trrrh-tih” or “trrrh-trrii” (with buzzy second note); contact calls include spaced “tip” notes.

**Habitat.** Mixed broadleaf scrub, dense prickly oak (*Quercus*) mixed with willows (*Salix*) and other trees, scrub and secondary growth in open forest and along its edge; sometimes reedbeds in or near forest or bamboo. Recorded at 1000–3300 m.

**Food and Feeding.** No information on diet. Usually in small flocks of up to 15 individuals, sometimes as many as 40, outside breeding season. Forages at low level in vegetation.

**Breeding.** Season Jun–Aug. Observation of food-carrying by both members of a pair suggests that young are fed by both sexes. No other information.

**Movements.** Sedentary.

**Status and Conservation.** Not globally threatened. Not well known. Has rather limited range in C China, where generally considered to be rather uncommon. Recorded regularly at Wolong Nature Reserve, in C Sichuan, and Jiuzhaigou Nature Reserve, in NC Sichuan; present also in Foping Panda Reserve, in Shaanxi.

**Bibliography.** Anderson (2003), Appleby *et al.* (1989), Bangs & Peters (1928), Cheng Tsohsin *et al.* (1965), Dedičius (1897), Deignan (1964c), Hanert (1907), Hornsø (1999), Inskipp *et al.* (1996), Laurie *et al.* (1986), Massie & Massie (1997), Meyer de Schauensee (1984), Sien Yaohua *et al.* (1964), Stresemann (1923c), Thayer & Bangs (1912), Vaurie (1972), Yu Zhiwei *et al.* (1986), Zheng Xuoxin & Qian Yanwen (1973).

## 10. Vinous-throated Parrotbill

*Paradoxornis webbianus*

**French:** Paradoxornis de Webb **German:** Braunkopf-Papagei **Spanish:** Pícoloro de Webb  
**Other common names:** Webb's Parrotbill, Webb's/Rufous-headed/Brown Crowtit

**Taxonomy.** *Suthora webbianus* Gould, 1852, Shanghai, Jiangsu, China.

Sometimes placed together with *P. conspicillatus*, *P. brunneus*, *P. alphonisianus*, *P. zappeyi*, *P. przewalskii*, *P. fulvifrons*, *P. nipalensis*, *P. verreauxi* and *P. atrosuperciliaris* in a separate genus, *Suthora*. Considered conspecific with *P. brunneus* and, especially, *P. alphonisianus* by some authors. Where range overlaps with that of latter, the two species are sometimes found in mixed flocks in which occasional hybrids reported, e.g. in Vietnam (near Sa Pa, in W Tonkin), and hybrids seen also in NW Italy (where both species introduced); in China, interbreeding reported in 1938 in C Sichuan, and a number of earlier specimens from that region were considered to present a range of features intermediate between the two species, but insufficient details available. Race *suffusus* poorly marked, perhaps better united with nominate; *elisabethae* doubtfully distinct from *suffusus* (exact SW geographical limits of which are unclear), and the single type was a specimen in full moult (colour, which varies considerably with wear, an unsatisfactory character for racial diagnosis). Entire Korean population included in race *fulvicauda*, but those in extreme N possibly belong with *mantschuricus*. Six subspecies currently recognized.

**Subspecies and Distribution.**

*P. w. mantschuricus* (Taczanowski, 1885) – extreme SE Russia (S Ussuriland) and NE China (E Heilongjiang S to NE Hebei).

*P. w. fulvicauda* (C. W. Campbell, 1892) – E China (W & S Hebei) and Korea.

*P. w. suffusus* (Swinhoe, 1871) – C & SE China (S Gansu, S Shaanxi, C & E Sichuan, E Guizhou and Guangxi) to S Shanxi, inland S Jiangsu, W Fujian and Guangdong) and extreme N Vietnam (NW part of N Tonkin).

*P. w. webbianus* (Gould, 1852) – coastal Jiangsu and N Zhejiang, in E China.

*P. w. elisabethae* (La Touche, 1922) – extreme S China (SE Yunnan) and extreme N Vietnam (N part of W Tonkin).

*P. w. bulomachus* (Swinhoe, 1866) – Taiwan.

Introduced in Europe (NW Italy).

**Descriptive notes.** 11–12.5 cm; male 8.5–11 g, female 7–12 g (*suffusus*, *fulvicauda*, *mantschuricus*). A relatively small and long-tailed parrotbill. Nominative race in fresh plumage (Nov.) has rufescent-brown forehead to crown merging with upperpart colour on nape/uppermost mantle, lores buffier than crown; upperparts warm-tinged mid-brown, slightly buffier on uppertail-coverts; flight-feathers and tertials dark brown with buffish-cream inner edges, outer fringes of secondaries and primaries strongly rufous-chestnut, paler and buffier on last two-thirds to three-quarters of fringe (towards tip) on primaries P7–P9, then gradu-

ally decreasing towards feather tips on inner primaries, outer fringes of tertials buffier than those of secondaries; upperwing-coverts appear roughly intermediate in colour between upperparts and wings; uppertail dark brown, with outer feather fringes similar in colour to upperparts (particularly towards bases); ear-coverts to throat and upper breast pinkish-cream with rather faint warmish brown streaks, flanks and undertail-coverts similar in colour to upperparts but paler and buffier, abdomen centre more buffish-cream and merging with breast colour; iris brown to pale grey; bill dark slate coloured with lighter tip of lower mandible, or brown with yellow tip; legs greyish-brown. Sexes alike. Juvenile is darker and more uniform above than adult, with less bright and contrasting crown, slightly warmer upperparts, plainer and buffier underparts with less pink and less obvious streaking. Races differ mainly in tone of colours: *suffusus* is slightly brighter than nominate, more rufous-chestnut on crown to uppermost mantle, a shade colder/darker above, perhaps slightly warmer and more intense vinous-pink below; *elisabethae* is similar to previous, but with somewhat darker and more chestnut forehead to uppermost mantle, somewhat duller throat and upper breast with less distinct streaks, and buffier belly (also, bill described as dull greyish and legs as bluish dusky-pink or reddish-tinged dull greyish); *bulomachus* is also very similar in appearance, but has considerably larger bill (supposed paler rosy head side contrasting with pinkish rufous-chestnut crown, and very pale throat, not obvious on museum specimens examined); *fulvicauda* has pinkish of underparts very slightly stronger, and reaching farther down towards belly, rufescent brown of nape possibly more chestnut and may extend farther onto upper mantle; *mantschuricus* is noticeably paler overall, with less obvious streaking on head side and throat, weaker pink tinge below. Voice. Song (race *fulvicauda*) can be transcribed as “rit-rit chididi tssu-tssu-tssu” or “ri rit ri chididi wii-tssu-tssu” (2–5 soft quick introductory notes, then very rapid “chididi”, and finally loud high, thin stressed notes). Flocks call with subdued rapid chattering, interspersed with occasional thin, high piercing “tsiu-tsiu” or “tiu-tiu” (*elisabethae*), and chuntering “chr’rr’rr” and “chur’ir’it” etc.; more scolding calls when agitated, e.g. “wutitit”, and “wutitich’it’it’it’it” (*suffusus*).

**Habitat.** Scrub, thickets, secondary growth, forest edges, early successional stages to relatively mature secondary woods, also hedges, bamboo groves, reeds, marshes, tea plantations, and plant nurseries. In most of Chinese range occurs only to 1400 m, and mainly below 1000 m in Sichuan, where replaced at higher levels by *P. alphonisianus*; 600–2000 m in S & SE China. Found at up to 1500 m in Vietnam. Reaches highest elevations in Taiwan, where recorded to 3100 m and thought possibly to occupy the widest niche of any bird species.

**Food and Feeding.** Feeds mainly on seeds, flowers, fruits and buds; also insects and their eggs, including locusts (Orthoptera) and caterpillars of geometrid moths (Lepidoptera). Insect food constituted only 37% of diet during studies in Taiwan, where individuals were seen to pick at leaves or stems of 40 different plant species. Lives in fast-moving flocks, which change in size according to season, small in Apr–Jun, middle-sized in Aug–Sept, large in Oct–Jan (up to 140 birds in Korea), and middle-sized in Feb–Mar; found in pairs from Mar to Aug (breeding season). Primarily an understory-dweller, but will ascend to canopy of small trees in search of certain flowers and seeds. In Taiwanese studies, this species spent 85% of its waking time in foraging or feeding.

**Breeding.** Apr–Aug; multi-brooded, often two broods during one season. Monogamous; duties of nest-building, incubation of eggs and rearing of young shared more or less equally by the two sexes. Nest, constructed during period of 1–4 days, a neat and fairly stiff, deep cup-shaped structure (rounded or oblong) made from coarse and fine grasses, strips of rush (*Juncaceae*) leaves, dry bamboo or other leaves, culled *Stephanandra* (*Stephanandra incisus*) bark (S Korea), plant fibres, strips of whitish reed skin, dry twigs and fine roots, sometimes wrapped in long soft moss and/or plastered with cobweb where available, lined with fine grass stems, very fine grass blades, cow fibre, hair, feathers and the like (Korean nests apparently never have feathers or mammal hair in lining), the rim often well finished-off and plastered with cobweb; external diameter 6–11 cm, height 6–12 cm, internal diameter 4–6.5 cm, depth 4–1–9 cm, second-brood nests apparently on average smaller (though similar in shape) than first-brood ones; situated 30 cm to 3 m (mostly 40–90 cm) above ground among reeds, small bamboos, nettles (*Urtica*), climbing plants, or in fork of bush, including tea (*Camellia sinensis*), or small tree (141 nests in S Korean surveys were built in 28 different plant species, including trees, shrubs, herbs and grasses). Clutch 3–7 eggs (usually 5–6 in S Korea, 4–5 in China and Taiwan), first egg laid on day following nest completion or several days thereafter, eggs smooth and slightly glossed, morphologically variable, azure to turquoise-blue, bluish-white or white, dimensions 15.5–16.7 × 11.7–12.7 mm (*elisabethae*), 14.2–17 × 11.2–13 mm (*suffusus*), 16–17.8 × 12.3–13 mm (*fulvicauda*), 14.9–16.4 × 12.2–12.8 mm (*mantschuricus*), and average 16.5 × 13.2 mm (*bulomachus*, eggs of which described as slightly darker and much broader than those of other races); apparently, *mantschuricus* and *bulomachus* lay only blue-type eggs, and blue-green eggs of *fulvicauda* said to be bigger than white ones and were typically the most common type found during surveys in S Korea (although the ratio varied from site to site); incubation period 13–15 days, typically 14 days, hatching largely synchronous (of 57 broods studied in S Korea, 82.4% hatched completely within 24 hours, 15.8% within 48 hours, 1.8% after 48 hours); chicks leave nest after just 9–10 days, having attained c. 80% of adult body weight but only 60% of adult wing length. Nests commonly parasitized by Common Cuckoo (*Cuculus canorus*), e.g. 5.3% of nests at study sites over four seasons in S Korea; cuckoo's eggs are always of a blue type but larger than those of host, and host rejected more than 60% of cuckoo eggs when laid in blue-egg clutches and 100% when laid in white-egg clutches.

**Movements.** Some cold-weather movements recorded for race *mantschuricus* in Changbai Mts, in SE Jilin (NE China), where said to depart in late Sept and return in late Apr; according to some authors, this race roams from Sept to Mar Apr, and some altitudinal movements also suggested. Vagrism recorded in Japan (W coast of N Honshu). Has been postulated that high-flying behaviour in winter and spring may be linked with eruptive movements by pairs. Post-fledging dispersal of young takes place soon after independence, when they leave natal site with others of species and

move to non-breeding range. No definite dispersal pattern noted during Taiwanese studies; even when juveniles moved to join a new flock, it was usually the one adjacent to parental flock.

**Status and Conservation.** Not globally threatened. Common and very widespread. Has adapted to a variety of semi-natural and man-modified habitats. Away from natural range, small feral populations appear to be establishing themselves in NW Italy, having been released from captivity by cagebird-traders: at Palude Brabbia Regional Nature Reserve and Ramsar Site, in Varese (Lombardia), this species occurs in mixed flocks with similarly introduced feral *P. alphonsianus*, although latter is much the commoner; also, at least two individuals were trapped during 1990s in Val Campotto-Vallesanta Nature Reserve, on Italian Adriatic coast.

**Bibliography.** Anon. ## 11. Brown-winged Parrotbill

### *Paradoxornis brunneus*

French: Paradoxornis à ailes brunes

Spanish: Picoloro Alipardo

German: Braunflügel-Papageimeise

Other common names: Rickett's/Yunnan Parrotbill (*ricketti*)

**Taxonomy.** *Suthora brunnea* J. Anderson, 1871, Momien [= Tengchong], western Yunnan, China. Sometimes placed together with *P. conspicillatus*, *P. webbianus*, *P. alphonsianus*, *P. zappeyi*, *P. przewalskii*, *P. fulvifrons*, *P. nipalensis*, *P. verreauxi* and *P. atrosuperciliaris* in a separate genus, *Suthora*. Considered conspecific with *P. webbianus* (and *P. alphonsianus*) by some authors, but widely accepted treatment as separate species supported by differences in skeletal features of skull. Race *ricketti* has sometimes been given full species rank, but there is currently no evidence of overlap in range with other races, as previously suggested by some authors; further study needed. Ranges of nominate and *styani* meet at S end of Dali Valley, at least; has been commented that latter is possibly the result of secondary intergradation, but series of museum specimens examined appeared very uniform in plumage characteristics, suggesting that it is a valid race. Three subspecies recognized.

#### Subspecies and Distribution.

*P. b. brunneus* (J. Anderson, 1871) – E (E part) & C (E part) Myanmar E to S China (W & NW Yunnan W of Lijiang Range and L Er Hai).

*P. b. styani* (Rippon, 1903) – Dali region, in NW Yunnan (S China).

*P. b. ricketti* Rothschild, 1922 – SW Sichuan (from Yalong Jiang) SW to NW Yunnan (to Lijiang Range and area E of L Er Hai), in S China.

**Descriptive notes.** c. 12–13 cm; male 8–13 g, female 6–10 g. Nominative race has bright chestnut crown to uppermost mantle and head side, contrasting with warm dark brown upperparts; upperside and tail similar to upperparts, remiges with pale outer fringing that is ashy to buffish on primaries (except two outermost); throat and upper breast vinous with darker chestnut streaks, well demarcated from pale belly, and rest of underparts buff-tinged (particularly in centre); iris brown, becoming red-brown in breeding season, orbital skin white; bill brownish-yellow to whitish-yellow, culmen blackish; legs greyish or grey-brown to pale olive. Distinguished from *P.*

*webbianus* mainly by brighter crown contrasting more with upperparts, plainer wings lacking chestnut, darker chestnut streaks on throat and breast, more buff-tinged below. Sexes alike. Juvenile differs from adult in having forehead to uppermost mantle duller and paler, appearing more concolorous with rest of upperside, which is darker and more rufescent, underside much buffier (particularly on belly and vent) and more uniform, with less obvious streaking. Race *ricketti* differs from nominate in darker chestnut crown to uppermost mantle, somewhat greyer upperparts (exact difference obscured by lack of fresh-plumaged specimens), pinkish-white throat and breast (streaks consequently very obvious and contrasting, also somewhat bolder), and paler remainder of underparts; *styani* is more or less intermediate between other two, but plumage below closer to previous. Voice. Keeps up a continuous twittering when feeding; no other information.

**Habitat.** Scrub and grass, thickets, sometimes in open forest or along forest edges; montane species, found at 1525–2375 m in Myanmar and 1830–2800 m in China.

**Food and Feeding.** Feeds on grass seeds; known to ingest some grit and sand. Outside breeding season occurs in pairs or fast-moving foraging parties, which may contain up to 35 or more individuals.

**Breeding.** Apr–Jun. Nest described as a rather deep, compact cup-shaped structure made from grasses, sometimes plastered with a little moss, lined with finer grasses, horsehair and similar, and situated up to 60 cm above ground in grass or rushes, brambles (*Rubus*) among grass, or a thick bush or tangle of creepers. Clutch 2–4 eggs (usually 3 in Myanmar), unmarked pale blue or fairly deep blue, with dimensions (in Myanmar) 15.2–17.5 × 12.7–13.5 mm. No other information available.

#### Movements.

**Status and Conservation.** Not globally threatened. Restricted-range species: present in Yunnan Mountains EBA. Generally uncommon to fairly common in suitable habitat throughout its very limited range.

**Bibliography.** Anon. (1980a), Bangs (1932), Deignan (1964c), Greenway (1933), Han Lianxian (1991), Harrington (1909, 1914a), Inskipp *et al.* (1996), McCarthy (2006), Meyer de Schauensee (1984), Riley (1926), Rippon (1903), Robson (1989c), Rothschild (1923, 1926), Smythies (1940), Stanford (1935), Stanford & Mayr (1940), Stanford & Ticehurst (1935, 1938), Stone (1933), Stuart Baker (1922), Tan Yaukuang & Cheng Tsohsin (1964), Traylor (1967), Vaurie (1959).

## 12. Ashy-throated Parrotbill

### *Paradoxornis alphonsianus*

French: Paradoxornis à gorge cendrée

German: Graukehl-Papageimeise

Spanish: Picoloro Gorgijrís

**Taxonomy.** *Suthora Alphonsiana* J. Verreaux, 1870, “les montagnes du Thibet chinois”; type from Chengdu, Sichuan, China.

Sometimes placed together with *P. conspicillatus*, *P. webbianus*, *P. brunneus*, *P. zappeyi*, *P. przewalskii*, *P. fulvifrons*, *P. nipalensis*, *P. verreauxi* and *P. atrosuperciliaris* in a separate genus, *Suthora*. Considered conspecific with *P. webbianus* and *P. brunneus* by some authors. Where range overlaps with that of former, the two species sometimes form mixed flocks in which occasional hybrids reported, e.g. in Vietnam (near Sa Pa, in W Tonkin), and hybrids seen also in NW Italy (where both species introduced); in China, interbreeding reported in 1938 in C Sichuan, and a number of earlier specimens from that region were considered to exhibit a range of features intermediate between the two species, but insufficient details available; has been suggested that race *ganluoensis* is one such intermediate form, but this highly unlikely, as its range is not in the overlap zone but closer to that of *P. brunneus*. Race *stresemanni* has sometimes been merged with nominate, but is much closer to, and possibly synonymous with, *yunnanensis*. Introduced birds of present species in Europe may represent an undescribed race; further study required. Four subspecies recognized.

#### Subspecies and Distribution.

*P. a. alphonsianus* (J. Verreaux, 1870) – C & SC Sichuan, in C China.

*P. a. ganluoensis* Li Guiyuan & Zhang Qingmao, 1980 – Ganluo region of SC Sichuan (China).

*P. a. stresemanni* Yen Kwokying, 1934 – Guizhou and adjacent SE Sichuan, in SC China.

*P. a. yunnanensis* (La Touche, 1921) – extreme S China (SE Yunnan) and extreme N Vietnam (NW Tonkin).

Introduced in Europe (NW Italy).

**Descriptive notes.** 12.5–13 cm; 8–13 g. Nominative race has chestnut crown to nape sharply demarcated from cold dark brown upperparts; upperside and tail dark brown, flight-feathers and tertials fringed dark chestnut; lores to head side, neck side and breast quite dark brownish-grey, throat greyer still, with rather narrow dark streaks, flanks cold dark grey, centre of abdomen duller; iris pale grey or bluish-grey to brown; bill dusky flesh-coloured; legs flesh-coloured. Differs from *P. webbianus* mainly in more sharply defined chestnut crown to nape, darker upperparts, darker chestnut fringing on wings including outer tertial fringes, lack of

any obvious vinous-pinkish on head side, throat and breast, which are much greyer. Sexes alike. Juvenile is more uniformly chestnut-tinged above than adult, has somewhat paler and browner head side and paler, more uniform and buffier underparts. Race *yunnanensis* is somewhat brighter than nominate on crown, nape and wing fringing, has upperparts warmer-tinged, side of head/neck purer grey (contrary to some published statements, head side not dull greyish-vinous nor dull greyish with vinous wash), base colour of throat and upper breast paler or whiter, remainder of underparts paler; *stresemanni* shows no obvious differences from previous; *ganluoensis* is said to differ from nominate in having cheeks and ear-coverts “chestnut-red”. Voice. Sings with loud, high-pitched series of 3–4 notes (usually 4 notes), delivered with varying rapidity, e.g. “tsu-tsu-tsu-tsu” or “tsse-tsse-tsse-tsse”, or “tsu tsu-tsu-tsu” (with uneven note spacing), also a longer series of “tsu” when excited (in response to tape playback); also “tsu-tsu-tsu-tsu-tsu-tsu”, with final note weaker. Calls include rather harsh, chuntering, sometimes scolding series, e.g. “twer-twer-twer-twer”, “twi-twi-twi”, “trr-ttr-ttr”, “tcher-der-der”, “chip-ip-ip-ip” and similar; contact calls very light “tu”, “twi”, “ti” and “du” notes, often rapidly combined; low purring “prrrr-ee” and “prrrr-ee” heard at close range.

**Habitat.** Scrub, grass, thickets, tea plantations, forest edge. Recorded at 1100–1500 m in Vietnam; 320–2350 m, locally as high as 2570 m, in China. Introduced population in Italy inhabits beds of common reed (*Phragmites australis*) and areas dominated by meadowweet (*Filipendula ulmaria*), early goldenrod (*Solidago gigantea*) and grey willow (*Salix cinerea*); apparently no documentation of the species’ occurrence in marshland in its native range.

**Food and Feeding.** Seeds. Except when breeding, found in fast-moving parties of 10–40 or more individuals; sometimes associates with *P. webbianus* in Vietnam. Introduced Italian population feeds on seeds, buds and insects, the last-mentioned being main food for young; during winter months, feeds on insects found on inside of common reed stems.

**Breeding.** Apr–Aug in China. Nest a cup-shaped structure made of bamboo or other leaves, grass, bits of fern, moss, cobwebs, bark, ears of wheat and the like, lined with fine grasses, palm fibre, wool, pigs’ hair and similar, external diameter 6–10.9 cm, height 6.5–9.2 cm, internal diameter 4–6.5 cm, depth 3.5–5.6 cm; placed in branch fork in small tree or bush, or in a clump of bamboo or grass, usually 0.5–1.5 m above ground. Clutch 2–6 eggs, usually 3–5, those of race *stresemanni* described as plain white, bluish-white, greenish-white or pale blue, 14.9–19 × 12–13 mm. No other information.

**Movements.** Sedentary. Although the feral numbers of the species have built up very quickly in NW Italy, the species is considered to be very slow in expanding its overall range there.

**Status and Conservation.** Not globally threatened. Considered to be fairly common throughout its rather restricted natural range in China and N Vietnam. In Europe, this species has recently become naturalized in NW Italy, at Palude Brabbia Regional Nature Reserve and Ramsar Site, in Varese (Lombardia), where it occurs in mixed flocks with similarly introduced feral *P. webbianus*, and is much the commoner of the two; population at Brabbia has risen from an estimated 24 individuals in 1995 to several hundreds ten years later; evidence also of range expansion there, with observations at two localities in nearby Lago di Varese area in Dec 1998. The naturalized Italian population could potentially pose a threat, through competition for food etc., to some scarce native species.

**Bibliography.** Anon. (2004c), Bangs (1932), Bangs & Van Tyne (1931), Boto *et al.* (2000), Cheng Tsohsin & Cheng Paolai (1960), Cheng Tsohsin, Tan Yaukuang & Li Yungshin (1965), Cheng Tsohsin, Tan Yaukuang, Liang Chunyu & Chang Chunfan (1963), Deignan (1964c), Dowell *et al.* (1997), Hartert (1907), Huang Qiang, Deng Heli & Mao Ke (1995), Huang Qiang, Huang Yongzhao & Deng Heli (1993), Inskipp *et al.* (1996), Kazmierczak (1990), King (1989b), La Touche (1923), Li Guiyuan & Zhang Qingmao (1980), Li Guiyuan, Liu Liangcai *et al.* (1976), Li Guiyuan, Zhang Qingmao, Luo Jiazai *et al.* (1994), Li Guiyuan, Zhang Qingmao & Wen Anxiang (1993), Liu Kezhi *et al.* (1994), McCarthy (2006), Meyer de Schauensee (1984), Robson (2000), Rothschild (1926), Schäfer & Meyer de Schauensee (1938), Stett (1993), Stresemann (1923c), Thayer & Bangs (1912), Traylor (1967), Uchida & Kuroda (1916), Wu Zhikang *et al.* (1986), Yen Kwokying (1934b), Zhang Quntan *et al.* (1994), Zheng Zuoxin *et al.* (1987).

## 13. Grey-hooded Parrotbill

*Paradoxornis zappeyi*

French: Paradoxornis de Zappey Spanish: Pícoloro Encapuchado  
German: Grauhauben-Papageimeise  
Other common names: Crested/Dusky/Zappey's Parrotbill, Dusky Crowtit

**Taxonomy.** *Suthora zappeyi* Thayer and Bangs, 1912, Wa-shan, near Hanyuan, Sichuan, China. Sometimes placed together with *P. conspicillatus*, *P. webbianus*, *P. brunneus*, *P. alphonstanus*, *P. przewalskii*, *P. fulvifrons*, *P. nipalensis*, *P. verreauxi* and *P. atrosuperciliaris* in a separate genus, *Suthora*. Two subspecies recognized.

**Subspecies and Distribution.**

*P. z. zappeyi* (Thayer & Bangs, 1912) – SC Sichuan (excluding Erlang Shan) and NW Guizhou, in SC China.

*P. z. erlangshanicus* Cheng Tsohsin *et al.*, 1983 – Erlang Shan, in SC Sichuan (China).

**Descriptive notes.** 12–5 cm; male 10 g, female 9 g. Distinctive parrotbill, with bushy crest reaching its peak above the eye. Nominative race has forehead to uppermost mantle mid-grey ("mouse-grey"), darkening somewhat towards forehead, which is also faintly streaked; lores to above eye dark grey to blackish, offsetting white eyering which is obscured with grey mark above/in front of eye and split by a thin dark line at front and rear; upperparts, including upperwing-coverts, slightly rufescent mid-brown, becoming somewhat paler or duller (perhaps buffier) on rump and uppertail-coverts; flight-feathers dark greyish to dark

brownish, with outer fringes similar in colour to upperparts; tail dark greyish to dark brownish-grey, outer fringes of feathers a duller version of upperpart colour; head side paler grey than hindcrown, merging into more ashy or whitish colour with buff tinge on throat and centre of upper breast, where shows faint greyish streaking; flanks and undertail-coverts warm buff, belly centre more pale greyish; iris dark; bill pale yellowish, basal half of upper mandible pinkish-grey to pale pinkish-horn; legs dark greyish to dark pinkish-grey or brownish-grey. Sexes alike. Juvenile undescribed. Race *erlangshanicus* is said to differ from nominate in having paler grey forehead to uppermost mantle, with less distinct darker shaft stripes, duller rufescent-brown upperparts and wing-feather fringes, paler and less brownish-tinged fulvous rump and uppertail-coverts, much paler grey sides of head and neck, and much paler sides of abdomen and undertail-coverts. Voice. Song a thin, high, piercing "ss-s-s-si". Only calls recorded are harsh, abrupt, scolding, rather rasping "trr'ik" and "trrrh" notes.

**Habitat.** Bamboo and bushes, including rhododendron (*Rhododendron*), in open mountain-top conifer forest, including fir (*Abies*) forest, and mixed fir–rhododendron forest; recorded only at 2350–3437 m, with one report from c. 1000 m (Wannan, on Emei Shan). Apparently restricted to open forest and scrub patches on exposed peaks and ridges near mountain tops.

**Food and Feeding.** Insects, including beetles (Coleoptera), and their pupae, also seeds; bamboo seeds may be important in diet. Found in small parties of up to ten individuals, foraging through low vegetation.

**Breeding.** May–Jun. Nest a relatively large, untidy, very deep cup-shaped structure made mainly of moss, lined with fine grasses, fine roots, and shreds of dead bamboo leaves, estimated external height 10–12 cm, internal diameter 6 cm and depth 8 cm; one was 50 cm above ground and woven around dead bamboo stems. Clutch 2–4 eggs, sky-blue in colour, reminiscent of those of Dunnock (*Prunella modularis*), estimated egg dimensions in one nest c. 15 × 10 mm. No other information.

**Movements.** May undertake minor altitudinal movements coinciding with hard weather or bamboo die-off.

**Status and Conservation.** VULNERABLE. Restricted-range species: present in Central Sichuan Mountains EBA. Locally common. Has so far been recorded from only nine places. Although considered to have a declining and severely fragmented population, there is currently no hard evidence to support this. In survey at Wawu Shan (Wa Shan) in 2003, 18 pairs found in area of 60 ha; on Emei Shan, described as not uncommon to common during period 1985–1998. Although status information rather lacking, these and other records indicate that this species can exist at fairly high densities in suitable habitat; its highly localized distribution and small number of localities, however, suggest that it could have a small total population. Main threat considered likely to be the loss and further fragmentation of its habitat, which is already naturally localized and fragmented. Substantial areas of forest have been lost within its overall range, but unclear whether the general reduction in forest cover has affected this high-altitude species. On Emei Shan, the limited area of open forest and scrub inhabited by this species was partially cleared in 1998 for construction of a tourist railway, and, once this is completed, increased number of tourists visiting the summit could negatively affect its habitat; possible also that periodic flowering and die-off of bamboo, in combination with habitat fragmentation, may affect its total population. Has been recorded from Emei Shan Protected Scenic Area, Mabian Dafengding Nature Reserve and Meigu Dafengding Nature Reserve, in Sichuan; may well occur also in Caohai Nature Reserve, in Guizhou, but it is apparently unclear whether suitable habitat exists within the reserve boundaries.

**Bibliography.** Anon. (2003c, 2006d), Butchart & Stattersfield (2004), Cheng Tsohsin (1987), Cheng Tsohsin, Li Jianxun & Zhang Ungmao (1983), Cheng Tsohsin, Tan Yookang *et al.* (1983), Collar *et al.* (2001), Deignan (1964c), Inskipp *et al.* (1996), King (1989c), Meyer de Schauensee (1984), Stattersfield & Capper (2000), Thayer & Bangs (1912), Wu Zhikang *et al.* (1986), Zheng Guangmei & Wang Qishan (1998).

## 14. Rusty-throated Parrotbill

*Paradoxornis przewalskii*

French: Paradoxornis de Przewalski Spanish: Pícoloro de Przewalski  
German: Przewalskipapageimeise  
Other common names: Grey-crowned/Przewalski's Parrotbill, Grey-crowned Crowtit

**Taxonomy.** *Suthora przewalskii* Berezowski and Bianchi, 1891, Hsiku and Minchow districts [presumably = Zhuguo and Min Xian Counties], southern Gansu, China.

Sometimes placed together with *P. conspicillatus*, *P. webbianus*, *P. brunneus*, *P. alphonstanus*, *P. zappeyi*, *P. fulvifrons*, *P. nipalensis*, *P. verreauxi* and *P. atrosuperciliaris* in a separate genus, *Suthora*. Monotypic.
